One of the most terrible examples of the effects of drunkenness and its accompaniments in promoting the spread of cholera was associated with the terrible outbreak at Liverpool in July 1866. Dr. Trench, the Medical Officer of Health, received information on Monday, July 2nd, that a death from cholera had occurred on the previous evening. This was the first case, the victim being an Irishwoman. The friends resolved on waking the corpse. The body was laid on a board; and in the apartment, scores of persons (men, women, and children) ate, drank, and slept, the orgies being kept up, amid drunken and profane revelry, during day and night. The whole place reeked with the loathsome and disgusting emanations of drunken and unwashed bacchanals. Drunken women squatted thickly on the flags of the court, before the open door of the crowded room where the corpse was laid. Before a week had passed, the husband of the woman was among the dead; and before the end of July, forty-eight persons had died from cholera within a radius of a hundred and fifty yards from the court which had been the scene of the ill-timed revelry.

Numerous facts teaching a similar lesson could easily be added; those cited will, however, suffice to show that, in taking means for preventing the advent or spread of cholera, the utmost efforts should be used by the authorities for limiting the facilities for procuring intoxicating liquor. When an attack is impending, intemperance ought to be most stringently dealt with. The drunkard is a source of the greatest danger to himself and to the community. The utmost efforts of the authorities, and the most lavish expenditure of funds, may be neutralised by the reckless conduct of a few intemperate persons. Every means ought therefore to be taken in order to prevent drunkenness.

It is not intended to imply that the attention of the authorities should be confined to the promotion of temperance—every hygienic method should be employed; but incentives to intemperance must be especially repressed—indeed, as far as may be practicable, suppressed.

## ON THE TREATMENT OF ANEURISM BY COMPRESSION.\*

By RAWDON MACNAMARA, M.D., F.R.C.S.I.,

Surgeon to the Meath Hospital, etc.

It may perhaps be in the recollection of some of the members present of this great Association, that upon the occasion of their honouring my native city, Dublin, with a visit, I read a paper in the Surgical Section on the Deligation of the Femoral Artery, in what is now known amongst surgeons as Porter's space. Upon that occasion I supported my views as to the eligibility of selecting this space as the site for operation by a record of eight cases, in six of which the operation had proved eminently successful, whilst in two the results had proved fatal, but fatal from causes perfectly independent of the site selected for operation. This paper will be found in the *BRITISH MEDICAL JOURNAL* for the year 1867, vol. ii, p. 285. Since then I have had no further personal experience of this operation; but I have learned from Professor Gross that since his return to America from the visit he recently paid these countries, he also has deligated the artery in this space with success, and that it is his intention to introduce a description of this operation into the forthcoming new edition of his well known *System of Surgery*. My inability to support this mode of procedure by a further record of additional cases is to be accounted for by the fact, that all the cases of popliteal aneurism which I have witnessed in the interval have proved amenable to treatment by compression. Even within the month just passed two cases have been successfully so treated in the wards of the Meath Hospital—one by Mr. Porter, the other by Mr. Wharton; the former case being brought to a successful issue in thirty-two days, the latter in seven days.

The treatment of aneurism by compression has been attended with such happy results in the hands of Irish surgeons—results contrasting in so marked a manner with the exceptionally favourable cases occurring in the practice of English surgeons—that I have on more than one occasion been asked by eminent London authorities how I could account for this discrepancy. To enable me to answer this question at all in a manner satisfactory to myself, I shall give a brief sketch of this mode of treatment since its revival in Ireland up to the present moment, and I shall lay before the Section several of the instruments which have been employed for the purpose during that period. By such a course I hope to clothe my observations at all events with somewhat of historic interest: and here, gentlemen, I beg of you to observe that I have used the phrase "*revival in Ireland*"; to do otherwise would be but to display a gross ignorance of the literature of the subject, inasmuch as that Irish surgeons cannot lay claim to absolute originality in the matter. In our earliest surgical writings we find recorded cases so treated. Not to go further back than Galen and Rhazes, we find these worthies using pressure in the treatment of aneurisms occurring at the bend of the elbow; whilst in more modern times, in the year 1772, Guattani published a treatise on aneurism, in which he records the results of this plan of treatment in eleven cases of popliteal aneurism, in five of which there was a successful result. So that we cannot claim for Irish surgery absolute originality in the matter; but we can claim for it the merit of its revival—of unwearied study of the subject—of having established the principles whereby the cure is effected—and of the suggestion of numerous most ingenious improvements in the class of instruments suited for the successful conduct of such cases. Pre-eminent amongst these labourers must always stand the names of Bellingham, Carte, and Tufnell; and to this latter gentleman am I indebted for being able to exhibit to you many of the most interesting of the instruments now lying upon the table.

Historically, the treatment of aneurism by compression may be divided into two eras—one anterior, the other subsequent, to the year 1785—a year memorable in our annals as that in which John Hunter per-

\* Read before the Surgical Section at the Annual Meeting of the British Medical Association, in Plymouth, August 1871.

formed the first of those operations for the cure of popliteal aneurism which will bear his name so long as civilisation lasts. In the first of these eras the pressure was applied directly over the aneurismal tumour, the object being to empty the sac of its contents, with the view of bringing the edges of the wound or slit in the vessel into apposition, so as to cause their adhesion and thereby to cure the disease. However faulty were both this theory and mode of treatment, undoubtedly successful results occasionally ensued. Why this should be so is capable of explanation did time permit; but more important matters press, and I must hurry on.

After Hunter's brilliant operation a long interval occurred, during which all such efforts as the cure of aneurism remained in abeyance until the year 1820, when Mr. Todd's now celebrated cases occurred in the Richmond Hospital. These cases are recorded in the third volume of the *Dublin Hospital Reports*, p. 121, *et seq.* In this paper Mr. Todd thus expresses himself: "The tumour was so much under the control of pressure on the inguinal portion of the artery, that I was not altogether without hope that, by diminishing the current of blood in the trunk of the artery, so as to favour the coagulation of the contents of the sac, a cure without operation might be effected." In both of these cases, however, recourse was subsequently had to deligation of the artery. In the year 1825, Mr. Todd for the third time employed pressure in the treatment of a case of popliteal aneurism, and upon this occasion with success; but his premature death interrupted his labours, and indeed prevented his placing this case upon record; and probably it would long since have been forgotten had it not been communicated to the profession by his son, the late lamented Dr. Robert Todd, in the pages of the *Dublin Quarterly Journal*, in the year 1846; the case being recalled to memory in consequence of the fact that Irish surgeons were then becoming sensible of the value of this mode of treatment, through the earnest exertions of the late Dr. Bellingham, whose masterly treatise on the subject is well worthy of careful study. As bearing upon this subject, I should also wish to direct your attention to Mr. Tufnell's work upon aneurism, the pages of which are enriched with several interesting plates illustrative of many of the instruments employed in this plan of treating aneurism.

The period of the *renaissance* of this plan of treatment was marked shortly afterwards by what must always be recognised as an important epoch in the treatment of aneurism by compression, to wit the superaddition of elasticity to pressure in the controlling power. From the very earliest period up to then, *dead* pressure alone had been employed, and the sufferings resulting therefrom were alone sufficient to baffle the best directed efforts of the most zealous and intelligent surgeon, and to exhaust the endurance of the most heroic patient—so much so as in numerous cases to induce them loudly to call out for deligation of the artery, thus reversing those well known lines—

—rather bear those ills we have,  
Than fly to others that we know not of.

To Dr. Carte must be attributed the merit of suggesting an instrument in which pressure of sufficient power could be combined with an amount of elasticity calculated to render that pressure tolerable.

Another and most important defect in the earlier instruments was, that no provision was made in their construction for altering the direction in which they were to exercise the pressure, and thus were they difficult of application and unsuited for general use. An instrument might control the artery in one individual, and yet fail altogether to do so in another; in fact, they were not suited for universal application: and even in such cases as those in which they were able to control the artery, their action was but temporary, as they were perpetually liable to displacement every time the patient shifted his position. To Mr. Read, the well known cutter in Dublin, is due the merit of meeting this difficulty, by adopting in our more recent instruments the ball- and socket-joint and the pelvic cradle. Since then Mr. Read has introduced to our notice another instrument which bears his name—"Read's compressor"—of the merits of which it would be difficult to speak in too eulogistic terms. This is the instrument which was mainly instrumental in effecting the cure in the two cases of popliteal aneurism already alluded to as having been successfully treated last month in the wards of the Month Hospital. In it, in my opinion, are combined the *ne plus ultra* of all that should characterize a good compressor—directness and permanence of pressure, associated with the requisite amount of elasticity.

A radical defect in our earlier efforts at curing aneurism by compression was, that the pressure was restricted to but one portion of the artery. Bellingham pointed out to us this error, and all subsequent experience has confirmed his teaching. Now-a-days we supplement the pressure applied by means of a Carte's or a Read's compressor to the vessel in the upper portion of its course, by a second instrument such as Signorini's or Salt's tourniquet, or some one or other of those

instruments constructed on the clamp principle, applied to the artery some three inches lower down. Thus are we enabled, when the pressure becomes even irksome in one situation, to remove it to another, and, by thus alternating it, to impede the ingress of the blood into the aneurismal sac, and thereby to allow the cure continuously to progress; for, be it well understood, one pressure is not relaxed until the other is brought into play.

A mistaken idea also pervaded our earlier efforts at the cure of aneurism by compression, that, to cure the disease, it was essential to cut off *entirely* the supply of blood to the sac. The fallacy lurking in this theory, so plausibly supported, as it was thought, by the analogy existing between the *modus curandi* of this plan of treatment and of that at the time attributed to the ligature, was also exposed by Bellingham. No theory more obnoxious to the satisfactory carrying out of this plan of treatment could have been promulgated. In the first place, it would render necessary an amount of pressure which, on its application painful, would quickly become intolerable. In the second place, it is absolutely antagonistic to the pathological conditions which must be established to assume a successful issue—the deposition in the aneurismal sac of successive layers of the fibrine of the blood. To secure this, a feeble current of blood through the sac is not only desirable, but essential; and therefore is it that an amount of pressure which would command the complete circulation through the artery is not only uncalled for, but is absolutely prejudicial to the ultimate cure. How important becomes a knowledge of this fact in the practical use of compression, will presently appear.

Another error which long prevailed was, that firm pressure should be applied through means of a roller to the entire extent of the limb; which roller, it was hoped, would act as an auxiliary to the pressure directed upon the vessel in the inguinal portion of its course. So far, however, from such pressure supplementing the cure, it actually obstructs it, inasmuch as it interferes with the establishment of the collateral circulation. Occasionally, also, too little attention was paid to the general condition of the patient's health. Anæmic and hyperæmic patients should not all alike be subjected to compression, without appropriate preliminary treatment. Long since have we learned in Ireland how certain such conduct would be to be attended with disappointing results.

From this hasty recapitulation of our earlier mistakes may be collected the plan upon which we now conduct such cases in Ireland. It may, however, prove useful to epitomise them. A case of popliteal aneurism presents itself for treatment. We determine to use compression. We first carefully ascertain the condition of the patient's general health. If anæmic or hyperæmic, we take appropriate measures; and, when we are satisfied upon this point, we apply some one or other of the most improved compressors—those in which the compressing power is modified by elasticity. With this we compress the artery in the upper portion of its course, having previously arranged, some three or four inches lower down, the auxiliary instrument by means of which we propose to alternate the pressure. The upper instrument is now made to control the artery, so as but just to arrest the pulsation in the sac. This is the most delicate step in all the procedure, and is regulated by the hand of an intelligent assistant, who at once informs us when the pulsation is arrested; and then and there the further application of pressure is arrested. A roster of intelligent students is now organised, and to them is entrusted the management of the case. Two are appointed to take charge of the patient for one hour, when they are relieved by two others, and so on during the day, whereby we secure unwearied attention during the period that pressure is kept up; and, as in Dublin we visit our hospitals at 9 o'clock A.M., the treatment generally commences about that hour, and is continued up to 9 o'clock P.M., when all pressure is removed, and the patient is encouraged to take his night's rest undisturbed. Next morning the treatment is resumed, and so on until the cure is perfected. At the commencement of the case, we take the patient into our confidence; explain to him the nature of his case and the method we are about to adopt for his cure, placing clearly before him the alternative, with all its possible dangers, which we should have to adopt in case compression should fail. The value of this procedure is very frequently demonstrated by the intelligent interest exhibited by our patients in the management of their own cases—so intelligent as in protracted cases to supplement, if not altogether to supersede, the supervision of them by our students. In the selection of our compressing force, we adopt in its widest sense the maxim "*Nullius in verba jurare in verba magistris*". Should one compressor prove irksome, we try another; if all should fail, we have recourse to digital compression, or to compression by means of weights; but, in every instance convinced of the soundness of this plan of treatment, we leave no stone unturned to secure its success.

As you will collect from the preceding remarks, gentlemen, every

exertion is made on our parts to conduct the case with as little inconvenience or pain to the patient as is possible. Pain in the seat of pressure we look upon as an evil; but there is a pain, and that sometimes for a few hours a very sharp pain, to the advent of which we anxiously look forward. I allude to pain in the neighbourhood of the knee-joint, which pain is the harbinger of cure. This pain is due to the rapid enlargement of the collateral circulation, dependent upon the diminished calibre of the aneurismal sac, encroached upon by the deposit in it of fibrine, and is best combated by narcotics.

So far, gentlemen, for our Irish plan of treating aneurism by compression: I now come to the question so often asked me, why we should be so successful, and you so much the reverse, in thus treating aneurism. I confess that the tone in which this question has occasionally been asked me has pained me very much. A doubt in the truthfulness of our statistics has not been openly expressed; still "*c'est le ton qui fait la musique*," and so with this question. This is a painful theme upon which to descant, as painful as I feel it to be unnecessary before such an audience as I have the honour now to address. The majority of our cases have been conducted not only in the presence, but with the assistance, of our students in our public hospitals. Under these circumstances, to attempt to colour the facts would be worse than a crime, for it would be a blunder. No! gentlemen, before you I feel that it would be a work of supererogation to attempt to vindicate the character of Irish surgeons for honour, truth, and loyalty to our common profession; whilst, on the other hand, to no man will I yield in profound reverence for what has been done in the past, what is being done in the present, by British surgeons, for the scientific progress of our profession. Therefore is it that I feel myself acquitted of any unworthy motive in placing on record my ideas as to why we should succeed and you should fail.

*First*, and above all, we have faith in the efficacy of our treatment, and reverently be it expressed, faith can do all things. Your experience can scarcely justify you in entertaining such faith.

*Second*. In this instance, at all events, the spirit of nationality pervades our ranks, and the humblest, the most indolent, the most apathetic surgeon amongst us, will try every expedient ere he will acknowledge that in his hands the Irish method of cure has failed.

*Third*. Our hospitals are visited at 9 A.M.; yours, I believe, at 2 P.M. By our arrangements we are enabled to visit our patient, and to commence his treatment under our personal supervision at an early period of the day.

*Fourth*. All our hospitals are within a few minutes' drive of the residences of their surgeons; thus are we enabled to pay during the day repeated visits to such cases, and so to watch them from hour to hour; and no matter how zealous, how intelligent, be the house-surgeons or the pupils, there is no eye equal to the master's for seeing that the work be done. That such surveillance imposes great trouble on the attending surgeon I freely admit, still it must always be borne in mind that it was *per tedia et labores* that this plan of treatment has been brought to its present perfection, and that *pour réussir il faut travailler*. You know best, gentlemen, your arrangements in these respects.

*Fifth*. Thoroughly aware, as we are, of the pathological changes which must be brought about in the contents of the sac to effect a cure, and convinced, as we are, of the principles whereby alone these changes can be produced, we are not afraid, during the night, to remove all pressure, and so to secure for our patients uninterrupted sleep, whereby we keep up their health to the condition most favourable for fibrinous deposit in the sac.

*Sixth*. And here I trust that I will not be considered as blowing too loud a blast on our Irish trumpet, I am of opinion that some of our success must be attributed to the intelligence of the patients whom we are called on to treat. Many are the instances in which their co-operation has proved to us of inestimable value. One of the class of instruments (the clamp) of which, even to the present day, we frequently avail ourselves, is due to the suggestion of a patient, a carpenter by trade, of the late Professor Harrison's; and, did time permit, numerous other instances of the truth of this assertion could be adduced.

Finally, the physique of our patients differs widely, I suspect, from yours. I fancy that the disease occurs, in the majority of English patients, in the persons of well-fed, robust, and plethoric individuals; such patients will require a compressing force of high tension; but as a rule it may be laid down that if the force employed exceed that which would be represented by a dead pressure of nine pounds, the pain to which it will give rise will soon render it intolerable. Our patients rarely, if ever, present such appearances; they rather incline to the opposite extreme—and when such is the case, we are obliged to call to our assistance good diet. 'Tis true that the plethoric individual may be reduced by regimen, etc., to the *juste milieu*. Still, after all, it is but human nature that we should find patients more amenable to a plan of

treatment which involves generous diet, than to one which enforces starvation and depletion.

Whatever be the motive, gentlemen, which actuates Irish surgeons in advocating this plan of treatment, there is one of which their history must hold them acquitted—pusillanimity. In a country where, within these past few years, the common iliac has been tied by Hargrave, the innominate laid bare by Porter, the abdominal aorta by Stokes, there must exist potent reasons for inducing such surgeons to prefer compression to deligation of the femoral artery. Irish surgeons may dare much in their operative proceedings, but one thing they must not do—submit a patient to a dangerous operation when they have at hand a procedure at once so simple, so effectual, so free from risk, as that to which I have so feebly drawn your attention this day.

## TREATMENT OF HÆMORRHAGE ARISING FROM RETENTION OF THE SECUNDINES AFTER ABORTION.\*

By J. G. SWAYNE, M.D.,

Physician-Accoucheur to the Bristol General Hospital, and Lecturer in Midwifery at the Bristol Medical School.

AN abortion about the middle of utero-gestation may become one of the most troublesome, difficult, and dangerous cases which can fall to the lot of the accoucheur. The reason is, that at this time it is peculiarly liable to be complicated with retention of the secundines. During the first two months of pregnancy, the aborted ovum is usually cast off entire, and there is seldom any further trouble. During the last three or four months, the membranes generally are ruptured, and the foetus and placenta expelled separately; but the latter is sufficiently bulky to stimulate the uterus to expel it; and, even if this should not happen, the uterus is large enough to admit of the introduction of the hand for the purpose of removing it. During the middle of pregnancy, however, or rather, I should say, during the third, fourth, and fifth months, the ovum is very likely not to be expelled entire: the placenta and membranes are not sufficiently bulky to induce expulsive efforts of the uterus, and are, therefore, very liable to be left behind; and the uterus is not large enough to admit the hand for the purpose of extracting them. Under favourable circumstances, the placenta and membranes may be cast off with, or immediately after, the foetus; but it is quite as usual, I think, to find that this is not the case, and that the secundines, if let alone, may be retained for an indefinite period. For instance, on making an examination, the accoucheur finds the uterus contracted in all its dimensions, and the os uteri tightly encircling the filiform funis, which will inevitably give way if any attempts are made to remove the placenta by its means. In fact, circular contraction of the fibres of the os uteri internum, or what is commonly called hour-glass contraction of the uterus, is a much more frequent occurrence after abortion than after labour at the full term, and is accompanied with similar dangers, although in a minor degree. As long as the placenta and membranes remain behind in the uterus, the patient is subject to attacks of hæmorrhage, which may be very frequent and very profuse; or she is liable at a later period to septicæmia from the absorption of putrid matter caused by the decomposition of the retained secundines.

To prevent such untoward results, the obvious indication is, of course, to remove the exciting cause; but this is a matter of so much difficulty in practice, that obstetric authorities have for a long time been divided in opinion as to the advisability of attempting it. The older authorities—for instance, Denman, Davis, Dewees, Burns, Ingleby, and Blundell—are in favour of the expectant plan, and disapprove of manual attempts to extract the placenta. Denman, who always relied so implicitly on the *vis medicatrix natura*, is especially opposed to manual interference, and at the same time very much underrates the risk arising from retention of the secundines, for he goes so far as to say, "Much less mischief may be expected from the retention of a putrid placenta than from attempts to force it away by the medicines usually given, or by manual assistance." I have myself in many instances tried the expectant plan of treatment, and can by no means give a favourable report of its results. As long as the placenta remains in the uterus, the patient is liable to sudden and alarming attacks of hæmorrhage; and so greatly am I impressed with the danger of this occurrence, that during the first three or four days after an abortion I would not on any account leave a patient with the placenta in the uterus, unless I had previously guarded against this accident by plugging the vagina. In all cases of miscar-

\* Read before the Medical Section at the Annual Meeting of the British Medical Association, in Plymouth, August, 1871.

riage accompanied with much hæmorrhage, the plug is a most valuable remedy, and may always be employed when the placenta cannot be extracted. It is a very safe remedy also, when certain precautions are taken. These are, to watch carefully that it does not occasion accumulations of blood, or retention of putrid matter, in the uterus. To fulfil the first indication, firm counterpressure should be made over the fundus uteri, so as to prevent the expansion of that organ. This is unnecessary during the first three months of pregnancy, as the uterus is too small to hold much blood; but during the fourth, and especially the fifth month, it becomes necessary, because the uterus is then capable of containing a considerable amount. I once attended a woman who miscarried during the fifth month, and who nearly died from internal hæmorrhage into the uterus, although the vagina had been plugged, and there was not the slightest escape of blood externally. She had lost a large amount of blood previously, and the quantity which then escaped into the uterus was nearly enough to turn the scale against her. Her case so impressed the danger of internal hæmorrhage on my mind, that I now never use the plug in the fourth or fifth months of pregnancy without applying over the fundus uteri a large cup-shaped piece of padded metal made for that purpose, and just adapted to the size of the organ. This is secured in its place by a strap and buckles, and over all an abdominal bandage. To fulfil the second indication—viz., to obviate the danger of collections of putrid matter in the uterus—the plug should be removed frequently, and reapplied if necessary. As a general rule, it is well not to let a plug remain *in situ* more than twelve hours. By far the most efficient method of plugging is to introduce into the os uteri a tent of compressed sponge before plugging the vagina. This not only prevents all escape of blood from the uterus, but most effectually dilates the cervix, and facilitates the extrusion of the placenta. The vagina should then be plugged; and for this purpose I generally prefer an old silk handkerchief, which has been previously torn into two or three long strips, and well oiled. It is much more convenient to introduce the plug through a full-sized tubular speculum. When the plug is pushed up by the fingers without using a speculum, the operation is much more tedious and painful. The plug should be removed after an interval of about twelve hours; and it is a good plan to administer a full dose of ergot about two hours previously. The result of this will probably be that, on removing the plug, the retained placenta will come away also; the stimulus of the plug and the ergot having induced expulsive action of the uterus. But yet, in many other cases, the action of ergot is very uncertain, and one's hopes are doomed to disappointment.

If the placenta does not come away, plugging may be continued for two or three days, if there be much danger of hæmorrhage, but if this is not the case, it is better not to persevere with it so long. When putrefaction of the secundines has come on, and the vaginal discharge has become very offensive, the plug should be taken away; and this is above all necessary if fever and constitutional irritation have set in. The plug, by confining putrid discharges within the uterus, renders the danger of absorption more imminent. To obviate this danger the vagina and even the uterus should be syringed out twice or three times a-day with warm water and antiseptic lotions, and this should be done quite as much with the view of detaching the placenta as of neutralising and washing away the putrid discharges. An ordinary Higginson's syringe with an elastic tube is the best instrument for washing out the vagina, and the nurse or other attendant may be directed to throw up about a pint of fluid each time. To syringe out the uterus, however, requires much more care and caution, as it is a proceeding by no means free from risk. I have seen very alarming symptoms, such as sudden acute abdominal pain, dyspnoea, and great prostration produced by injections into the uterus, especially when the fluid has been thrown up too forcibly and in too great quantity; and there is no doubt that in this way, not only some of the injection, but even some of the putrid uterine contents may be forced through the tubes into the abdominal cavity. On this account no more fluid should be injected than the uterus can easily contain; and the tube used for the purpose should not be so large as to prevent a free escape of the fluid by the side of it through the os uteri as soon as the uterine cavity is filled.

A small India-rubber bottle, to which an elastic catheter has been adapted, will be much better for uterine injection than a Higginson's syringe. I need scarcely say that this operation should not be entrusted to a nurse. Besides antiseptic lotions, astringents and styptics may be injected in the manner just described whenever hæmorrhage comes on after plugging has been discontinued. For this purpose an injection consisting of four ounces of the *liquor ferri perchloridi*, former of the *British Pharmacopœia* with twelve ounces of water, as recommended by Dr. Barnes, will be found very serviceable. I am in the habit of using a lotion consisting of one part of Bird's styptic (a peroxide of sulphate of iron and alumina) with four parts of water, and I prefer it to any other.

Besides these local means for checking hæmorrhage cold may be applied, and ergot of rye administered, together with various astringents. The recumbent posture should be strictly enjoined.

It must be confessed, however, by all who have had much experience of these cases, that the expectant treatment is very unsatisfactory; and that, in spite of plugging, styptics, and other palliatives, the patient is never safe from hæmorrhage, septicæmia, and other less dangerous consequences, so long as the *fons et origo mali* in the shape of the whole or any portion of the secundines is left behind in the uterus. She may suffer for weeks from severe hæmorrhages, frequent rigors, constant foetid vaginal discharges, hectic fever, night sweats, great prostration of strength, tenderness and swelling of the abdomen, and complete loss of appetite; and these symptoms may go on to a fatal termination\* unless the putrefying portions of retained placenta are either expelled naturally or removed by art. On this account most obstetric authorities in the present day have abandoned the expectant plan and are in favour of active interference.

In 1861 Mr. Priestley communicated to the Obstetrical Society of London an excellent paper on "the Treatment of Cases of Abortion in which the Placenta and Membranes are retained." In the discussion which followed, the weight of opinion in the Society was decidedly in favour of manual interference: Dr. Priestley, Dr. Hall Davis, Dr. Tyler Smith, and Dr. Tanner, all strongly advocating this plan of treatment, in which opinion I myself fully concur.

The propriety of manual interference being decided in the affirmative, the next question will be as to the best method of effecting it. Most authors maintain that the safest means is by the hand alone, and condemn (without, as I think, sufficient reason) the use of any kind of instrument for this purpose. As I remarked before, the uterus at this period of gestation will not admit the entire hand, and the most that we can do is to introduce the hand into the vagina so as to pass the fore and middle fingers into the uterus. Any attempts to extract a retained placenta, by two fingers, in the vagina only, will almost certainly be futile. Under the most favourable circumstances, the tips of the fingers may thus be able to touch the placenta just within the os uteri, but have little or no power to bring it down, and, in all probability, it will again and again elude their grasp. It becomes necessary, then, to introduce the whole hand into the vagina. But this is always a very painful operation at this period, even in a multipara, and in a primipara is accompanied also with considerable difficulty, and not free from danger. It is, therefore, always best to place the patient first under the influence of chloroform, as much for the purpose of relaxing their tissues as of abolishing pain. The *modus operandi* is thus described by Dr. Priestley: "Whilst the woman lies on her back, with the thighs flexed upon the abdomen, I have introduced one hand into the vagina, the other hand being placed over the fundus uteri, externally, to steady and depress it. If the os uteri was closed, it was gradually dilated by passing first the forefinger into the orifice, and then the second, with as little force as possible. With time and caution, the os uteri gives way to gentle pressure, and the introduction of the finger is in most cases not difficult. When the placenta is reached, it is separated in the ordinary way, and pushed downwards towards the palm of the hand, until it is partially or wholly beyond the os uteri. It is important, certainly, to ascertain that the placenta and membranes are entirely loosened from their attachments, and quite movable in the uterine cavity before the retraction of the hand, so that a second introduction of the fingers is not needed." Dr. Priestley further remarks: "In scarcely any case can it be necessary to introduce more of the hand into the uterus than the first two fingers—one may occasionally answer the purpose, but it works at great disadvantage alone, both in separating and extracting the placenta. The two fingers together constitute the best form of forceps for seizing what it is intended to withdraw, and are the most serviceable in all respects." With respect to the time that ought to elapse after the birth of the foetus, before the placenta should be extracted, Dr. Priestley is inclined to suggest that six hours may be fixed as an approximative limit, unless hæmorrhage have occurred to any extent during the interval. In such a case their removal should be effected earlier.

As far as my own experience goes, I cannot bear out the statements which have been made as to the efficiency of two fingers, either in dilating the os uteri, or extracting the placenta and membranes; I have several times failed, especially when the placenta has been at all adherent, in effecting these objects. This I attribute to the small powers of abduction and adduction which the fingers possess, even under ordinary circumstances. It is surprising how little power there is of grasping anything between the distal phalanges of the two first fingers, compared to

\* In the *BRITISH MEDICAL JOURNAL* for December 1868, Mr. Humphreys of Shrewsbury related a case of fatal flooding from retention of a piece of placenta only the size of a shilling.

that which is possessed by the forefinger and thumb. To test the relative powers of each, I have tried what amount of weight I could raise by the forefinger and thumb only, used as a forceps, and by the two first fingers. I found that, while I could raise twenty-eight pounds by the former, I could not raise more than four pounds by the latter. The reason, no doubt, for this great difference in power is, that when anything is grasped between the points of the thumb and forefinger, it is held by means of the flexor muscles; whereas, when it is grasped between the points of the fore and middle finger, it is held solely by the adductor muscles, which are much weaker and act much less advantageously. To show how little power the two first fingers have of grasping anything between them, let any one place the handle of an ordinary dining-room poker between their two distal phalanges, and he will find it no easy matter to lift it off the ground. One can readily understand that these two fingers, enclosed in a contracting uterus, would form but a very inefficient forceps.

On this account I have endeavoured to supply the deficient powers of abduction and adduction possessed by the fingers by means of a modification of the ordinary forceps which is used for extraction of the ovum. The extremities of the instrument form an obtuse angle, with the shanks so as to correspond with the angle formed by the axis of the uterus with that of the vagina. The extremities are fenestrated, and resemble in shape the blades of an ordinary obstetric forceps in miniature, except that they are more hollowed on their inner surface, so as to fit with tolerable accuracy over the forefinger of the left hand when it is placed between them for the purpose of introduction. Attached to the handles is a screw by means of which they can be powerfully separated when necessary. The instrument may thus be made a most efficient agent in dilating the os uteri.

The cases most adapted for the use of this forceps are those in the os uteri which will just admit the last phalanx of the index finger, and where the detached placenta can just be felt at the os uteri internum, but is found to be retained in that position by the contraction of the circular fibres of the os uteri. The forefinger of the left hand enclosed between the blades of the forceps, but with the tip advanced a little beyond them, should be passed through the os uteri until it touches the placenta. The blades of the instrument should then be passed in a little beyond the finger, and separated very slowly by the screw until the contraction of the circular fibres is gradually overcome. The placenta will then probably be extended until it can be grasped by the blades of the forceps, and if the cord is unbroken, this process may be facilitated by a little gentle traction upon it. In order to grasp the placenta, the screw must be turned in a reversed direction until the handles can be brought together.

Much has been said about the danger of passing instruments of this kind into the uterus beyond the guidance and protection of the fingers. I can readily understand that, with such an instrument as the wire crotchet of Dr. Dewees, it would not be difficult to injure the inner surface of the uterus when groping about for a retained placenta; but I cannot see how it would be possible to grasp any portion of the uterus with such a forceps as I have described when used with ordinary care; and the blades are so smooth and rounded externally, that they would not be likely to inflict injury in any other way. For my own part, I should not hesitate to employ this forceps, even when the placenta is still adherent to the fundus uteri. The advantages it possesses are that it dilates the os; and grasps the secundines better than the fingers, and that it renders the introduction of the entire hand into the vagina unnecessary.

**CONSTIPATION ATTENDING THE USE OF IRON.** To obviate the constipation liable to attend the use of iron, M. Béhier recommends a centigramme of powdered belladonna to be taken with ten centigrammes of sugar before meals—the dose of iron being taken with the meal. If, however, the belladonna produce disturbance of vision or dryness of the throat, the dose must be diminished; or a mild laxative may be given occasionally.—*Journal de Méd. et de Chir. Pratiques*, July 1871.

**TREATMENT OF BURNS.** M. de Bruyne recommends the following in cases of burns in place of the Carron oil and similar applications: fresh hydrate of lime, 3 grammes; glycerine, 150 grammes; chlorinated chlorhydric ether, 3 grammes. The mixture is transparent and uniform, and is applied to the injured part by means of a piece of fine linen, over which may be laid oiled-silk or other material to prevent evaporation. M. de Bruyne says that the treatment is equally applicable in cases of burn unattended with sloughing, and in those where sloughing has occurred and the eschars have fallen off. He believes that it will also be found useful in ill-conditioned wounds, and in tonic, callous, fungous, and foul ulcers. The quantity of the anæsthetic or of the lime may be varied according to circumstances.—*Journal de Bruxelles et Lyon Médical*, July 23.

## REPORT OF THE JOINT COMMITTEE OF THE BRITISH MEDICAL AND SOCIAL SCIENCE ASSOCIATIONS.

THE following report was read at the annual meeting of the British Medical Association at Plymouth, August 1871.

1. The whole of the oral evidence taken by the Royal Sanitary Commission having been now published, and their Report thereon, as well as on other documentary evidence (not yet published), having been carefully examined by us, we beg leave to offer the following remarks on the Report in general, and on certain portions thereof in particular.

2. We feel bound to express our views, because the Royal Sanitary Commission may be said to owe its existence mainly to our efforts, it having been appointed in compliance with a request, submitted on May 22nd, 1868, to Her Majesty's Ministers by a deputation from the above mentioned Associations, called together by us, introduced by Mr. George Clive, then M.P. for Herefordshire, and accompanied by several other members of Parliament.

3. But before entering upon a critical examination of some features of the Report, we desire to express our gratitude to the members of the Commission for the vast amount of labour and thought which they have devoted to this important inquiry, and our conviction of the general excellence of the work which they have now completed.

4. In their history of sanitary laws up to the present time—in their general observations on the subject of public health—in their exposition of some causes of present imperfection in sanitary administration—in their full appreciation of those injurious and morbid conditions of social life which tend to sap the vigour and destroy the health of the masses of our population—in their able summary of existing laws—and in many of their practical recommendations, especially those relating to the consolidation of law—we gladly recognise the value of their exertions, and the benefit they are likely to confer on the public by their prolonged investigation.

5. Having thus expressed a general opinion, we feel obliged to proceed to the far less agreeable task of pointing out certain primary defects in the method and scope of inquiry, and certain errors of conclusion which have naturally resulted from those defects.

6. The memorial which we presented to the Government in 1868 contains the following request:—"For all these reasons, and for others set forth in the accompanying 'Memorandum,' we ask for a thorough, impartial, and comprehensive inquiry, by a Royal Commission having power to visit, or to send Sub-Commissioners to visit, the large towns and other districts of the country, to obtain information and evidence, and to report on: 1. The manner in which the cases and causes of sickness and of death are and should be inquired into and recorded in the United Kingdom.—2. The manner in which coroner's inquests and other medico-legal inquiries are and ought to be conducted, particularly in regard to the methods of taking scientific evidence.—3. The operation and administration of sanitary laws, with special reference to the manner in which scientific and medical advice and aid in the prevention of disease are and should be afforded; and also with special reference to the extent of the areas or districts most convenient for sanitary and medico-legal purposes.—4. The sanitary organisation, existing and required, including a complete account of the several authorities and officers. The education, selection, qualification, duties, powers, tenure, and remuneration of the said officers to be specially reported on.—5. The revision and consolidation of the sanitary laws, having special reference to the increase of the efficiency of their administration both central and local." Into four of these subjects the Commission was expressly instructed to inquire, and to report thereon.

7. We observe with satisfaction that the Commission, like ourselves, "much regret that Scotland and Ireland were not included in the terms of the present, as well as of the former, Commission" (Memorandum, vol. ii, p. 360); but, admitting that the objections to the limitation of this inquiry to the provinces of England—objections which were submitted in a second memorial, dated July 1869—have been partially removed by the examination of eminent witnesses from the metropolis, from Scotland, and from Ireland, we beg to point out that the more important defect was further noticed in the last mentioned memorial, in the following terms:—"That no information obtained merely by written answers to schedules of questions, always open to grave misconception of their scope and import, and addressed exclusively to local authorities, can, in the absence of personal inquiry, either by the Commission itself or by skilled persons deputed to discharge its functions, furnish a trustworthy basis for permanent legislation. That as, sooner or later, recourse must be had in many places to inquiry on the spot, in order to supplement the tabular returns, as well as to test their accu-

racy, economy as well as efficiency demands that this course be adopted now.\*

8. Such inquiry would, we believe, have proved the necessity for a wider extension of administrative areas, as health districts, and for a more complete combination of the various functions of local government within those areas.

9. We observe that the Commission proposes to preserve and confirm, nay, even to augment the number of, existing local board districts, under what are called "urban" authorities; the minimum population of these districts being fixed at 3,000. Now, it is well known that petty elective authorities in small separate districts are apt to obstruct rather than forward sanitary improvement, and that for the most part they render any uniform and efficient system of administration almost impossible. This fact would, we believe, have been established indisputably by proper local inquiry. We had hoped, therefore, that all such local board districts would be combined and included in wider jurisdictions—even although the districts themselves, having been legally formed, might be separately represented in a larger board.

10. Estimating the number of local board districts from Parliamentary returns—and observing that an unreported, though considerable number of special drainage districts (some of which are little more than villages) are, according to the recommendations of the Commission, to be converted into local board districts—allowing also for the proposed creation of new districts of the same kind (see Report, p. 26)—we may reasonably conclude that the surface of the country would soon be, if it be not now, honeycombed by not fewer than 1,000 limited and isolated areas under "urban" authorities. Against such a project of local government, we strongly and earnestly protest.

11. We acknowledge that the Commission proposes to facilitate the combination of districts for limited purposes; but neither are the principles and terms of such combination (or joint action) defined in the Report, nor is its general necessity enforced; while its adoption is to be merely permissive, and left to the determination of either local or central authorities.

12. Whatever may be the nature of the district, or the extent and population of area which, on mature deliberation, shall appear to be the most desirable for purposes of local sanitary administration—and admitting that, outside of the larger towns, the Poor-law Union or Registration District may possibly offer superior advantages for this object—there appears to us no good reason why all the districts and authorities included within that area should not be combined under a single board of management for sanitary administration. The great majority of town districts in England are included in registration districts of a somewhat larger area. It is extremely important that the two or more governing bodies within that larger area should be united at the very least intermediately, by representation, for the purposes of the proposed Act.

13. The Royal Sanitary Commission having advised that all objects of local government, including the care of the public health and the relief of the poor, should be supremely directed by a single central authority,—it follows, if the propriety of such consolidation be admitted, that the same principle should be applied to all local authorities. But this appears not to be recommended by the Commission. For whereas, outside of "urban" districts, the management of the roads—unless the suggestion referred to in Resolution 12 be adopted—may continue under a different authority from that which is to administer the relief of the poor, the removal of nuisances, and the prevention of disease; yet, inside of "urban" limits, the relief of the poor might remain under a different authority from that which directs the management of the roads, the removal of nuisances, and the prevention of disease.

14. There might thus be two kinds of authority in urban districts, exercising different groups of functions from those exercised by the other two kinds of authority in rural districts. It cannot be doubted that this complication of authority and duty would lead to much administrative confusion, and hinder, as it has already hindered, the progress of improvement in local government. Not, if so-called "rural" authorities have to be constituted for all purposes, has any sufficient reason been shown why "urban" authorities should not act for the relief and prevention of disease, as well as for the relief and prevention of nuisances. It is very obvious, from their excellent remarks on "consolidation of areas of local government" (p. 53), that the Commissioners are fully aware of the great advantages which would result from the universal comprehension of all the various subjects of administration within the same districts.

15. We infer, not only from the evidence taken in this inquiry, but from well known facts, that "intermediate authorities", consisting of members not liable to be swayed by petty interests and trivial views, would be essential, on social, sanitary, and economical grounds, for

the higher purposes of sanitary administration. And, inasmuch as the authorities of counties have already to administer and enforce the law, to control institutions, to appoint officers, and to execute functions connected more or less with the health and safety of the people, we deem it highly desirable either that the powers of the magistracy (an existing authority) should be extended so as to comprehend the care of the public health, or that boards representing the magistracy and ratepayers in due proportion should be constituted for the direction and control of local sanitary administration. The magistrates would, of course, continue to sit as *ex officio* members of the boards in "rural" districts. It is no less reasonable and desirable that, if the division into "urban" and "rural" is to be maintained, they should take the same position on the future boards for the sanitary management of urban districts. We believe that the constitution, mode of election, and duties of local boards, whether for urban, suburban, or rural districts, should be uniform throughout the provinces of England.

16. There is no question of graver import or requiring greater attention than that of the compulsory acquirement of land by local authorities for certain purposes essential to the improvement of the public health. The treatment of this momentous subject by the Commission appears to us neither complete nor satisfactory. No general principles have been laid down as to the extent to which these powers should be granted; nor has the question been solved as to the mode of their purchase, in order on the one hand to protect the rights of owners so far as such protection may be consistent with the public safety, and on the other hand to save ratepayers from the great uncertainty and expense attending transactions of this nature under the present law. In what manner and on what conditions local authorities—whether those of large towns or those which might act over larger areas—should be empowered to provide sites for dwellings of labourers and artisans where densely populated parts of towns have been or may be demolished for purposes of public health (*e.g.*, under Mr. Torrens's Act)—whether such authorities should be empowered to acquire land for burial-grounds and mortuaries, for hospitals for fevers and other pestilences, for disinfecting establishments, for public slaughter-houses, for recreation-grounds, as well as for water-supply and for sewage utilisation,—these and other like questions require the most careful consideration, and are as yet left unanswered by the Commission.

17. For all these purposes and many others, involving both appeal and compulsion, an intermediate authority to consider and report on applications of local authorities would be invaluable. And moreover, we cannot too strongly urge on the Legislature the necessity of limiting the powers and functions of the central authority within the narrowest bounds consistent with effective action. Not only should local impatience of interference be considered and obviated by constitutional means, but a suitable authority, intermediate between the local and central, should be constituted in every county or sufficiently large area, as likely to be more cognizant of the wants and circumstances of every smaller district, and better able to judge of minute details inseparable from the daily working of Local Boards, than a government inspector.

18. The last important reason which we shall adduce for wider administrative areas is, that they would supply a superior machinery for the appointment of scientific officers, whether medical or engineering, of high and special qualifications.\* On these points we beg to refer to communications from two provincial physicians,† whose opinions on such a question are entitled to great consideration.

19. The Local Government Bill, brought in lately, and soon afterwards dropped, by the Right Honourable G. J. Goschen, M.P., contained, in Part iii, some important clauses relating to the constitution, jurisdiction, and business of County Boards. These clauses fully justify our remarks on this head, and lead us to hope that provisions similar in principle will form part of any future Bill for the amendment of local government and the creation of sanitary authorities.

20. We have now to examine those portions of the Report of the Sanitary Commission which relate to medical and scientific officers (Second Report, vol. i) in connexion with the "Memorandum on the Duties of Medical Officers of Public Health" (vol. ii), which expresses verily the principal needs and resources of local government in this respect.

21. With a large proportion of the statements and recommendations contained in these important documents we concur. Nevertheless there are principles asserted and suggestions made which appear to us open to serious objection.

22. It must be observed that the Memorandum (vol. ii) in treating of Medical Officers of Health, refers almost entirely to the Poor-law Medical Staff; while the Report, although accepting that staff as sufficient

\* See extract from Mr. Chadwick's Report. (See Appendix A.)

† See extracts from Dr. Strange's and Dr. W. Budd's letters. (See Appendix B and C.)

for rural districts (*i.e.* for those portions of unions which outlie the proposed Urban districts) treats more fully and specially of the Medical Officers of Health to be appointed by "urban" authorities; and the two series of proposals are by no means always consistent.

23. We have thought it advisable to compare both with two very important "Minutes" relating to the duties and qualifications of officers of health, which were successively issued by the General Board of Health. The earlier of these was signed by Lord Ashley (Earl of Shaftesbury), Edwin Chadwick, and T. Southwood Smith, soon after the appointment of the first Board. The later, dated December 20, 1855, was signed by the Right Honourable W. Cowper, President of the altered Board.\*

24. These able documents treat of the duties of the health officer, as distinct from those of the medical practitioner. The Report of the Commission assumes that such duties are, as a rule, to be performed only by the practitioner. The former refer to the higher, more special, and distinctive duties and relations of the office; the latter to the more common and subordinate. *We earnestly deprecate the present attempt to substitute this lower view of the office for the earlier and higher.*

25. The very position and duties of the Poor-law Medical Officers of this country at once point to the valuable assistance they would render to the chief officer of health of a district, as reporters of sickness and its causes; and as deputies and assistants in sub-districts their services would be indispensable. Our estimate of the functions to be discharged by the medical officer of health, of the special qualifications requisite, and of the time to be devoted to the discharge of these duties, contemplates a class of officers entirely special and without the distractions and difficulties which ordinary practice would necessarily entail.†

26. In the earlier "Minute" of the General Board of Health occurs the following sentence: [Not to extend to services provided for by private practice.] "Except in cases where existing disease may be alleviated by the immediate removal of any of the hereinafter specified causes, the general duties of the officer of health shall in no case comprehend treatment for the cure or alleviation of disease."

In the later "Minute" we find the following paragraph: "IV. The occupation of an officer of health will not usually be inconsistent with his devoting a portion of his time to certain other professional engagements; but, where possible, it will be well to debar him from the private practice of his profession:—first, because the claims of such practice would be constantly adverse to those of his public appointment, the duties of which (especially at times of epidemic disease, when his official activity would be most needed) private practice could scarcely fail to interrupt and embarrass; secondly, because the personal relations of private practice might render it difficult for him to fulfil with impartiality his frequent functions of complainant; and thirdly, because, with a view to the cordial goodwill and co-operation of his medical brethren, it is of paramount importance that the officer of health should not be their rival in practice, and that his opportunities of admonitory intercourse with sick families should not even be liable to abuse for the purposes of professional competition."

27. It is almost impossible to overrate the importance, or to question the practical wisdom, of the above recommendations. We cannot account for the fact that they have been utterly ignored in the Report and Memorandum issued by the Commission. The discouragement which this Commission has given to the separation of private practice from public employment is the more remarkable, inasmuch as sufficient evidence has been produced from English districts, as well as from continental states, to show that the union of the two occupations generally results in the failure of at least one of the objects of the practitioner, and often in the imperfect or perfunctory discharge of public duty.

28. No complete statement of the special duties of the *Medical Officer of Health*, properly so called, is to be found in the Report of the Sanitary Commission, although it contains a brief and imperfect summary of certain rudimentary duties, under four heads (vol. i, p. 34); and although the Memorandum (vol. ii, p. 353-4) refers particularly to certain forms of return, which the officer is to fill up and forward to the central office. In fact, no duties are here specified but those which concern his communications with the central department or its inspectors. After referring to the very important suggestions to be found in the evidence taken by the Commission itself; to the opinions of many eminent authorities at home and abroad given in reply to questions circulated by the State-Medicine Committee of the General Medical Council; and to the before-

mentioned Minutes of the General Board of Health; we confess our surprise that so limited and imperfect a view of the duties of this office should have been taken by the Commission.

29. The Commission proposes that it should be obligatory on every local authority to appoint at least one medical officer of health. The "urban" authorities will, therefore, have to appoint about a thousand such officers, who may or may not be poor-law medical officers. There must also, according to the plan of the Commission, be medical officers of health for every rural district, who are to be the poor-law medical officers. But as, according to the Earl of Devon, there are only 3,435\* district poor-law medical officers, even including the metropolis, it appears difficult to determine where the 4000 poor-law medical officers of health so frequently mentioned by the Commission, are to be found.

30. No definite arrangement for co-operative duty is suggested between the officers of "rural" and those of "urban" authorities, although the intermingling of their respective spheres of labour would, on the plan of the Commission, be of constant occurrence. Yet the Commission proposes (vol. i, p. 175) that in districts, such as the greater number of "urban", where two classes of medical officers may coexist in the same area, the relation of the health-officer and the destitution-officer should be arranged by the local health-authorities, with the approval of the central authority. Not to dwell on the vast accumulation of work which these arrangements would entail on the central authority, we object to so indefinite a scheme of medico-sanitary organisation, believing that in operation it would prove unsatisfactory and ineffective.

31. We note also that, both as regards the public and the poor-law medical officer, the proposals of the Commissioners are in the last degree unsatisfactory; for while—as if doubting the competency of the latter to discharge with thorough efficiency the varied and responsible duties of health-officers in chief—they suggest that "assistance and encouragement should be given to medical officers of health to study all sanitary questions" (vol. i, p. 35), they neither state in what form this encouragement is to be given, nor do they explain how, when, or where professional men, whose time and energies are absorbed in the necessary struggle for existence, are to apply themselves to the systematic study of preventive medicine. Again, in order to protect the health-officers in the "discharge of their duties without fear of personal loss", the Commission very properly recommends that they "should not be removable from office by any local authority, except with the sanction of the central authority" (vol. i, p. 35). But the Commission neither suggests any principle on which special remuneration for the sanitary work of these officers should be calculated, nor seems to recollect that the faithful discharge of public duties may involve the ruin of private practice; so that, unless the salary be large—in which case the scheme of the Commission will be enormously expensive—the protection against arbitrary removal will be of very trifling value. For, while the antagonism between public fidelity and success in practice is notorious and very real, the Commission assumes throughout that it does not exist, and fails to perceive that the allegiance of officers who depend mainly on private practice must be a divided one.

32. We must also enter an earnest protest against the idea that duties, requiring for their beneficial exercise much tact, prudence, matured judgment, and large experience, can, as a general rule, be safely entrusted to the inexperience of "young men entering on practice," by whom they would be discharged "only so long as they were acceptable, and then resigned to younger men, fresher from the schools." (Memorandum, vol. ii, p. 355.) These words seem to us to betray as utter a misconception of the nature and importance of the office as does the highly objectionable proposal (vol. i, p. 35, also p. 176, Resol. 22; and vol. ii, p. 354), that medical officers may themselves become nuisance-officers, or, as the latter are now improperly termed, "inspectors of nuisances". There are many reasons for relieving the medical officer, especially if he be a practitioner, from the onerous and damaging responsibility of searching out and reporting on nuisances. They ought to be referred to him by a subordinate officer specially appointed to discover them. The qualifications of this nuisance-officer should be defined either by the Act or by the central department. Regulations are also needed to promote the more efficient performance of the duties of this office. We see nothing of the kind suggested by the Commission.

33. Here we may remark that the Report of the Commission omits to recommend the enactment of any special and stringent regulations for the suppression of infectious diseases. All reference to measures by which the spread of this class of diseases may be arrested or controlled appears to be limited to a notice of certain provisions in the Sanitary Act, 1866, and to three lines in the next paragraph, page 48,

\* Copies of these documents may be had on application to our Honorary Secretaries.

† Attention is particularly requested to the striking observations made by the late lamented Dr. Symonds, during our interview with Ministers in May 1868. (See Appendix D.)

‡ We refer especially to the communication of Dr. Alfred Taylor, Mr. Michael, and Dr. Pappenheim of Westphalia (*Report of General Medical Council on State Medicine*, pp. 12, 29, 59, 61.)

\* A return which we have received from the office of the Poor-Law Board gives 3298 as the present number of district medical officers under the Poor-Law.

proposing that the central authority should "institute inquiries, and authorise the gratuitous dispensing of medicines and the speedy interment of the dead." Assuredly, if this destructive class of diseases is to be effectively encountered, some more complete and decisive enactments are required. Unless the regulations imposed are such as will meet epidemics at their first outbreak, so as to crush them in the bud, it will be found, as it has been, almost impossible to stay their course at any subsequent period. In relation to this subject, we beg to call attention to certain important amendments proposed by the Manchester and Salford Sanitary Association to Clause 26 of Mr. Goschen's Bill, which was equally deficient in this respect. (See Appendix E.)

34. While we perceive with satisfaction that the Commission (vol. i, pp. 61-177) recommends the registration of sickness, we doubt whether the method thereof should be wholly left, as proposed, to the Registrar-General, without insisting upon the necessity of considering in the first place the sanitary needs of the localities from which the returns are collected, and in which they ought to be promptly applied to local sanitary action. It is in regard of this function that a skilled and comparatively independent officer of health becomes indispensable; and the question yet to be solved is, what should be the maximum and minimum extent of area and population over which a chief health officer, acting also, according to Dr. Farr, as "Registration Medical Officer," could most efficiently and economically act. The proposal (Memorandum, pp. 353-4) to make the medical officer of the workhouse the official medium for collecting and transmitting returns of sickness is unsupported by reason or argument. For unless he is to revise and correct, which is not proposed, and for which he may not have the requisite qualifications, the Superintendent Registrar might perform quite as efficiently the merely clerical duty. A proper machinery for the local revision of mortuary and sickness returns, by a skilled and independent officer, would be provided by vesting the appointment of the chief health officers, debarred from private practice, in intermediate authorities; and to county justices, it may be observed, the legislature has committed the appointment of public analysts.

35. We propose that the right of separate appointment, by municipalities, of chief health officers, should be limited to large cities and towns, the authorities of which might be willing (as in Liverpool) to render their health adviser independent of private practice by a salary which shall, in the judgment of the central authority, suffice to secure the devotion of his entire time and thought to his public duties. All other towns would enjoy the advantage of superintendence by an officer of the same high class, appointed by a county or other intermediate authority. There would, moreover, be no necessity for the exceptional arrangements suggested by the Sanitary Commission (vol. i, p. 35; vol. ii, p. 354), which would leave certain very important scientific observations to be made only in those districts, the officers of which "desired, or were willing," to undertake them, a very imperfect and unsatisfactory method of public administration. *The system should be uniform throughout the country.*

36. While heartily approving of the proposal that "medical officers of health should be appointed subject to the veto, and should not be removed without the sanction of the central authority," we assert unhesitatingly that to compel all local boards to appoint their own officers, even subject to the above conditions, would be to force into action motives of personal interest and prejudice, of local favouritism, and of political-party ascendancy.

37. Nevertheless, while objecting, on the whole, to the project of health officers emanating from the Sanitary Commission, we strongly recommend, consistently with our previous suggestions, that, in the absence of an officer specially appointed for the purpose, the Poor-law medical officer should be authorised to act, and be suitably remunerated for acting, as an assistant or deputy health officer. Without indulging in any extravagant eulogy of this most useful and ill-requited body of men, we not only feel sure of their general fitness to perform all duties which it would be expedient to commit to them, but we are also convinced that their co-operation is absolutely essential to the proper working of any sanitary system; and their official recognition might enable the chief health officers to undertake wider districts than would otherwise be possible.

38. A fundamental reform in the administration of Poor-law medical relief would be essential to the well-working of a medico-sanitary organisation, and to a proper registration of sickness. The main provisions of the Irish Medical Charities Act ought to be introduced, and dispensaries established in every district, with such modifications of the system as may render it applicable to England. We strongly urge the adoption of a regulation under the above Act which prevents the appointment of any medical officer under the age of twenty-three years, and we also recommend that a special examination in certain matters of preventive and legal medicine be required, after a future date, to be

named in the new sanitary law, of all medical candidates for office of that age.

39. A precise inquiry would be necessary to determine the comparative cost of the two systems—the one proposed by the Sanitary Commission, the other now sketched in outline by ourselves.\* But it is obvious that, with a sufficient corps of chief health-officers, the inspecting staff in immediate connexion with the central authority need not materially, if at all, exceed the number now actually employed by the various central departments, which are to be consolidated, we hope, under one Minister of Health. Without a body of superior health-officers, either many necessary duties of superintendence and inspection (hardly noticed in the Report of the Commission) must remain unperformed, or an equally numerous body of district inspectors, under the central authority, must be appointed to execute them, at a great national cost.

40. Confining our remarks to the existing inspectorates, we heartily agree with the Sanitary Commission, that simplicity and economy alike demand their union under one chief, and their redistribution in circuits, analogous to the registration divisions, or the districts of Poor-law inspectors, which circuits might constitute the larger public health areas, except for any special purpose, as the control of river basins. In every such circuit it might be advisable, for efficient administration, that the central authority should act through three inspectors, with different qualifications—one legal, one engineering, and one medical or scientific. In the Memorandum (sec. 13), at least sixty-one general inspectors, now in office, are enumerated, and of these not more than fourteen or fifteen are medical. The latter would, therefore, be all required on a reformed system—eleven or twelve for circuits, and three or four for special investigations. The Commission seems not to require that there should be such completeness of organisation as is here suggested; yet without it we doubt whether any system of local government and public health administration can fulfil successfully its intended objects.

41. What seems to us the fatal objection to the scheme of sanitary administration proposed by the Commission, is that it presupposes the frequent intervention of the central authority and its officials, not only in the great movements of the sanitary system, but in many minute local details. It is to be worked—or at least regulated—from the centre, by inspectors who, not necessarily residing in the districts which they superintend, cannot know more of local circumstances and peculiarities than they can glean during brief and hasty visits. This mode of administration has the threefold disadvantage of being costly, of being inefficient, and of keeping the country in a state of perpetual tutelage. If, on the other hand, the inspectors, or rather chief officers of health, highly trained in all the departments of public medicine, were resident in their districts, each one of them would be a centre of instruction whence sound and enlightened views on all sanitary matters would emanate, so as gradually to enlighten the public mind, stimulate local action, and reduce to a minimum the need of interference by the central authority. The Commission, however, would make that the exception, which we maintain ought to be the rule, and appears to be so scrupulous of permitting any competition by "men of higher attainments and qualifications" as actually to recommend (Memorandum, vol. ii, p. 354) that "such exceptional arrangements should be made under the direct sanction of the public health minister." Should these views unhappily be adopted, we have before us the dreary prospect of a dead level of official respectability and routine, under the patronage and protection of the central authority.

42. With respect to the proposed central authority, we thoroughly appreciate the importance of providing that every existing department, including several under the Home Office, the Privy Council, the Board of Trade, and the Poor-law Board, besides the General Register Office, the Lunacy Commissioners, and the General Medical Council, should be severally and individually represented in a Supreme Council of Health, to be presided over by the one minister.

43. We deem it unnecessary to comment further on this very important Report, by way of either support or criticism, although there are other particulars on which we might dilate. We conclude by repeating our desire for a careful personal inquiry in the various localities throughout the country, before legislating permanently on the details of sanitary administration.

## APPENDIX.

A.—Extract from "General Report on the Sanitary Condition of the Labouring Population," 1842, p. 355.—"Whatever administrative arrangements sustain narrow districts and narrow practice, sustain, at a great public expense, barriers against the extension of knowledge by which the public would benefit, and arrangements by which such districts or confined practice are newly created will aggravate existing evils."

B.—Extracts from Letters from Dr. Strange to Dr. Ramsey, February 26th

\* See also "Memorial" of Joint Committee to Her Majesty's Ministers, May 1868, paragraph 5.

and March 15th, 1871.—(1) "In my old paper (1846) I spoke of a hundred and sixty officers, or about four for each county, as the quantum required. But I am one of those who, like yourself, have reduced our estimate of the number of district-officers that would be necessary."

"For instance, I think that for such a county as this (Worcestershire), excepting the Dudley district,\* one officer could do the work if he had a proper office, clerks, etc., provided for him. . . . My fear is that every town like this (Worcester), Bath, Cheltenham, etc., will be allowed to appoint an officer of its own. This would be fatal to the well-working of the scheme."

"I would therefore advocate arrangements on a large scale, because, if the districts were found to be too large, it would be easier to divide them hereafter than to alter the petty arrangements made by each local authority."

"(2) I think that about a hundred officers, independently of the metropolis, would be required. Counties of not more than two hundred and fifty thousand population might perhaps be superintended by one officer, provided there was no great town in them. Where the principal town is large enough to pay an officer of its own, the rest of the county, in many cases, might be managed by one officer, although others doubtless would require more. Towns containing less than sixty thousand inhabitants, if appointing independently their own officer, would be sure to pay him badly, or perhaps distribute the work among the Poor-law medical officers. It is to guard against this that we must enlighten the public mind."

C.—*Extract from Letter from Dr. W. Budd, F.R.S., to Dr. Rumsey, May 8th, 1870.*—"On main points we are quite agreed as to what should be the character of the new sanitary organisation. I am strenuous, in the first place, for a county administration; not only because this offers the only safeguard against metropolitan absolutism, both in theory and practice, but because the elements of a county organisation already exist, and have already been largely and successfully employed in the suppression of disease—to wit, in the sheep's small-pox and the cattle-plague. In legislating on such matters, it is always best to go, as far as possible, on the old lines."

"As regards the appointment of the Poor-law officers, on condition of their acting only as deputies to the chief, I have no objection to the proposal. The only difficulty, I fear, would be as to the funds required to remunerate them for their additional labour. . . . I acknowledge that in naming from £500 to £800 (for the chief officers) I pitched the salaries too low. I was not quite prepared for the question at the time, and was no doubt impressed by what seemed to me to be the master impulse of the whole Commission—the dread of adding to expense. At the same time, I think that some error in over-estimating the number of superior officers necessary for the work. In exactly the same measure in which you increase the number of these functionaries, you tend to diminish the salary of each. In these matters it is important to go on principle, and I hold this to be a principle which lies beyond dispute, that it is incomparably better for the success of the work to have a few well-paid and very able men, than to have a number of inferior capacity at a lower salary. . . . Having thought over the matter as regards the county of Devon, since I gave evidence, I am prepared to stand by my suggestion that three officers—one for each Parliamentary division (Evid. 9,319) or Coroner's division (9,320) would be sufficient."

"This should always be borne in mind—1, that the sum to be distributed among the superior officers in each county will be a stated and limited sum; and 2, that the money, being partly for Imperial and partly for local purposes, will most probably be drawn in part from the rates, and in part from the Consolidated Fund."

D.—*Extract from Report of Deputation. Dr. Symonds's Speech, May, 1868.*—"Dr. Symonds urged that the Government should encourage the creation of a new order of medical men who would give their undivided attention to sanitary matters, and to questions of medical jurisprudence. He then proceeded to say that the medical profession had been growing more and more anomalous in sanitary matters, and so great an amount of work had come to be imposed upon the profession, that it was getting to be more than the shoulders of medical men could bear. Medical men were chiefly educated for the care of the sick; and, in the practice of professional duties over some years, a great deal of the knowledge which they primarily possessed would be found to have slipped away from their memories when they were suddenly examined upon some particular point requiring minute investigation. Now, the medical man, when called upon to give evidence in a court of law, had to do so on three different heads. He had to give evidence such as an ordinary witness would on points which would be within general observation; then he had to give evidence of matters which had come within his knowledge as a professional man; then he was called upon to speak as to circumstances of which he was supposed to possess a knowledge by an acquaintance with chemistry and natural science. But it must be stated that a man might have possessed a great amount of knowledge of chemistry and natural science at an earlier time of his life without being able to prove his knowledge in a law-court; and he might be a most able practitioner, yet, when called upon to discharge the duties of a medical jurist, might show great shortcomings. Then medical men were differently qualified in different parts of the country, and while some were educated well, others were educated ill. Surely, under these circumstances, it was not right that men should have the administration of the sanitary laws with only a general professional knowledge. This was a most important point, for the people had the right to have the best and most efficient officers to be obtained; what was required in Lincolnshire was demanded in Lancashire, and it was not right that there should be any difference in the qualification of the men who were to administer these important laws either in the one place or the other. It seemed to those who attended there, that a new order of medical men should be called into existence, upon whom should devolve the consideration of all those questions, who should be able to advise and instruct in all matters of sanitary science, and who would be able to answer off-hand all points which might easily have passed from the mind of general practitioners. Such a new order of medical men, by their influence on the public, by the education of the public in the laws of health, would do a vast amount of good among all classes of Her Majesty's subjects. The deputation asked that there should be a Royal Commission to consider these most important matters, and those present were sure that research would show the necessity for the appointment of such men as officers of health, who would give confidence to all."

E.—*Amendments Proposed by the Manchester and Salford Sanitary Association in Clause 26 of the dropped Bill on "Rating and Local Government". Obligations of Sanitary Authorities, of Persons under their jurisdiction, and of Medical Practitioners with respect to Disinfection and the Disposal of Dead Bodies.*—Every sanitary authority shall, by constructing, purchasing, or hiring,

\* The population of the county of Worcester proper is now 338,848, on an area of 472,165 acres—more by far, in my opinion, than could be properly managed by one officer, if he were to superintend the registration of births, deaths, and diseases. Perhaps two officers might suffice, and be appointed, for instance, one for each parliamentary division.—H. W. R.

or contracting for the use of the places and things hereinafter mentioned, provide its district with proper places furnished with proper apparatus for disinfection of clothes and other articles, with a proper carriage for the conveyance of infected persons or of persons suspected of being infected, and with hospitals to which persons incapable of taking proper precautions against infection and affected or suspected of being affected with infectious diseases may be removed.

The Local Government Board may, on the application of any ratepayer within the area subject to the jurisdiction of a sanitary authority, require such sanitary authority to provide a proper place or proper places for the reception of dead bodies accordingly.

The places and things provided by any sanitary authority, or union of sanitary authorities, in pursuance of the foregoing requisitions of this section, shall be subject to the approval of the Local Government Board.

The occupier, or person in charge, of a house or tenement in which a person is ill of fever, or any infectious disease, shall give immediate notice thereof to the sanitary authority, or to some officer of the sanitary authority, having jurisdiction over the area within which such house or tenement is situated, and such sanitary authority shall furnish such occupier, or person in charge, with printed recommendations, approved of by the Local Government Board, respecting the disinfection of clothing and other articles, and precautions to prevent the spread of infectious diseases. Such occupier, or person in charge, shall, from the date of such notice, obtain and send to the said sanitary authority at intervals not exceeding ten days, the certificate of a legally qualified medical practitioner, that proper precautions have been taken to prevent the spread of such infectious disease to other persons, until the said occupier, or person in charge, obtain and send to the said sanitary authority the certificate of a legally qualified medical practitioner, that no person in such house or tenement is ill of fever or any other infectious disease, and that such house or tenement, or such parts of it as require to be disinfected, and the clothes and other articles in and about it requiring disinfection, have been satisfactorily cleansed and disinfected.

Any medical practitioner, attending a person who is ill of fever or any other infectious disease, shall give immediate notice, in the manner and form hereinafter described in schedule—to this Act, of the infectious character of such disease, to the occupier or person in charge of the house or tenement in which such person who is ill of an infectious disease is, and also to the sanitary authority having jurisdiction over the area within which such house or tenement is situated, for which such medical practitioner shall be awarded by the said sanitary authority such remuneration as shall be approved of by the Local Government Board.

The occupier or person in charge of any house or tenement in which an inmate is dead, and which is situated within the area subject to the jurisdiction of a sanitary authority which has provided a place or places for the reception of dead bodies, shall either keep and retain the dead body of such inmate in a room in which persons do not live or sleep, or shall give immediate notice of the death of such inmate to such sanitary authority, and if such inmate has died of an infectious disease, or if the dead body of such inmate is in such a state as to endanger the health of the inmates of the house or room in which it is retained, such sanitary authority may, on the certificate of its officer of health, or of a legally qualified medical practitioner, make any order or orders which a justice may now make, on the certificate of a legally qualified medical practitioner, respecting any dead body of a person who has died of an infectious disease or any dead body which is in such a state as to endanger the health of the inmates of the house or room in which it is retained.

Any person failing to give any notice required by this section shall be liable to a penalty of any sum not exceeding £20, and if any owner or occupier of a house or tenement in which a person is ill of fever or any other infectious disease fail to send to the sanitary authority having jurisdiction over the area within which such house or tenement is situated, any certificate required by this section, such authority shall, on the certificate of its officer of health, or of any legally qualified medical practitioner, exercise the powers and do the things which a nuisance authority may now exercise and do on the certificate of a legally qualified medical practitioner.

The guardians of any union, or the guardians of any two or more unions, and any sanitary authority, and any two or more sanitary authorities, may, with the approval of the Local Government Board, make mutual arrangements as to carrying into effect the foregoing provisions and any expenses incurred by such authorities in pursuance of such arrangement shall be deemed to be expenses incurred by them in the performance of their duties.

If any sanitary authority fails to comply with the foregoing requisitions of this section, or makes default in the performance of any duty which it is bound to perform in pursuance of the forty-ninth section of the Sanitary Act, 1866, as amended by this Act, the Local Government Board may, on the application of any ratepayer within the area, subject to the jurisdiction of the defaulting authority, or of any person aggrieved by such default, require the sanitary authority to remedy the default complained of, and if it fails to do so within a specified period, may suspend all the powers of such authority in its character of sanitary authority and delegate to the County Board of the County in which the district, or the greater part in area of the district, is situate, or to any person or body of persons, the powers of such sanitary authority until the default is remedied.

Any body of persons to whom such powers may be delegated shall, if they are not a body corporate, be (incorporated) a body corporate for the purposes of their establishment.

The form of this notice should be such that medical men would be obliged to state the names of the infectious diseases attended by them, as well as their infectious character.

Every sanitary authority should be required to make yearly returns to the Local Government Board as to the names of the diseases of which it has notice, their duration, etc. This would provide machinery for the registration of infectious diseases in private practice. These points were not before the General Committee of the Manchester and Salford Sanitary Association.

MUSHROOM POISONING.—A sad case is reported from Cornwall, which should serve as a caution to gatherers and eaters of mushrooms. At Flushing, near Falmouth, on Tuesday last, a boy and girl, aged respectively six and twelve years, died through eating the poisonous fungus known as toadstool, in mistake for mushrooms. The mother, Mrs. Rusden, is also in a precarious condition, having partaken of the same gathering, and two or three fowls were killed. A woman in Truro had a narrow escape a few days ago, having bought a lot of toadstools, which were thought to be mushrooms, of a girl who had a large basket full for sale.

"President of Council shall direct to be called."—Rule 14. Between "shall" and "be recommended," to insert "express his desire in writing, and shall be."—Rule 15. To add "Members may be admitted on and after July 1st in each year, and the subscription for such part of a year shall be half a guinea." To erase the words after "such member" in eighth line, and to substitute "as long as his subscriptions remain unpaid, provided due notice shall have been given of such withholding."—Rule 16. To erase the words after "from his" in fourth line, and to substitute "liabilities to the Association."—Rule 24. In tenth line, to insert "a copy of the laws" between "Association" and "and."

These, after a few suggestions regarding verbal alterations, were adopted.

Dr. WADE, of Birmingham, moved a resolution that in Law 8, paragraph No. 3, of the duties of Council, the "25" be altered to "10," and to omit the words and "one Secretary from each Branch." He said the objection he made to the secretaries sitting on the Council as representing, was a practical as well as a theoretical one. The branches should be represented directly, instead of indirectly, on the Committee of Council, which was the real managing body of the Association. He heard that local branch secretaries were very hard-worked, and if so, they had other duties to attend to beside assembling at the Council meetings, and besides they got no honour from the appointment to serve. He quoted the returns of attendances of local secretaries, showing that not more than one and a half per cent. of them attended at the Council meetings, and he hoped that if his motion were not carried, the members of the Association would think over his proposal and its bearings.

Dr. FELCE seconded the motion, and it was supported by Dr. DAVEY of Bristol.

Mr. HUSBAND said it was requisite that those who attended the Committee of Council should know the work of the Association, and he was sure he would have the cordial agreement of all who knew the work and how it was carried on, when he said that the Committee of Council had received the most important services from gentlemen who had come there as secretaries of branches. [*Hear, hear.*] He might be called an "old Tory" in thus objecting to a change of this character, but he would point out that the Council was chosen by the members of the Association, and the addition of the local secretaries as representing the branches made as good a working mixture as the Association could have. This had worked well, and he should be sorry if the Association now ruled that these secretaries should no longer be allowed to represent their branches.

Dr. STEELE said his constituents would feel deprived of a great privilege if the secretaries of local branches were not to represent those Branches as at present, for this was the only way by which members had effectual and certain representation on the Committee of Council; and if it were struck out, the Lancashire Branch might not have a single representative on the Committee of Council. He hoped that some attention would be given to the question of paying the expenses of those secretaries who attended by the Branches whom they represented. This was done by some Branches, and if it were done by all there would be a larger attendance of the secretaries, who were men eminently qualified to know the feelings and views of their brother members in their Branches. He hoped the motion would be negatived. [*Hear, hear.*]

Dr. SIBSON said he quite agreed with Mr. Husband that a great advantage was derived from the presence of the Branch Secretaries; still, the question of representation might be considered by the Council. As the Association had doubled its members since the last numbers of representatives on the Council were fixed, it would be just and wise to consider what proportion the number of representatives bore to the now enlarged number of members. [*Hear, hear.*]

Dr. WADE said he would undertake, with the consent of his seconder, to withdraw the motion if the Council would undertake to meet the whole question. He had no objection to the names of gentlemen being on the Council when they attended, but he objected to the names remaining if the representatives did not attend.

Mr. HECKSTALL SMITH held that all Branch Committees ought to consider whether they would pay their secretaries' expenses for attending the Council Meetings.

Dr. BRYAN said this motion evidenced a thorough want of consideration for the feelings of Branch Secretaries. Even if the secretaries did not attend, the right of attending was at least a compliment to them for their labours. It would entail a great expense upon a member living in Cornwall or Wales to attend in Birmingham or London, just for a Council meeting; but this was a right which local secretaries should have for their labour. [*Hear.*]

The motion was then withdrawn.

Dr. STEELE (Liverpool) then proposed the motion of which notice was given:

"That every associate, who is a member of the Council, and desirous of a seat on the Committee of Council, shall send to the General Secretary, not later than three months prior to the Annual Meeting of the Association, a declaration signed by himself, and in the following terms: 'I, A. B., of C., member of the British Medical Association, hereby declare that I am a candidate for a seat on the Committee of Council of the said Association. (Signed)———.' Together with a nomination-paper signed by six members of the Association, in the following terms: 'We, the undersigned, members of the British Medical Association, certify that A. B., of C., is a fit and proper person to be a member of the Committee of Council of the said Association.' The names of the eligible candidates, with the names of the six associates by whom they shall have been respectively nominated, shall be published in the BRITISH MEDICAL JOURNAL not later than three months prior to the Annual Meeting of the Association."

He said he had no objection to reduce the number of those who were to certify to the fitness of the candidates. The purpose of the proposed resolution was, he said, obvious, for at present the mode of election was as unsatisfactory as it could be, for it always came on late in the day. [*No, no; always early.*] Well, let it come on when it might [*laughter*], the members were called upon at once to elect without previous opportunity of considering who were likely to serve well, or of knowing those who were to be proposed. Pieces of papers were handed about for persons to propose others; and it had happened that the persons elected had afterwards said they could not serve. But it was not so much against these practices that his resolution was directed, but it was to meet the objections to the present plan, which was considered by many to make the Committee of Council a mere family party. He had it from some that no one could expect to be elected to the Committee of Council who did not belong to a certain clique. It might be that this was not correct; and if it was not, it was quite as necessary to alter a condition of things which created dissatisfaction, and gave rise to such suspicions. If this motion were adopted, the Association would be enabled to select the best men, and who would have pledged themselves to do their duty.

Mr. HUSBAND regretted anything should come before the meeting from Dr. Steele which he himself could not support. He said that no gentleman would, he would venture to say, sign such a declaration as this motion set out, and have it published in the JOURNAL for two or three months before the election. Moreover, the Branch Meetings for election of the Councillors from whom the Committee of Council were elected, did not take place till within a few weeks—sometimes a week or ten days—of the Annual General Meeting. Altogether he held the motion to be impracticable, and said the present mode of representation had its great advantages. Every member of the Council was elected in his own part of the kingdom by his colleagues who knew him well, and the result was that the Association had a Council of good men ready to do the Association excellent service. But if this motion were carried, he for one would not sign such a declaration. [*Hear.*]

Mr. HECKSTALL SMITH denied that there was any foundation for the hint that the Committee of Council was a family party.

Dr. STEELE, in reply, said he thought this motion might have been agreed to; and if it were not, he should persevere in bringing forward the subject. He held that the Committee of Council was not a fair representation of the general body; and he did not think his motion was so impracticable as it had been declared.

The motion was then negatived, nine hands only being held up for it. Mr. NICHOLSON, of Hull, then proposed to insert "2" for "3" in Law 16, line 2, having reference to the time a member's name shall remain on the books after his subscription shall remain unpaid.

This was seconded and agreed to unanimously.

Mr. HUSBAND then moved—"That the Committee of Council be empowered to appoint a Secretary *ad interim*."

Mr. A. BAKER seconded this motion, and added to it that the Committee of Council should also have power to make rules to govern the secretaryship.

This was carried *nem. con.*

Mr. SOUTHAM moved that the two auditors, to whom the Association were before indebted, Dr. Fox and Mr. Church, should be re-elected auditors.

Dr. H. HARRIS seconded the motion, which was also adopted, with the addition, on the suggestion of Mr. Husband, that the auditors should have the power to call in a professional auditor with the assent of the Treasurer.

The meeting then concluded, with thanks to the President, shortly before midnight.

## WEDNESDAY, AUGUST 9th.

The Second General Meeting was held in the Devonport Town Hall on Wednesday, which—pictures included—has recently undergone renovation, and looks uncommonly well. There was a very full muster of the members of the Association, the special attraction being the Address in Medicine of Dr. George Johnson. Mr. WHIPPLE, the President, having taken the Chair, the Corporation of Devonport, headed by the Mayor (Mr. J. May), in his robe and chain, and the Town Clerk (Mr. Woolcombe) presented an address.

HIS WORSHIP said he begged to be allowed in the name of the town councillors and burgesses of the borough to welcome the Medical Association to Devonport. He hailed their advent among them with great satisfaction. He looked upon the object of their Association as primarily the advancement of the art and science of medicine, and as such the amelioration of the condition of society at large. He recognised, also, in those annual gatherings, a desire, and a very laudable desire, for recreation after the hard work that daily practice entailed on most of them, and he hoped that their visits to the numerous public establishments, as well as the beauty of the surrounding scenery, would enable them to enjoy their hard-earned holiday. [Applause.]

The Town Clerk then read the address as follows:—"Gentlemen,—We, the mayor, aldermen, and burgesses of the borough of Devonport, have great pleasure in welcoming the numerous and distinguished members of the medical profession who have honoured us with a visit at the present time. The united influence of your Association, embracing the most eminent and distinguished members of the profession, has already led to results of the greatest value. The discharge of your functions, always freely exercised by individuals for the benefit of rich and poor, assumes a vastly increased importance by that personal communion which, leading to the interchange of knowledge acquired by long and patient research, not only adds to the honour of your profession, but still more advances the welfare of mankind. The researches of your body have already demonstrated the vast amount of mortality due to preventable causes which, now perfectly obvious, have hitherto been ignored. On us, as a civil corporation, is now cast the heavy responsibility of giving effect to those searching measures which are within our power, and of promoting those further improvements, the necessity of which you have made apparent. We shall rejoice if we are able to co-operate with you in promoting the further remedial legislation so urgently required for the public health. Your body may well claim to be sanitary pioneers, and we trust we shall not fail in any efforts which may be required to facilitate your progress." [Applause.]

THE PRESIDENT, in reply, said it was with no little feeling of gratification that he returned thanks for himself, and the Association by which he was surrounded, for the very flattering reception that had been accorded to them. That was the second address of the sort, he believed, that had been presented. He was sure that he only reiterated the feelings of every one of the Associates when he expressed the deep sense of the high compliment that had been paid them. [Applause.]

Mr. T. WATKIN WILLIAMS (Secretary) stated that the Council had decided to recommend that Birmingham should be the place of meeting in 1872, and Mr. Alfred Baker President.

Mr. UNDERHILL, of Birmingham, begged to request in the most earnest way that the Association should hold their meeting in that town next year. He need not say much in favour. The geographical position of the town was of great importance; and though it could not offer perhaps the great natural advantages which that beautiful locality could, there were nevertheless attractions about it in relation to manufacture and the rapid advancement of science that would recommend it to their notice. He could offer them a most hearty welcome. With regard to the suggestion that Mr. Alfred Baker should be elected President, he might say that that gentleman had been elected unanimously by the Branch, and he could say to those who did not know him so well as he did, that Mr. Baker's social qualities were of a very high order. [Applause.]

Dr. CHAPWICK (Leeds) thought Birmingham very suitable for a place of meeting, and moved that the recommendation should be adopted.

The Rev. Dr. HAMBERG (Dublin) in seconding the resolution, referred to his personal knowledge of the hospitality and good qualities of Birmingham. An interesting feature of medical inquiry, alluded to in the address, was the great interest by the Association, not so much in cure as in the prevention of disease. They in England were naturally alarmed at the dread approach of cholera. It was observable, and was a phenomena well worthy of attention, that Birmingham had been singularly free from that disease. It would be for the friends there to tell the Association the reason of this.

The motion was carried by acclamation.

Mr. ALFRED BAKER, who was heartily received, in thanking the

meeting for the honour they had conferred on him, said he hoped they would find any defect of his more than made up by the services of those gentlemen who would be associated with him. The whole inhabitants of the town would join in giving a welcome, and he had every confidence that a successful meeting would be held in his native town. In such a meeting many would have the gratification of renewing old friendships and making new ones. [Applause.]

Mr. HUSBAND called attention to the fact that it would be impossible to appoint a new secretary for some time. It was proposed by the Council, therefore, that Mr. Williams should be asked to continue to hold office for six months until his successor should be appointed; they likewise suggested that he should receive for that period, in consideration of the additional labour that would be involved, £200 instead of £150.

The proposal was adopted, Dr. Falconer, Dr. Stewart, Mr. Gamgee, and others, speaking in its favour.

Mr. WILLIAMS, in reply, said he should be most happy to do all that he could to initiate his successor into his duties. [Applause.]

A subcommittee was then appointed to define what those duties should be.

Dr. GEORGE JOHNSON then delivered the Address in Medicine, which was listened to throughout with the greatest attention by the large body assembled in the fine hall.

When Dr. Johnson had finished his address there were loud and long continued cheers.

Dr. A. P. STEWART immediately arose to propose a vote of thanks to Dr. Johnson, who, he said, had eloquently addressed them on many points of special interest and importance at this time, and what they had heard would be carried to different parts of the kingdom to fructify in the minds of the large professional audience. The address they had just heard formed a worthy sequel to the addresses of such men as Sir William Jenner, and the other high authorities who had gone before.

A MEMBER in the body of the meeting seconded the motion, and said he hoped the address would spur medical men to investigate the phenomena of disease, and to do more than stand idly by when they came to a bedside where they found a difficult case.

The vote was carried with acclamation, and the meeting separated.

## THURSDAY, AUGUST 10th.

The Third General Meeting was held in the Royal Hotel, Plymouth; the President in the Chair.

Dr. EDWARD WATERS read the Report of the Reform Committee. This was as follows.

The Reform Committee of the British Medical Association, appointed at the annual meeting at Newcastle in August 1870, have to report that they have been unable to effect a settlement of the question of Medical Reform during the past session; but, as stated in the Report of Council, "the Committee are of opinion that the field has been cleared for action; and arrangements have been made which, it is hoped, will conduce to a settlement of the long vexed question before the next annual meeting of the Association."

The withdrawal of the Bill of the Government in 1870, in consequence chiefly of the refusal of the Direct Representation Committee of the Association to accept any amendment of the Medical Acts which did not embody direct representation of the profession in the General Medical Council, constituted the Association the champion of medical reform, and threw on it the responsibility of undertaking medical legislation, with a view to the realisation of the oft expressed will of the Association. The Reform Committee appointed to carry out this object met in Birmingham on December 27th. Dr. Waters was appointed chairman; and a Subcommittee, consisting of Dr. Waters, the President, the President of Council, Dr. Falconer, Dr. Stewart, Mr. Michael, and the General Secretary, was appointed, with power to act. It was resolved to draft a Bill based on the Government Bill of last session, but embodying the principles contended for by the Association. Before coming to this decision, the Committee, in a spirit of loyalty to the profession and to the public, carefully considered the provisions of all other schemes of reform which had been promulgated. In the hope that the Government might be influenced by the numerous petitions for direct representation on the Medical Council which had flooded the House of Commons, not only from members of the Association, but from thousands of the registered practitioners of the United Kingdom, it was deemed advisable to test the opinion of the Government on the clauses of the proposed Bill of the Association, and to endeavour to obtain from the Government the adoption or approval of the demands of the Association. The Reform Committee sought, therefore, an interview with the Lord-President of the Privy Council, as the author

of the Bill of last session. The request was granted; but, in consequence of the enforced absence of his lordship on a mission to the United States, the Committee were on the 14th of February received by the Right Hon. W. E. Forster, Vice-President of the Privy Council. Mr. Forster was accompanied by Mr. Simon, the Medical Officer of the Privy Council. The Committee submitted to the Vice-President the continued existence in the profession of a determination to accept no measure of medical reform which did not concede direct representation, compulsory registration, improved examinations, and the annulling of honorary degrees in medicine by the reinstatement of the withdrawn eighteenth clause. The fact that the medical authorities in Ireland had recently decided in favour of direct representation in the Medical Council by a majority of eleven to one was also laid before him. The Vice-President stated, in reply, that the Government would not undertake the question of medical reform this year, owing to the great pressure of other public business; but would give its careful consideration to such a measure as the Committee had indicated, when brought forward.

On Tuesday, February 28th, the Reform Committee held a meeting in London. Mr. Dalrymple, M.P., who had engaged to press forward the amendments of the Association in favour of direct representation, if the Government Bill of last session had passed the second reading in the House of Commons, and who has always aided the previous and present Committees by his advice and co-operation, as well as Mr. Hart, the editor of our JOURNAL, were present. It was unanimously agreed to ask the Right Hon. Mr. Headlam, M.P., to whom the Medical Act of 1858 is virtually due, he having, with the support of Sir Charles Hastings and the Association, triumphantly carried, contrary to general expectation, on July 1st, 1857, the second reading of his Bill by a majority of 147, to take charge, in conjunction with Mr. Dalrymple, of the Bill of the Association. A meeting, attended by several members of Parliament, was held in the House of Commons the same evening; and Mr. Headlam consented to take charge of the Bill of the Association. The same evening, Mr. Headlam gave notice in the House of his intention to bring in the Bill. On the following day (March 1st), Dr. Stewart and the Chairman, authorised by the Committee, went through the Bill of the Association, clause by clause, with Mr. Headlam, and, in doing so, strictly adhered to the principles enunciated and repeatedly endorsed at the general meetings of the Association.

All the details of the Bill having been thus settled, Dr. Lush, M.P., and Mr. Brady, M.P., gave notice of two other and separate Bills, differing widely from each other: one, the "*Lancet* Bill", promoted by the staff of that journal, introduced by Dr. Lush; the second, the Bill of the Irish College of Surgeons, introduced by Mr. Brady. Under these circumstances, Mr. Headlam and Mr. Dalrymple deemed it unwise to proceed with the Bill of the Association. They were strongly of opinion that the introduction of three Bills—rival schemes, as they would be described—would damage the profession in the House of Commons. They were convinced that both the measures referred to were impracticable; as the Vice-President of the Privy Council had, indeed, declared with regard to the *Lancet* Bill, to the deputation which waited on him in support of it; and that it would not be wise to risk the measure of the Association by attempting to press it forward at the same time. The Reform Committee yielded to the experience and advice of Mr. Headlam; and they have in consequence deferred pressing the Bill of the Association during the past session. They did not, however, attempt any opposition to the other Bills, but, on the contrary, left the course free for the supporters of them. The result has been, that both Bills were withdrawn on June 14th, and that for the present session there is an end of medical reform.

Your Committee have to report that, though the present session has proved barren of medical legislation, their knowledge and experience of parliamentary tactics have been materially increased. The power of the Association has been greatly strengthened by its steady and continued adhesion to the principles it has so repeatedly affirmed; and the delay of twelve months has only made more clear that no measure of medical reform will ever be accepted by the profession which does not give a full and adequate representation of the whole profession in the General Medical Council.

In conclusion, the Committee have to repeat that the ground has been cleared for action. The peaceful termination of the momentous events which have convulsed Europe since our last anniversary gives the Association a better chance of being listened to by the Legislature; and the communications which the Committee have had with several gentlemen interested in the question, and others, lead them to anticipate in the next session of Parliament more definite results than have hitherto been attained.

EDWARD WATERS,  
Chairman of the Reform Committee.

Dr. BRYAN moved that the Report be adopted, and the Committee reappointed.

Mr. NICHOLSON seconded the motion, which was carried unanimously.

Dr. G. H. PHILIPSON then read the Report of the Committee on the Observation and Registration of Disease, which was as follows.

The past year has been full of promise of the ultimate success of the efforts of this Association to bring about a national registration of disease. At the general meeting, held at Newcastle-on-Tyne, on August 12th, 1870, it was resolved—"That a deputation from the Association should seek an interview with the President of the Poor-law Board, to represent to him the views of the Association with respect to the registration of disease, and that Dr. Rumsey, Dr. Sibson, Dr. A. P. Stewart, Dr. Morgan, and Dr. Ransome be requested to form the deputation."

In accordance with this resolution, the above named gentlemen waited upon Mr. Göschén, in conjunction with a deputation on the same subject from the Poor-law Medical Association, and several other gentlemen interested in the question. After a careful inquiry into the views of the deputation, Mr. Göschén said that the arguments in favour of the registration of disease were very clear and strong, and that every one must accept them. The chief points to be considered were by what machinery it could be carried out, how rapidly, and at what cost. He thought, however, that the question was one for the Government, and not for his department, and he remarked that it would be undesirable to go into the matter until the report of the Royal Sanitary Commission had been considered by the Government.

The report of this Commission appeared in the spring of the present year, and contained very important and conclusive arguments for a registration of disease, apparently in every respect identical with that proposed by this Association. We append an extract from this report, from which it will be seen that the Commissioners were fully impressed with the importance of the subject, and with the necessity both of obtaining speedy returns of new cases of diseases occurring amongst large bodies of the population, and of making these returns immediately available for the suppression of epidemic disease. It does not appear, however, from the recommendation of the Commission, that any definite plan for obtaining these objects is put forth, nor any arrangement made for transmitting the records through a local officer of health. Your Committee recommend, therefore, that a memorial be addressed to Her Majesty's Government, praying that in any measure of sanitary reform this most valuable aid to the suppression of disease should be fully provided for, and that arrangements should be made by which health officers could make immediate use of the returns of disease before they are transmitted to the central offices of the Government.

Your Committee regret that they have to announce the discontinuance of the returns made for the last four years by the Northumberland and Durham Medical Society. Although those made at Manchester and Salford, St. Marylebone, and Birmingham still continue, the fact that this influential body is unable to carry on the undertaking is only another proof of the need of a truly national registration of sickness.

Mr. DYKE (Merthyr Tydfil) said he had great pleasure in moving the following resolution on this Report.

"That this Association, whilst it gratefully acknowledges the favourable reception accorded to its views on the subject of the registration of disease, both by the Government and the Royal Sanitary Commission, desires to urge the importance of making the returns accurate, and immediately so available in the localities from which they are procured; and therefore points out the need of a superior health-officer in every area of sufficient size, by whom, amongst other duties, the returns could be collected, and immediately applied to the wants of the district. Also that the Committee on the Observation and Registration of Disease be reappointed."

Dr. WILKINSON said the subject was a most important one, and he had great pleasure in seconding the motion. This was carried unanimously.

Dr. A. P. STEWART then proceeded to read the Draft Report of the Joint Committee of the British Medical and Social Science Associations. Before, however, he had finished, the time for Mr. Lister's address had arrived; and Mr. Lister, who at the moment entered the room, was warmly cheered by the large audience which had met to hear him. The further reading of the Committee's Report was postponed until after the Address in Surgery; and Mr. Lister was again greeted with hearty cheers when he presented himself to give this address, part of which was extemporaneous.

When Professor Lister had finished speaking, he distributed small portions of the material he used in his treatment.

Mr. MAY, the Mayor of Devonport, then rose to propose the vote of thanks to the Professor, a resolution, he said, to which all would agree with pleasure. The marked and sustained attention which they had all

shown to this long lecture, the delivery of which must have been a great strain upon the worthy Professor, proved that it was far too short for them, though it had occupied two hours. [*Cheers.*] Those living on the south of the Tweed were at all times ready to acknowledge that the school of Edinburgh held a proud position, and had given many bright names to the science; and the meeting of the Association, having heard Professor Lister, would readily believe that the mantle of those bright and worthy men who had preceded him had fallen upon him. [*Cheers.*] To him it was given to maintain the honour and the great name of his school, and he (Dr. May) proposed that the cordial thanks of the meeting be given to the Professor for his valuable address.

Mr. MACNAMARA seconded the motion, and said the Professor had charmed the ears of all who had heard him, and enlisted their sympathies. The Professor had made some observations reflecting upon the reasoning powers of some of his professional brethren, as shown in their opposition to his system; but even this might be turned to compliment by the Professor, for all knew that error was rapid in its progress and truth was slow. [*Cheers.*] There was one germ which prevailed throughout the theory the Professor had propounded, a germ which the Professor must be proud of, for it was the germ of truth. [*Cheers.*]

The vote was carried with acclamation, and the meeting separated.

#### FRIDAY, AUGUST 11th.

The Fourth and Last General Meeting was held on Friday afternoon in the Assembly Rooms at the Royal Hotel, Plymouth; the President, Mr. WHIPPLE, in the Chair.

Dr. A. P. STEWART proceeded to finish the reading of the Report of the Joint Committee of the Social Science and British Medical Associations. He complained that the Royal Commissioners, in their Report lately upon some of the points dealt with in the Joint Committees' reference, had entirely ignored the recommendations of the Committee.

Mr. GEORGE HASTINGS moved the adoption of the Report, which he said was a valuable contribution on the subjects concerning which it treated. The only subject upon which he would express any regret was, that he had not seen at this meeting a gentleman who had contributed greatly to the value of the Report—Dr. Rumsey of Cheltenham—and it was a great calamity that that gentleman was not present to give his views in support of the Report. It must be a subject of congratulation and of great interest to the members of the Association to look back and see what had been done in regard to the matters dealt with in the Report. The Committee was appointed at the Dublin Meeting in 1867, and since that date very considerable and important results had followed from the Committee's labours. [*Hear, hear.*]

In the first place, after full consideration the Committee concluded that they could not deal with the questions involved as Associations, and that nothing less than the power of the State was requisite. [*Hear, hear.*] The Committee accordingly asked for a Royal Commission to investigate the subjects to be dealt with, and the Committee was successful, for the Royal Commission was issued. [*Cheers.*] It could not be too widely known that it was owing to the efforts of the Joint Committee of the two Associations that this Royal Commission was issued. That Commission had now reported; and he could say, though he did not agree with the Report, that the Commissioners had discharged their duty with zeal and intelligence; they had brought together a large amount of information which had never before been collected, and had laid the basis of legislation upon the subject. [*Hear, hear.*]

He had no doubt that within three years we should have upon the Statute Book an Act to consolidate the laws on this subject; and it was in a great measure to the number and the variety of the laws, and to the difference in their administration, that the evils existing were due, and much good would be done if the legislature could be induced to codify the sanitary laws. He did not agree with the proposed scope of the measure which purposed to deal with sanitary laws. He thought the measure would not work well if its area were to be limited to the hands of such small bodies as vestries and boards of guardians. The purposes of the measure were so diverse and inconsistent that they would require the most statesman-like and appreciative minds in a county to carry them out, and they should not be entrusted to any less body than that of a county representation. If the Associations pressed for this representation they would obtain it; and any educated man could see that it was impossible that these important duties could be entrusted to the representations of small areas. There was another point with regard to the appointment of health-officers which would have to be considered. The idea which had been broached as to the Poor-law medical officers being the health-officers was a grave mistake. No one had a higher opinion of the Poor-law medical officers than he had, but he held that they were not fitted to be the primary health-officers. They might be employed as the assistant health-officers, but the primary health-officers should be men

divorced from all State duties; they should be educated men, subject to no sinister influences from any quarter; and if men could be obtained of this character, improvement would soon be seen in the health of the people. [*Cheers.*] He could see why there was an endeavour to place the position of health-officers in the hands of underpaid and ill-educated men, and this was because the power of supervision should fall to some central authority. He hoped this would not be, for only those who knew a district could administer it. He did not wish to decry the usefulness of a central authority in some matters, but he did not think a central authority would be useful in this case. He trusted the Association would not relax its efforts in this direction, for the aim of the benevolent profession which this Association so ably represented was not only to cure disease but to prevent it; and if it brought its vast influence to this end it would continue the great work it had so well carried on.

Dr. LIDDLE (Whitechapel) seconded the motion, and said that when they saw the names of the gentlemen who had sat upon this Committee they were sure that the subjects dealt with in the Report would be pressed upon the Government. Nothing could be more absurd, he thought, than the making of a parochial or union area; but he was not quite sure that a county area was the right one. As an instance of the inconvenience of having a particular line of area, he referred to his experience of a nuisance arising on the borders of Essex, near where he lived on the borders of Middlesex, and the neighbours who experienced the effects of this nuisance could not interfere because they lived out of the county. He therefore thought that there should be some central authority to direct in such cases as this, for whatever area was fixed there would be people outside that area who would be affected by the nuisances within it, and they should have the power of dealing with it. [*Hear, hear.*] Respecting the Poor-law medical officers being health-officers, he agreed with the mover in thinking it would not be of advantage to have this combination. It was to be remembered that the Poor-law medical officers were under the local authorities, and most of the men composing the local boards were the owners of the property which was often needed to be reported on; and what, he would ask, would be the effect of the health-officer, who was also Poor-law medical officer, reporting upon a nuisance existing upon these properties? [*Hear, hear.*] This was a question he need not answer; and it must be apparent that a health-officer should be a gentleman having power over a large area, which was what a Poor-law medical officer could not have, for it was necessary that his attention should be confined to small localities. It was important for those whose care devolved upon Poor-law medical officers that these gentlemen should not have their attention diverted to the wants of a large district; and all officers of health should be gentlemen entirely independent of private practice. It was impossible to combine private practice with public duties, for the one was necessarily sacrificed to the other. He had been medical officer for the district of Whitechapel for many years, and had had experience of the working of the two positions, and he had been able to exercise power over matters with which he had to deal only because he was not dependent upon his position, but had private means.

Dr. STEWART said the question of area had purposely been dealt with in general terms. The Committee did not all go with the views of Mr. Hastings upon this point as to the area, and they went no further than to say that there should be full local inquiry made, so as to prevent any administration being settled upon defective data.

The report was then adopted; and, upon the motion of Mr. HASTINGS, it was agreed that the Committee should be reappointed.

Mr. ERNEST HART said some confusion was caused by the Committees appointed last year not being called together. He held that it was desirable a circular-letter should be sent by the Secretary informing gentlemen of the particulars of the Committees they were elected to, and of the time when they were to be called together.

It was agreed that the Secretary should issue such a circular-letter as was suggested.

Mr. T. WATKIN WILLIAMS, the Secretary, read the Parliamentary Bills Committees' Report (printed in the JOURNAL last week).

Mr. ERNEST HART moved that the Committee be thanked for their labours, the Report adopted, and the Committee reappointed. Dr. Stewart to be chairman and convenor. Facts, the mover said, came constantly within his knowledge to prove to him that no Committee of the Association rendered greater service to the profession and the public than this Committee. The Committee had had cognisance of every Bill affecting sanitary and social legislation, and members of the Committee were in constant attendance in the lobby of the House of Commons. He knew from personal experience that the Committee, as representing the Association, was much respected by the Committees of the House of Commons, the officers of the departments, and by the ministers themselves; and the Government now looked to the Com-

mittee for the Association's advice, action, and criticism, upon all subjects affecting the health of the people and the interests of the profession. [*Cheers.*]

The motion was seconded by Dr. LEWELLYN, and carried unanimously.

The Report of the Poor-law Committee (printed in last week's JOURNAL) was then brought up and read by Mr. E. Hart.

Mr. DYKE moved that the Committee be thanked for their labours, be reappointed, and that Mr. Ernest Hart be chairman and convener.

Mr. LITTLE took occasion to urge his objection to the system of gratuities, for paying per case gave rise, he said, to evils which were obvious. The vaccinator ought to be paid an adequate salary, and should not be placed in a position of competition with the other practitioners in his neighbourhood.

Mr. T. WATKIN WILLIAMS said he found his patients would not take their children to the public vaccinator, and that was the experience of others.

A MEMBER said that it would be an expensive process for the country if medical gentlemen were appointed to be vaccinators, and vaccinators only, for the districts throughout the country. He would support the views in the report, and he thought the Committee had done much for the Association; it had greatly increased the Association's influence, and it would do much more if individual members of the Association would bring their influence to bear upon members of Parliament. If members of the Association did this, the medical profession would exert its proper power in the State.

Mr. ERNEST HART stated that the Committee were very anxious to have the views of private members of the Association upon the several questions considered by the Committee.

Dr. HEAD added that he thought it was undesirable to have members of the medical profession vaccinators, and vaccinators only, for this would be a degradation to science, and would bring discredit upon a noble profession. [*Hear.*]

The motion was then carried *nem. con.*

Mr. E. HART drew attention to the fact that one other Committee had not brought its report up—a report bearing upon the collection of subscriptions by local secretaries. As this matter had not been submitted to the General Meeting, he thought the subject should be referred to the Committee of Council.

Mr. HUSBAND said he was glad, rather than sorry, that this report had not been brought before the meeting, for he thought such questions should be first dealt with on the Committee of Council.

Mr. T. WATKIN WILLIAMS said he had handed the report to a member of the Committee, and that this member had desired to make alterations.

Mr. E. HART said he should not accept the explanation; but he thought, with the Chairman of Committee of Council, that it was unnecessary to discuss the question then.

This subject then dropped.

Dr. FALCONER then moved votes of thanks to—The Mayors of Plymouth and Devonport; the Lords Commissioners of the Admiralty; Admiral Sir H. Codrington, K.C.B.; Vice-Admiral H. Stewart, C.B.; Inspector-General Davidson, C.B.; Captain the Honble. F. A. C. Foley; Major-General Sir W. Staveley; Colonel Westmacott, Royal Engineers; Colonel Clifford, Royal Artillery; Colonel Suther, Royal Marines; Dr. Gallwey, P.M.O. Citadel, Plymouth; Right Hon. the Earl of Mount Edgcumbe; Dowager Countess of Mount Edgcumbe; Right Hon. Earl of St. Germans; Earl Morley; Colonel Coryton of Pentillie; W. H. Pole Carew, Esq., of Antony; Admiral Tucker of Trematon Castle; W. Radcliffe, Esq., of Warleigh House; Sir Massey Lopes, Bart., M.P., Maristow; Chairmen of the Bristol and Exeter, South Devon, and Cornwall Railways; the Chairmen of South Devon and East Cornwall Hospital; of Plymouth Public Dispensary; of the Plymouth Institution; and of Plymouth Public and Cottonian Libraries; Dr. Barham and Members of the Royal Cornwall Institution.

Mr. SWAIN seconded the motion, and said that those members of the Association who had visited the neighbourhood for the first time, had found what the medical residents there had long experienced—that the officers of the army and navy and the gentry had the greatest respect for the profession, and, indeed, they had always treated its members with the greatest consideration. [*Cheers.*]

Mr. HUSBAND said he could not leave Plymouth without saying, on the part of the Committee of Council, that they fully appreciated the kindness which they had met with at the hands of the gentlemen in the locality. He suggested that the Secretary should be instructed to write to the gentlemen thanked, and convey to them these thanks in an official manner.

The vote was carried with acclamation.

Dr. HENRY proposed that the Association should give its warm thanks

to the Local Secretaries and the Treasurer for organising the successful arrangements which had been made for receiving the Association.

Dr. A. P. STEWART seconded the motion, and said what the gentlemen referred to had done had been carried out at great expense and anxiety. As this meeting was so large, the labour had been greater than in any other; and though the kindness of the Committee had been such as to diminish the value of the Association as a scientific meeting [*a laugh*], yet what had been done had been offered for the gratification of the Association.

The PRESIDENT bore testimony to the heavy work which Dr. Littleton had undertaken and carried out—work which entailed his continuing in harness from eight o'clock one morning until two the next; and said he well deserved the thanks of the meeting.

The vote was carried amid cheers.

Mr. HUSBAND then took the President's chair, vacated at this point, and he proceeded to propose a vote of thanks to Mr. Whipple, who, he said, during his long life and long professional career had gained the respect and esteem of all who knew him. [*Cheers.*] The President was an honour to the profession and the Association; and those members who had been present had much to thank him for in his personal kindness and for the manner in which he had presided over the meetings. [*Cheers.*]

Mr. HASTINGS seconded the motion, and said no one could take greater pleasure than himself in seeing the Association founded by Sir Charles Hastings under the presidency of a gentleman like Mr. Whipple. [*Cheers.*]

The motion was carried amid cheers, after a few words from Mr. SWAIN, who, as a young practitioner in the town, said he was happy to bear testimony to the upright and generous nature of the President.

The PRESIDENT briefly acknowledged the compliment paid to him by the Association, and the meeting then broke up.

#### THE DINNER.

The public dinner was held at St. George's Hall, Stonehouse, on Thursday evening. Upwards of two hundred gentlemen were present, and a repeat of the most *recherché* description was provided by Mrs. Budd, of the Duke of Cornwall Hotel. Mr. Whipple presided, and was supported by the Bishop of Exeter, the Mayor of Devonport, the Mayor of Plymouth, General Sir Charles Staveley, Professor Lister, Dr. Charlton, Mr. T. Woolcombe, Dr. Falconer, Dr. Sibson, Mr. Ernest Hart, Dr. Chadwick, and others. The band of the Royal Marines was specially engaged, and whilst justice was being done to the excellent things provided, the band performed a choice selection of music.

The CHAIRMAN, after the removal of the cloth, proposed the usual loyal toasts. He next gave "The Bishop and Clergy of the Diocese," and the toast was drunk with much enthusiasm.

The BISHOP responded, and met with a very hearty reception. After the applause had subsided, his lordship said he was very glad indeed to have the opportunity, not only of returning thanks to the President and members of the British Medical Association for the earnestness with which they had just drank the toast of the Bishop and Clergy, but also of expressing the warm feeling with which he was quite sure the whole of the profession he was connected with regarded the medical profession. [*Applause.*]

It might be that now and then there were differences of opinion between them. It might be that the clergy were looking to one thing when the medical profession were looking to another. It might be that the latter had to study the revelation that God had given in His works, and that the former had to study the revelation God had given in His word. It might seem to the clergy that those whom he was addressing did not lay stress enough upon the one, as no doubt it sometimes seemed to the medical profession that the clergy undervalued the other. Such differences there might always be; but he was sure they did did not mark the reality of conviction, and he thought and was sure they really would not keep them apart. He knew there were few who had better opportunities of recognising such a profession than the clergy. [*Cheers.*]

They all knew how much was owed to the medical profession. They all knew of the unwearied attention which constantly marked all that was done by the great body of the medical profession. The clergy knew better than many others how their hearts were in their work, and they knew how valuable that work was. They also knew what they had to do in this country in the great battle of sanitary reform which they had to fight. [*Cheers.*] They had to fight against the prejudices, ignorances, and vested interests of people who selfishly forgot that there were higher callings; but during that battle the medical profession would find that the clergy were heartily with them. The clergy desired their success, and they would do what they could to promote it, and as time went on, and the medical profession made further and further advances to do all it could to soothe human pain

there were none who would follow them with so warm an interest, who would watch them with so much admiration as that profession to which he belonged, whose duty was so kindred to their own—[*hear, hear*].—for they would never forget that when their Master came down, the way He took to prove that His mission was from Heaven was by going everywhere to heal the sick. [*Loud cheers.*]

The CHAIRMAN next proposed "The Army, Navy, and Volunteers," coupling with the toast the name of Sir Charles Staveley.

Sir CHARLES STAVELEY, in responding, wished to be permitted to say that the British army was at present in the hands of the doctors. The patients complained of the want of proper circulation. There had been no end of prescriptions, but the doctors were at variance, and they were to have a surgical operation on the 1st November next. [*Laughter.*] Some thought that would be a complete cure, but some considered the after treatment would be homœopathic. Be that as it may, he was sure the British nation would not spend £16,000,000 without looking to an effective army one day or another. [*Hear, hear.*] It was a most satisfactory thing to find the interest the nation had taken in the Berkshire campaign. With regard to the navy, he would say that accidents would happen in the "best regulated families." Ships would get ashore now and then, but he thought they would agree that the navy was never in a better condition than it was at the present time—as good as any two navies in the world. [*Loud applause.*] In the campaigns with which he had been connected he had learnt that the army owed much to the medical profession. [*Applause.*]

The CHAIRMAN proposed "Prosperity to the British Medical Association."

Dr. HUSBAND was called upon to acknowledge the toast. He spoke of the society as the most influential and the greatest medical association that ever existed. It was a society which had held its own against the most powerful Government. [*Hear, hear.*] The British Medical Association went on year by year increasing, until it had attained in point of numbers the position to which it was entitled. Last year they were in the north, and this year they had been invited to the splendid locality of Plymouth, where he was afraid there had been a strong rivalry between the charms of scenery and science. The sections, perhaps, had not been so largely attended as they might have been, but the community would have a great advantage, for many would go from Plymouth refreshed by the splendid scenery, and with health and vigour to carry on their labours, labours which were for the lessening of pain and sorrow. [*Cheers.*] They had to thank the Chairman, and those amongst whom they had come, for their splendid hospitality, and for the sympathy and kindness which they had everywhere met. But whether they came from the north, or whether they were residents in the south, they were each determined to do the best they could for the community to which they belonged. [*Applause.*] He referred to his connection with the Association, which had extended over thirty years, and concluded by proposing the health of Mr. Whipple, speaking of him as an excellent example of the good old English gentleman, and one who had done so much to promote the good of the meeting. [*Cheers.*]

Dr. WHIPPLE, in responding, said he felt a little nervous after the high and what he could not but deem lavishing compliment paid him by his respected friend who had just sat down. When the requisition was presented to him asking him to accept the recommendation of the Medical Society of the North of England he was astonished beyond measure, indeed he was flattered to the utmost possible degree; and, although he differed with the medical men who signed that requisition, he felt, however unequal he might be to perform the task, it was his duty to comply. He had done so, and he could assure them that he had not had any occasion to regret it, except it was a feeling that they might have chosen a far better man. [*Cries of "No, no."*] He did not, notwithstanding, disguise himself of the fact that for the past forty years he had worked hard and industriously in raising himself to the elevated position he then occupied. [*Hear, hear, and cheers.*] When he came to Plymouth he knew only one individual, and he need hardly add he felt in no small degree flattered now to possess the acquaintance of so many friends as he did, and especially to be paid so great a compliment as he enjoyed by the visit of so great an Association to the south of England. [*Hear, hear, and cheers.*] It was true he lived a long way off in the far west, and for men whose time was fully occupied, and whose brains were at work day and night to promote medical science, to visit this neighbourhood he could not but regard as the highest compliment that could be paid to him and others. They had been very fortunate, for while the members had been enabled to attend here in the path of duty, they had, at the same time, had an opportunity of devoting a portion of their time to pleasure. [*A laugh.*] He hoped on another occasion to join them again, if not at Plymouth, elsewhere, and with results as satisfactory as they had been at Plymouth. [*Cheers.*]

Dr. SIMON proposed "The health of the President-elect, Mr.

Baker," and, in so doing, observed that no doubt it was very difficult for the members, amid so many beauties and interests which Plymouth could pride itself upon to keep within the strict objects of the Association. They were, however, about to transfer their next meeting to the very centre of the land, to a town the type of England, a place full of work, pervaded with smoke, and where everything spoke of labour. They would find there a number of gentlemen who were zealously devoted in the development of true medical science. The change would be from the exquisite country which gave birth to Sir Walter Raleigh, to the land which prided itself on the true English characters of Watt and Bolton. It was true he laboured under somewhat a difficulty, because he only had three days' acquaintance with Mr. Baker. It would be vain, therefore, on his part, to speak of the President-elect's merits. This, however, he was sure, judging from what he had heard, Mr. Alfred Baker was the right man in the right place. They would find around him a band of hard working medical men, true and hospitable in trying to do their work well. [*Cheers.*] In conclusion, he coupled the name of Mr. Baker with the toast.

In the absence of Mr. Baker, Mr. WADE replied, and expressed a hope that they would be satisfied with the reception they would meet with when they visited Birmingham.

Dr. CHADWICK gave the health of the Treasurer, Dr. FALCONER, who responded, and concluded by proposing the healths of their Irish and Scotch members.

Mr. LEICESTER responded in an appropriate speech.

Dr. RADCLIFFE HALL proposed, in a very able and eloquent speech, the healths of the Mayors of Plymouth and Devonport, and said that people often heard of *esprit de corps*, but here the Association had seen *esprit de corporation*.

These gentlemen responded, and acknowledged in very grateful terms the flattering way the members of the Association had thought fit to speak of the entertainment afforded them.

The healths of the readers of addresses in medicine and surgery, readers of papers, the general secretary, the local secretary and his co-secretaries, and "Our Next Merry Meeting," brought the proceedings to a successful close, the concluding speakers being Dr. Charlton, Dr. Johnson, and Professor Lister.

## MEETING OF COMMITTEE OF COUNCIL,

*Held at Plymouth, August 8th, 1871.*

PRESENT: W. D. Husband, Esq., F.R.C.S. (in the Chair), Dr. Falconer, Mr. Baker, Mr. Clayton, Dr. Littleton, Mr. Heckstall Smith, Dr. Chadwick, Mr. Whipple, Dr. Sibson, Dr. Charlton, Mr. Harrison, Dr. Wilkinson, Mr. Nicholson, Dr. Bryan, Mr. Southam, Dr. Philipson, Dr. Edward Waters, and Mr. Williams, General Secretary.

The following resolutions were agreed to.

"That the army and navy medical and surgical staff be invited to attend the meetings of the British Medical Association; and that they consider themselves as members of the Association during the meeting in Plymouth."

The Report, as prepared by the President of Council, the Treasurer, and the Secretary, was considered, and, after some few alterations, was approved.

*Meeting of Committee of Council, held at Devonport, August 9th, 1871.*

Present: W. D. Husband, Esq., F.R.C.S. (in the Chair), Dr. Falconer, Mr. Baker, Mr. Sibson, Dr. Stewart, Mr. Clayton, Mr. Andrew Davies, Dr. Fothergill, Dr. Wilkinson, Mr. Southam, Dr. Underhill, Mr. R. Harrison, Mr. Heckstall Smith, Dr. Chadwick, Dr. Steele, Mr. Nicholson, and Mr. Williams, General Secretary.

The following resolutions were adopted unanimously.

1. "That Mr. Watkin Williams be requested to continue his services as Secretary up to the 31st of December next; and that he be presented with the sum of two hundred pounds, instead of the usual salary; and that the thanks of the Association be given to him for his zealous services during the eight years he has held the office of Secretary.

2. "That a Subcommittee be appointed to define the duties of the 'Secretary and Manager of the Journal Office', and to issue the necessary advertisements."

T. WATKIN WILLIAMS, *General Secretary pro tem.*  
13, Newhall Street, Birmingham, August 16th, 1871.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, AUGUST 19TH, 1871.

### THE ANNUAL MEETING.

THE annual meeting has closed, leaving all those who have visited Plymouth deeply and pleasurably impressed with its agreeable incidents. They were favoured by unclouded skies, and welcomed in a locality which combines the charms of exquisite land- and sea-scape with the varied animation and striking spectacles of a great port and arsenal, spreading contiguous moors, ancient keeps, and modern grounds, of singular beauty; and those who were most bent on holiday making were puzzled to know whether they should devote themselves to the inspection of the breakwater, the Eddystone Lighthouse, Brunel's masterpiece (the Albert Bridge), the iron-clad forts, the turret-ships, the gunnery and torpedo experiments, the review, the ships and victualling yards; or to the beauties of the Dart, the Tamar, and the Yealm; the ancient memories of Cothele; the more modern beauties of St. Germain's and Mount Edgecumbe; the bay and caves of Torquay, or the wilds of Dartmoor. Some conscientious lovers of laborious relaxation found opportunities, we verily believe, to explore all these sources of gratification without failing to do justice to public and private entertainments in the spare hours. So large a contingent of the Association have penetrated into the fastnesses of Cornwall, and are occupied with inspecting dolmens, menhirs, and cromlechs, that at this moment the inhabitants of that province are probably in better plight for medical aid of any kind than any other in the kingdom. The sudden taste for archæological research developed by so large a number of our associates is a surprising proof of their skilful versatility. It will be seen that the exertions of the local Committee and its officers, and the great courtesy of the resident gentry and local authorities, as well of the Three Towns as the two services, placed before the members so full a programme of interesting occupations and of healthful and delightful relaxation, that it is hardly surprising that the scientific ardour and the weight of sacrificial business duties were largely outmatched by the counter-attractions under their eyes. On the first night the general meeting was well attended; the second and third day the attendances faded away; until at last only such admirable utterances as those of Dr. George Johnson and Professor Lister could hold an audience together; and even for papers so widely interesting as those of the Public Health Section, the audience in the sections barely exceeded a score. On the last day of the meeting it became almost impossible to hold more than a faithful few to their work. The papers read were, however, in many cases, of high value, and had audiences "fit though few". Many of them will amply repay publication *in extenso*, and of these we shall present the full text, while all will appear in abstract, with reports of the discussions which occurred. It was the standing consolation of an eminent magistrate to those about him who complained of the narrow limits of the court, that "We sit in the newspapers". This will also be the

satisfaction to those authors of papers whose auditors were more select than numerous. Every annual meeting has its own characteristic features by which it is afterwards specially remembered. The annual meeting at the Three Towns will, we think, long live in the memory of those who constituted it as one of the most enjoyable ever held.

It will be a matter for serious consideration at the next and subsequent annual meetings whether it will not be desirable to subdue the otherwise naturally growing tendency to allow the holiday making to override the scientific and working objects of these annual meetings. The annual meetings of the Association offer the finest professional platform which exists for the propagation of opinions in the profession, the publication of researches, and the enunciation of facts. In no other way and at no other time can they be placed before so large a critical audience, receive so universal a journalistic circulation, or attract so much attention here and abroad. The natural course of events would be, therefore, that these meetings should continue to attract papers of more and more value; and it was the operation of this cause, and the great increase in the scientific *prestige* of the Association, which necessitated recently the formation of a multiplicity of sections. The reaction from the years of sectional activity to those of continuous pleasure-making requires to be checked. Next year will afford a favourable opportunity for steering a course which will consist with the happy medium. The immediate natural attractions of Birmingham are not so overpowering as those of the Three Towns. And although the well known hospitality and public spirit of the profession in Birmingham, their numbers, social position, and earnestness of purpose, will most certainly succeed in giving features of great attraction to the renewed visit of the Association to the town which claims to be considered as its cradle, the managers of the meeting will succeed without difficulty in so moderating the extraneous attractions as to keep members free from irresistible temptations to desert the sectional and general meetings. For this purpose it may be desirable to give up the public breakfasts and to commence sectional business at nine o'clock each morning. If each section had the opportunity of sitting for nine hours—three each day—that might suffice for a great deal of work; the general meetings might be held from twelve to two each day, and the afternoons left free for those outings and healthful amusements of which medical men in August know well the value, feel the necessity, and appreciate the pleasure. Some such scheme, or a variation from it, keeping the same-ends in view, would meet, what we gather from numerous sources to be, a general desire.

The meeting now concluded has, however, been remarkable for important business changes, of which we relegate the discussion to another place. It has been distinguished for the excellence of its annual addresses, for the great importance of the reports of committees presented, for the unmistakable evidences of the constantly growing power, the political and social usefulness of the Society, and the earnestness and devotion which its most active members bring to its important work. The reports of the Committees tell their own tale.

Never before has the Association covered so large a ground of public usefulness, or influenced so strongly public opinion. It does so by virtue of its great and growing numbers, of its educated intelligence, of its high aims, and of the singleness of

purpose with which those aims are supported. In proportion as these qualifications are strengthened will it flourish and continue to extend benefits to the profession and the public. To insure success in that high endeavour, we need only adopt the motto of the Three Towns which have just earned our gratitude for a memorable reception—ONE AND ALL.

#### MEDICAL REFORM.

THE subject of medical reform has again been brought before a general meeting of the Association. Dr. Charlton, the retiring President, in his valedictory remarks, while expressing regret that the last year had not been marked by progress in medical legislation, stated that all that had occurred tended more and more to confirm the oft repeated declaration of the Association that no measure of medical reform will be acceptable to the profession which does not embrace the two propositions—viz., the one single portal by which all shall enter the medical profession, and the full and adequate representation of the whole body of the profession on the General Medical Council. The Report of Council declared that the Reform Committee had strictly adhered to the principles enunciated and repeatedly endorsed at the general meetings of the Association.

On Thursday, August 10th, the day appointed for receiving the Reports of Committees, precedence was given to the Report of the Reform Committee of the Association nominated at Newcastle. Dr. E. Waters, the Chairman of the Committee, read the Report, which specified in detail the labours of the Committee in settling the clauses of the Bill of the Association; the arrangement with the Right Hon. Mr. Headlam, M.P., and Mr. Dalrymple, M.P., to introduce the Bill into the House of Commons; and the notice given by Mr. Headlam of his intention to bring it in. The Bill of the Association was based on that of the Government of last year, but modifying the powers to be granted by it to the Privy Council, and appointing direct representatives of the profession on the General Medical Council to the extent of one-fourth of its numbers. This Bill embodied the demands of the Association; but two other Bills, widely differing from each other, were also subsequently given notice of by members acting in the interests of the *Lancet* and the Irish College of Surgeons. Mr. Headlam thereupon urged the Committee not to press their Bill, as by so doing the profession would present a divided appearance before the House, and damage the cause of medical reform. The Committee felt bound to adopt Mr. Headlam's advice, on account of his weight and long and extensive experience. They refrained from pressing the Bill of the Association. The other Bills, though unopposed by the Association or its Committee, no sooner reached the stage of the second reading than they were withdrawn; and the session was thus lost to medical reform. The principles contended for by the Association have, however, acquired increased force. For the fifth time they have again been placed before a general meeting of the Association, and have been unanimously approved. The Reform Committee has been reappointed; and it may with reason be fairly hoped that success will yet crown the efforts of the Association.

#### OUR SISTER SOCIETY.

THE members of the British Association have held a special meeting, of which a brief note will be interesting and suggestive to our members. The Association is weak, notwithstanding its great popularity, the two or three thousand pounds collected as "gate-money" at its annual meetings, the numerous local subscriptions by which its expenses are annually defrayed, and the liberal grants of Government and the generous donations of individuals. The "want of union" is felt, and a very general craving for that support which a powerful organisation lends to the efforts of individuals. The Association, it was pointed out, takes one huge meal a year, and lies in a semi-dormant state during the rest of the period; and the question before the meeting was,

whether its habits could not be altered for the better. Its energy is magnificent, but at the same time discontinuous and spasmodic; and, though the inhabitants of cities such as Dundee or Bradford may for once in a generation receive a visit from the Association, for twenty or twenty-five years they are left to grow up—and they do grow up—in ignorance of the very existence of this great peripatetic body. Could the Association retain a more permanent hold upon these large towns, it would surely be of advantage to both parties. The town, on the one hand, would greatly benefit by being kept in connexion with the central body; whilst the Association, on the other, would gain in influence, not to mention meaner considerations of a metallic nature. Existing local scientific societies might be organised as autonomous with associated branches, their proceedings published throughout the year, and political influence would be acquired. In other words, the leading spirits of the British Association are proposing to assimilate its constitution to that of the British Medical Association—no small compliment to the wisdom of the founders of this Society, who placed early in the hands of the medical profession the means of becoming, unaided by subsidies, and by small annual subscriptions, possessed of a powerful social and political organisation, a continuous record of their scientific proceedings, a complete local system of connected societies communicating by a weekly sheet, and operating through a common centre. This organisation the great sister Association, rich in all that constitutes material and intellectual wealth and prosperity, is now endeavouring to emulate.

#### THE UTILISATION OF SEWAGE.

MR. HOPE's paper on this subject, at the Public Health Section of our annual meeting, excited considerable interest, and we shall take an early opportunity of presenting it either in summary or at length to our members. The members of our profession are largely consulted on this subject by public authorities, and are deeply interested in obtaining accurate information on this vital subject of modern economics—how best to live on the earth in masses without defiling or impoverishing the soil and water. At the meeting of the British Association at Edinburgh which has just closed, this subject was much debated, and a valuable preliminary report was brought up from the Committee on the Utilisation of Sewage, to whose proceedings we have already referred, and towards whose expenses of investigation various corporations have subscribed £1600. The experiments are still in progress. Mr. Hope gave in a detailed report on the experiments made at Breton's farm. He stated that in the three hundred and seventy-three days, from June 12th, 1870, to July 15th, 1871, the amount of town-sewage received was 85,999,445 gallons, giving a daily average of 230,562 gallons. The effluent water discharged on to the farm in the same period amounted to 39,449,178 gallons, giving a daily average of 115,012 gallons. The diluted sewage pumped on to the farm was 96,944,653 gallons, giving a daily average of 264,876. The temperature of the sewage and effluent water was found to be very uniform as compared with that of the air, being lower during extreme heat and higher during extreme cold. This was very noticeable during the severe frost of last winter.

Reports were read of the Earlswood sewage farm, and the irrigated lands of Tunbridge Wells, both of which seem to be conducted on defective principles and to yield results satisfactory, but less so than might be attained by providing for a more efficient sort of filtration. An interesting report furnishes us with information as to Forbes and Price's process, which it may be well to note. This process, it was stated, was in operation at Tottenham. The sewage, after passing through some depositing tanks which had been constructed for the lime process, was pumped up at the rate of 800 or 1000 gallons per minute along a carrier into a tank a hundred yards long, and of gradually increasing breadth. This tank took three hours to fill. As the sewage passed along the carrier the chemicals were mixed with it thus: Two boxes were placed over the carrier—one a few yards further along it than the other; the first contained the phosphate mixture, and the second milk of lime;

men were continually stirring the contents of each box, which were allowed to run continuously into the sewage as it passed beneath the boxes. The amount of the preparation added was not ascertained, but it was stated to be certainly much less than the proportion indicated by previous experiments (one ton to 500,000 gallons of sewage). The result of this preparation was to deodorise the sewage to a very considerable extent indeed; and when some of it was placed in a precipitating glass and allowed to stand, a speedy separation of the suspended matters took place. The milk of lime was added to precipitate the excess of phosphate added, and just sufficient milk of lime was allowed to flow in to neutralise the sewage—the reaction of which to test paper was obtained from time to time after the addition of the milk of lime. During the passage of the sewage thus treated through the large tank, the suspended matters were very completely deposited, and the supernatant body ran over the sloping edge of the tank at its extreme end, bright and clear, and almost odourless. Some of this water was collected, and was kept sealed up in a stone-jar until July 24th, when it was analysed by Dr. Russell. It was found after the interval of four months quite sweet, and without smell. The suspended matter was in very small quantity, and consisted merely of a little whitish flocculent matter—doubtless lime, due to the slight excess used on the day when the sample was collected. The water was quite clear, and only on looking through a considerable depth could a brownish tint be detected. The analysis of it showed that it contained as much actual ammonia as ordinary dilute London sewage, and also a certain amount of albumenoid ammonia. It contained the merest trace of phosphoric acid, as indicated by the molybdate of ammonia test, and no sulphuretted hydrogen, nor any nitrates or nitrites. Some of the deposit had been taken out of the tank, and was drying in a shed, the water which separated from it forming little pools on the surface of the moss. Both this water and the precipitate itself were free from all offensive smell. It appeared, then, that the suspended matters were entirely removed by this process, but the actual ammonia, and, to a certain extent, the soluble organic matters, were entirely removed from the sewage when oxidised; but an odourless precipitate was produced which contained all the phosphate added, and contained it, doubtless, in the form of flocculent phosphate of alumina, the value of which as a manure was somewhat doubtful, being certainly not as great as the value of corresponding quantities of flocculent phosphate of lime. The valuable constituents of sewage, with the exception of the suspended matter and the phosphate acid, were not precipitated by this process, and could not be utilised unless the effluent were afterwards used for irrigation, in which case the milk of lime would not be added, and the clarified sewage would still contain a quantity of phosphoric acid. The advantages of its use, if it were found to answer, from an economical point of view, would be the deodorisation of the deposit in the tank and of the sewage itself, which was certainly at present a great desideratum, especially as regarded the tank.

A very strong opinion was expressed that more ought to be heard about Leighton's process, and that the Association ought to report upon it. This is a very interesting process, which is in use at Newcastle-under-Lyne, and may be distinguished from the plans of irrigation and precipitation as that of filtration. The principal article there used as a filtering medium is charcoal, which every chemist knows to be the best deodoriser which can be applied. Mr. Leighton pointed out that the question of the treatment of sewage requires, for its satisfactory solution, two results—first, that the effluent water shall be pure; and second, that this shall be done economically. Now, as to the first point, the effluent water, according to Weare's process, is far purer than that of the best that has been named as resulting from irrigation; and as regards the second, the process can be carried out at a large profit. It is obvious that irrigation, in its most perfect form, can be applied only where the neighbouring land is exceptionally suitable. For general application, it is entirely unsuitable. Even under the best circumstances, it gives a surplus of manure to a small area of land, and leaves the rest of the country starved of necessary fructifying elements. By Weare's process, on the contrary, the whole of the valuable properties of the

sewage is arrested and manufactured into a form capable of distribution over the whole country in a perfectly innocuous form. By it, in fact, the circle is completed; the elements withdrawn from the country in the form of food are again returned to it in the form of manure—and the value of the manure has been determined by practical experience. The farmers who used it the previous year were so satisfied with its results that the applications for it were this year far greater than could be met. The company could have sold six times the quantity their works were able to produce. And when it is mentioned that the cost of the materials used, and of their manipulation, does not exceed £2 per ton, while the manure sells readily for £4 per ton, the economy of the process becomes manifest. Moreover, it is capable of universal application. It is a mere question of the multiplication of works. The results are in all respects superior to any which have been exhibited in the reports we have just heard; and as the object of the appointment of a Committee of the British Association was to obtain information on the best methods of the utilisation of sewage, he hoped that next year the omission he had now pointed out would be supplied.

It is satisfactory to know that Dr. Cobbold has microscopically scrutinised an ox fed from the sewage-grown plants of Buta's farm, and found the beast free from parasites of every kind,

---

THE Cape mail, which arrived this week, brings news that the Assembly there have repealed the Contagious Diseases Acts.

---

THE Westminster Hospital received on Thursday last a second donation of £1000 from a kind and unknown benefactor, under the initials Z. D. W.

---

THE *Times* Constantinople correspondent telegraphs that cholera and fever are reported to continue raging in Persia; but the Persian authorities unfortunately take no precautions, and are said to be astonished that Turkey is adopting preventive measures.

---

THE *Times* of India says that cholera has broken out at Lingah, in the Persian Gulf; and the mail steamers have not been calling there of late in consequence. Cholera also exists at Bahrein, on the Arab littoral, and in the Turkish camp at Khatif. Dr. Hart, of H.M.S. *Euphrates*, serving in H.M.S. *Magpie*, in the Persian Gulf, has died of cholera at Bahrein.

---

THE COLLEGE OF PHYSICIANS' LECTURES.  
THE next Harveian oration will be delivered by Dr. Arthur Farre, the Lumleian Lectures by Dr. Quain, the Croonian by Dr. Wilks, and the Gulstonian by Dr. Hensley.

---

MEDICAL QUALIFICATIONS.  
THE following analysis of the medical licences possessed by the 133 candidates examined at the last meeting of the Court of Examiners of the Royal College of Surgeons of England may be interesting to our readers. M.D. Edinb., 1; M.D. Toronto and Queen's University, Canada, 3; M.B. Edinb., 3; M.B. Aberd., 2; M.B. Dub., 2; M.B. Toronto, 2; L.R.C.P. Lond., 2; L.R.C.P. Edinb., 6; L.R.C.P. Edinb. and L.S.A. Lond., 3; L.S.A. Lond., 27; L.F.P. & S. Glasg. and L.S.A. Lond., 1; and L.K. & Q. C.P. Ireland, 1.

---

SMALL-POX IN BRECON.  
WE learn from the *Brecon County Times* that there has been an epidemic of small-pox in that place. It appears, according to the statement of the physician to the Brecknock Infirmary, that there have been forty-two cases, five of which were fatal, giving a death-rate, he says, of nearly 12 per cent. Thirty-nine out of the total number of cases were in one parish—St. John—and nine of this number of cases had never been vaccinated. The writer in question adds: "It is indeed sad to think that as many as 23 per cent. of these cases were totally unprotected by vaccination." This is a case, surely, in which a little official stirring up might be beneficial.

## REPORTED ASIATIC CHOLERA AT WEST HARTLEPOOL.

ON Tuesday morning, an alarming, but happily to some extent unfounded rumour, gained publicity in West Hartlepool. On the previous morning, an ironworker in that town was seized with alarming symptoms of illness. Dr. Sutherland, who saw the case, at once pronounced it to be a case of aggravated choleraic diarrhoea. The case proved fatal.

## MEMORIAL OF THE LATE DR. TANNER.

A MOVEMENT is on foot to perpetuate the memory of the late Dr. Tanner. It is proposed, if a sufficient amount be raised, to devote the interest of the principal to establish an annual "Tanner Scholarship", to be competed for by students, and awarded for proficiency in diseases of women. Some particulars are given in the circular which has been issued, and which is published elsewhere.

## SEABOARD PREPARATIONS FOR CHOLERA.

THROUGH the early and energetic steps taken by the Privy Council, and the tour of Mr. J. Netten Radcliffe, the north-eastern ports and towns of England are more or less prepared to meet cholera should it appear, and now Mr. Radcliffe is about to proceed to the south-eastern ports on a similar mission. The port of London and the mouth of the Thames have been committed to the especial charge of Dr. Buchanan.

## HEALTH OF THE CAMP AT SHOEBOURNNESS.

THE health of the camp, notwithstanding the great heat, has been throughout good. Mr. J. Wickham Barnes, the Senior Surgeon in charge of the medical arrangements, informs us that one hundred and twenty persons received medical relief, the majority of cases being consequent on exposure to the sun, ophthalmia, diarrhoea, and colic, more especially at the commencement of the meeting, and one case of small-pox, which was immediately removed to an isolated ward in the Royal Artillery Hospital. To obviate as much as possible illness from exposure to the sun at future meetings of the Association, the medical staff were unanimous in recommending that all volunteers attending the camp should be provided with proper head-gear and loose holland blouses. The medical officers appear to have received much courtesy and kindness from Colonel Chermiside, the Camp Commandant, and from Dr. Harrison, R.A.

## THE INTRODUCTORY ADDRESSES AT THE LONDON SCHOOLS OF MEDICINE.

THE Winter Session at the metropolitan medical schools will be opened on October 2nd, when the introductory addresses will be delivered by the following gentlemen. At Charing Cross Hospital, by Dr. T. H. Green; Guy's Hospital, by Dr. Oldham; King's College, by Dr. Rutherford; London Hospital, by Dr. W. J. Little; the Middlesex Hospital, by Dr. John Murray; St. George's Hospital, by Dr. John Clarke; St. Mary's Hospital, by Dr. Alfred Meadows; St. Thomas's Hospital, by Mr. Le Gros Clark; Westminster Hospital, by Dr. Basham. No introductory address will be given at St. Bartholomew's Hospital. The Lecturer at University College has not yet been appointed.

## DIARRHOEA IN LONDON.

THE fatal cases of diarrhoea, which in the three previous weeks had been 110, 201, and 224, further rose last week to 299, exceeding by 50 the average number of fatal cases returned in the corresponding week of the ten years 1861-70, after correction for increase of population; this increase, however, was scarcely so large as might have been expected from the excessive temperature which prevailed. These 299 deaths from diarrhoea last week included 234 of infants under one year of age, 34 aged one year, and but 31 of children and adults aged above one year. To cholera and choleraic diarrhoea 15 deaths were referred last week, against 17 and 18 in the two preceding weeks; 13 were of infants not exceeding one year, and two were adult females, both certified as "choleraic diarrhoea."

## GUY'S HOSPITAL.

IN consequence of the closing of St. Thomas's Hospital at the Surrey Gardens, and the delay in the opening of the new hospital at Stangate, nearly all the accident cases occurring on the south side of the river have been brought here during the last month, as well as the more urgent medical cases.

## SMALL-POX IN THE METROPOLIS.

THE deaths from small-pox in London, which in the six previous weeks had declined from 235 to 87, slightly increased again last week to 96; of these, 41 occurred in five temporary hospitals for this disease, including 16, 13, and 10 respectively in the institutions at Hampstead, Homerton, and Stockwell.

## FEMALE STUDENTS IN PRUSSIA.

THE Königsberg academical authorities, having addressed a question to the Minister of Public Education (Herr von Mühler) concerning this matter, have received a reply from this dignitary which frustrates the hopes of the fair aspirants. The statutes of the University, he says, contain no provision for the case of a female student. Indeed, a like thing had not been thought of at the time of their being framed. It would therefore be necessary, he further argues, to alter the statutes, for which His Excellency, as at present advised, cannot see any cause. Then follows a categorical interdict against the admission of female persons to University lectures.

## AUSTRALIAN MEAT.

THE *Food Journal*, in commenting on Australian meats, says that the great mistake which is liable to be committed is this, to expect that preserved meat, even when presented with the appearance of freshness, can ever compete with the fresh meat of this country; but, in truth, there is no necessity that it should. The working classes of this country do not live wholly on fresh meat. They freely consume salt beef and pork, bacon, ham, dried and salt fish; and there is an opening for preserved meat at a moderate price, as an addition to the food-supplies of the country. If the quantity of bacon imported could be doubled, it would be a great boon; but it will be a still greater boon to obtain increased supplies of colonial meat, which may approach more nearly in character to fresh meat.

## THE LADIES AND THE UNIVERSITIES.

PROFESSOR MACDONALD, M.D., St. Andrew's, writes as follows on this subject.

"The shabby manner, to use no harsher term, in which the Senatus of the Edinburgh University has treated the ladies who were induced to matriculate as medical students two years ago, with the purpose of obtaining the degree in medicine to enable them to enter the practice of the medical profession, will be generally disapproved of, preceded as it was by the hasty, vindictive action of damages against Miss Jex Blake. Though a change of opinion may have induced a majority in the Senatus to alter the regulation regarding matriculated lady medical students, yet in common fairness to those ladies who had for two years practically engaged in the less attractive department of practical anatomy, should have been allowed to complete their curriculum of study. The threat to deprive those qualified medical lecturers of the Royal Colleges who were willing to lecture to the ladies is another instance of unfairness to all parties—at the same time it is not so harsh as it appears to be, as it only debars their lecturing to matriculated ladies. They may still instruct those who desire to receive a medical education beyond the walls of the Edinburgh University. All I have argued for is, that ladies should have the benefit of the very varied, extensive, and practically useful medical education. It is by no means necessary that all who are so educated should enter the practice of the profession—as is frequently the case with gentlemen. At the same time, some few may possess sufficient firmness of character and strength of matured constitution to fit them to endure the constant fatigue of practice, especially in the obstetric department and the treatment of the diseases of women and children. If we refer to the conditions of the curriculum of medical study, it is expressly stated to be completed in four years, and that a medical annus consists in attending either two six months' courses of lectures, or one of six months and two of three months during

the same year. It further provides that at least two of the four medical years shall be at a University embracing four six months' courses of lectures, and that all the other lectures may be attended beyond the precincts of the University. Therefore, if Miss Jex Blake or her fellow medical students have completed one or two medical years at the Edinburgh University, they may complete their whole medical curriculum where they choose, without further let or hindrance. As the medical faculty of the St. Andrew's University are favourable to the medical education of ladies, the second University medical year could be passed there, after completing the other subjects with the Royal College lecturers. Although there is not at present any general hospital, as it has been proposed to get a Ladies' Medical Hospital, I think it not unlikely that such an institution might be favourably supported in St. Andrew's. This would at once be followed by some additional medical lecturers, so that a more extended course of instruction, both in medical and general knowledge, might easily be secured in a nice healthy locality with good society. Referring to the vindictive persecution of Miss Jex Blake, I think for her clever and spirited conduct at the Infirmary meeting, and the active zeal with which she has carried on the whole movement, I think she is well entitled to have a public testimonial presented to her, for which I have subscribed five pounds, in hopes that a large number may be led to subscribe."

#### THE USE OF SECONDARY LYMPH.

OUR Manchester correspondent writes that the extent to which revaccination has been practised in Manchester during the last few months, has afforded rare opportunities for deciding some questions which were before held by some to be still *sub judice*: for example, the custom which has prevailed among the millowners of having all their work-people vaccinated, has settled the question of the value of secondary lymph, as compared with virgin lymph. Out of many similar experiences, the following may be quoted by way of illustration. A fortnight ago, a surgeon vaccinated 300 operatives; in 150 of these cases he employed virgin lymph; in the remaining 150, secondary lymph was used. The first series gave the following results: 19 cases were unsuccessful; in 16 cases, small papules and spurious vesicles resulted, while the remaining 115 all showed well marked primary vesicles. The second series gave very different results; for out of them, 50 were entirely unsuccessful, 86 terminated in papules and small spurious vesicles, only 14 yielding true primary vesicles.

#### THE RED CROSS AND FOREIGN DECORATIONS.

A MOTION asking permission for British subjects to wear foreign decorations offered for services rendered with Her Majesty's permission to the sick and wounded in the late war was negatived in the House of Commons on Friday of last week. It was pointed out that their acceptance could be restricted only to services performed in presence of the enemy, or while serving in a foreign country with the permission of the Crown. The object of the regulations of the Foreign Office was stated by Lord Enfield to be to prevent political intrigue, and to disturb them would lead to an immense amount of influence being brought to bear on the Foreign Secretary. On a later evening, however, Mr. Gladstone expressed a desire to relax the rules now in force, if the Secretary of State for Foreign Affairs, after inquiry into the matter, considered that they could be modified for the public advantage.

#### MEDICAL EXPERTS IN COURTS OF LAW.

MR. LAWSON TAIT sends the following reply to the letter of Mr. Lane and Mr. Norton, which appeared in last week's JOURNAL.

"Messrs. Lane and Norton go into the merits of the legal bearings of the case of malpraxis to an extent that I do not care to imitate. I care as little for their opinions as they seem to do for mine, and have no wish to prolong the discussion further than to say that the statement italicised in their letter, and on which their case would depend, were it true, is not correct. In the case they speak of, *the nasal septum has not fallen in, neither is the nose completely flattened*. The lower third of the nose is drawn backwards and the nostrils widened by the absence or altered position of the nasal spines of the superior maxille, but the bridge of the nose is quite entire, the case thus differing most materially from one of syphilitic destruction of the septum, and where the bridge falls in and the lower third becomes prominent by contrast. I never by any word or words ever hinted that the evi-

dence of the two 'London hospital surgeons,' Messrs. Lane and Norton, was less honest and conscientious than my own. My evidence was simply a narration of the facts of the case. I resolutely declined to give any opinion of the matter. Messrs. Lane and Norton, on the other hand, dealt with opinions founded on no facts whatever. And here I may say, that I had no knowledge, until I read their letter, that it was intended that I should meet Messrs. Lane and Norton, or that they were engaged on the case; otherwise I might have saved them the trouble of giving evidence. With the legal bearings of the case I have, as I said before, nothing to do; but I insist that the opinions given that the plaintiff's condition was to be explained by syphilis were rash and not in the least degree supported by the facts of the case."

#### MR. RICHARD WALLACE OF PARIS.

It is stated by one of our daily contemporaries that a baronetcy is to be conferred on Mr. Richard Wallace, in recognition of his noble services during the siege of Paris.

#### THE CHOLERA ALARM IN LONDON.

CONSIDERABLE and uncalled for alarm was created in London on Tuesday by the prominent appearance of a letter in the *Times*, signed "James Edmunds, M.D.," in which the writer authoritatively stated that he had been called to a typical case of Asiatic cholera in Charlotte Street, Portland Place, at a very early hour that morning. On investigation, however, by one of the medical officers of the Privy Council, it was found that there was no reason to believe the case to be one of Asiatic cholera. The patient had been taken ill while returning from a school-treat. If Dr. Edmunds, instead of posting down to the *Times* office at three o'clock in the morning, and rushing precipitately into print to the unnecessary alarm of the metropolis, had communicated his story to the proper sanitary authorities, he would have been directing his energies in a better way. Dr. Edmunds has forwarded to us for publication a full account of the history and symptoms of this now notorious case, which no doubt in many respects resembled Asiatic cholera; but this is not the point at issue. Cases of choleraic diarrhoea are seen every autumn by practitioners, which, during an epidemic of Asiatic cholera, would very probably be classed as cases of that disease; but there was no reason to believe that, in the present instance, the case was anything more than one of this character assuming a severe type. Therefore, Dr. Edmunds was, we think, not at all justified in alarming the public mind as he has done. Mr. Forster's suggestion in the House of Commons on Tuesday evening should be borne in mind, that medical men, if they entertain suspicions regarding cases of diarrhoea, should communicate with the sanitary authorities, whose duty it is to carry out disinfection.

#### CHARGES AGAINST THE MANAGEMENT OF THE ROYAL ORTHOPÆDIC HOSPITAL.

CHARGES of a very serious character were brought by several members of the medical staff against the Committee of Management of this Hospital at a coroner's inquest recently held, which were fully published in the daily papers, and have caused considerable public attention. It appears that a child, five years of age, had been admitted for operation, and had died in the hospital a short time ago from diphtheria, and that since the month of April twelve others, including one of the nurses, had contracted the same disease, which proved fatal in the case of the nurse and five of the children. In addition to these cases of diphtheria, several of the patients had previously to this outbreak died of scarlatina. It was now alleged that all these deaths had been accelerated by the sanitary condition of the hospital. Dr. Matthew Wilks Bourne, the house-surgeon to the hospital, said that upon entering on his duties four weeks ago he found the general and sanitary arrangements of the hospital as bad as they could possibly be, both in regard to the diet, the cooking, the cleanliness, and the knowledge and attention of the matron and nurses. There was no order or regularity. The patients were left unwashed for days together, and the atmosphere of the wards was damp and moist, owing to the washing and scrubbing taking place at all hours of the day, instead of early

in the morning; that the walls of the wards were always wet with moisture, owing to this cause, and that all sorts of slops were thrown down the baths in the wards by the nurses. He believed all these deaths to have arisen entirely from the wretched sanitary condition of the hospital and the defective and neglectful system of nursing. He had frequently got up in the night to attend to the children while crying, the nurses not paying any attention to them. On the 3rd of August, before the death of the deceased, he had sent in a written report to the Committee, describing the condition of the hospital. He attended before the Committee, and read that report himself. While before the Committee he also made a verbal communication as to the gross mismanagement he had witnessed in the wards. He then left the Committee-room, and in five minutes afterwards he received a written note from the Committee requesting him to send in his resignation, on the alleged ground that he could not agree with other officers of the hospital. He admitted that several sanitary improvements had been carried out in the institution, but that the state of the hospital was still very defective. Mr. Tamplin and Mr. William Adams corroborated in many points the evidence of Dr. Bourne, both of whom stated that they had made complaints to the Committee, which had not received the attention which they deserved. The jury, after some deliberation, returned the following verdict: "That the deceased died from diphtheria; but we recommend the Committee to adopt and act upon the suggestions of their medical officers, especially with respect to the appointment of a regularly trained nurse." The publication of so many alleged acts of mismanagement will form abundant material for discussion by the general body of governors, which meets shortly. We have personally inquired into a number of the statements made, and visited the hospital; and, although we do not at present feel justified in giving a decided opinion on the results of our inquiry, we are confident that, in many points at least, the allegations of the medical staff are correct. The hospital, as regards cleanliness, is amply capable of improvement. Its arrangements are bad in many ways, and the nursing department especially requires reform. At the same time, we could not fail to observe, and it is only fair to say so, that the Committee have endeavoured in many ways to remove objectionable hygienic arrangements. At a meeting of the Committee held on Thursday evening, it was decided to postpone the consideration of the house-surgeon's conduct and the charges against the Committee and hospital authorities. The house-surgeon's resignation was accordingly not pressed.

## SCOTLAND.

### CHOLERA ON BOARD A DUNDEE BOUND SHIP.

Information from Dantzic, dated August 7th, says: "The *Progress*, Innos, from Königsberg, for Dundee, has put into the bay, with one seaman dead and another sick with cholera."

### INFIRMARY AND DISPENSARY FOR STIRLING.

It has been decided to erect an Infirmary and Dispensary at Stirling to supply a want much felt in the town and neighbourhood and the western district of Perthshire. The sum already subscribed for the erection of the hospital amounts to £2350, and for the annual maintenance £150.

### THE ABERDEEN ROYAL LUNATIC ASYLUM.

The medical report of this old asylum, drawn up by Dr. Jamieson, the medical superintendent, has reached our hands. Medically speaking, the report gives ample evidence of the continued success of the institution. Physically, the matter contained in the report does not recommend itself to us. Dr. Jamieson finds it necessary, and we think with justice, to protest against the low rate charged for the treatment of pauper lunatics, which, if it covered expenses before, is now stated to be quite inadequate, since so many of the lunatics who require little attention and entail little expense on the institution are now removed to the fattens' wards of the poorhouse. If this be really the

case—if it be true that an institution in which the charitable element largely predominates is allowed to suffer in order that the rates may be kept down—the public should certainly know it. Dr. Jamieson says that "unless its annual income for some years to come exceeds its expenditure by a sum not less than £2000, it must be considered to be in a bad financial position." This we regret to hear, but unless the managers afford the charitable public ample evidence that Dr. Jamieson is mistaken, and that pauper lunatics cease to be treated to the detriment of the institution, we presume there is little chance of so large a sum finding its way annually into the hands of the Treasurer.

### THE GLASGOW WESTERN INFIRMARY.

THE foundation-stone of this institution was laid with masonic honours on the 10th instant, that date having been probably fixed in order to take advantage of the presence of many who had been celebrating the centenary of Scott the evening before. The procession was a somewhat imposing one, including the Provost and magistrates, the Professors of the University, the Fellows of the Faculty of Physicians and Surgeons, as well as the usual masonic array. The hospital is in process of erection on a slight elevation just behind the University buildings, and a portion of it has already reached the basement storey. It is proposed, when the hospital is complete, that it shall contain about three hundred and sixty beds, but in the meantime only a portion of it is being proceeded with, the requisite funds for the whole undertaking being still wanting. It is proposed to erect in the first place, then, a portion capable of accommodating about 150 beds, and as funds are obtained the rest will be proceeded with. It is a pity that both the University and this hospital should remain in an unfinished state, but, considering the large amount which has been already subscribed, it can cause no wonder if a few years should elapse before a great effort can be made to raise the requisite funds.

### LEITH: PRECAUTIONS AGAINST CHOLERA.

PRECAUTIONS are being actively taken to prevent the spread of cholera should it appear in Leith. The Old Charity School, King Street, has been acquired, and will be fitted up as a hospital for patients suffering from any epidemic that may visit the town. The building at the end of the West Pier has likewise been obtained, where cholera patients who may arrive in ships from foreign ports will be attended to. Notice has been given, by order of Her Majesty's Privy Council, to all ship-owners, shipmasters, and pilots, that any ship arriving in the roadstead from any infected port, must be inspected by the medical officer before it enters the harbour, and before landing any person or thing therefrom.

## IRELAND.

### BEQUESTS TO HOSPITALS IN DUBLIN.

MR. MULLINS, of Fitzwilliam Square, has left the following handsome bequests to Dublin hospitals: £1,000 to the Hospital for Incurables, £500 each to St. Vincent's, Jervis Street, and the Mater Misericordiae hospitals, and the residue of his fortune, amounting to over £10,000, to trustees, for the purpose of building a convalescent home.

### THE IRISH AMBULANCE.

M. THIERS has appointed Mr. O'Scanlan, the Director of the Irish Ambulance during the war, to be a Chevalier of the Legion of Honour. The principal persons connected with that ambulance will also receive decorations.

### PRECAUTION AGAINST CHOLERA IN IRELAND.

THE supplement to the *Dublin Gazette* contains two orders in council respecting sanitary precautions against cholera, specially referring to steam ships.

# THE CHOLERA.

## PRECAUTIONS AGAINST CHOLERA.

THE following memorandum on precautions against the infection of cholera has just been issued by the Medical Department of the Privy Council, and we earnestly impress upon all local authorities, medical officers of health, medical practitioners, and the public generally, the necessity for their becoming acquainted with this very salutary memorandum of advice.

1. As Asiatic Cholera is now prevailing in foreign ports within a week's voyage of this country, and may probably extend to others which have still quicker communication with England, it is not unlikely that, within the next month or two, occasional cases of the disease may be brought into the ports of this country.

2. A recent Order of Council, dated July 29th, has given power to the respective local authorities to deal with any such cases, if they arrive, in a way to protect the population, as far as practicable, against surprise. But as cases of choleraic infection have innumerable degrees of severity, it is possible that some such cases, slightly affected, will, notwithstanding the vigilance of local authorities, be landed without particular notice in English sea-board towns, whence then they may advance to other, and perhaps inland, places.

3. Former experience of cholera in England justifies a belief that the presence of imported cases of the disease at various spots in the country will not be capable of causing much injury to the population, if the places receiving the infection have had the advantage of proper sanitary administration; and, in order that all local populations may make their self-defence as effective as they can, it will be well for them to have regard to the present state of knowledge concerning the mode in which epidemics of cholera (at least in this country) are produced.

4. Happily for mankind, cholera is so little contagious, in the sense in which small pox and scarlatina are commonly called contagious, that, if reasonable care be taken where it is present, there is scarcely any risk that the disease will spread to persons who nurse and otherwise closely attend upon the sick. But cholera has a certain peculiar infectiveness of its own, which, *where local conditions assist*, can operate with terrible force, and at considerable distances from the sick. It is characteristic of cholera, not only of the disease in its developed and alarming form, but equally of the slightest diarrhoea which the epidemic influence can cause, that all matters which the patient discharges from his stomach and bowels are infective, and that, if they be left without disinfection after they are discharged, their infectiveness during some days gradually grows stronger and stronger. Probably, under ordinary circumstances, the patient has no power of infecting other persons except by means of these discharges; nor any power of infecting even by them, except in so far as particles of them are enabled to taint the food, water, or air, which people consume. Thus, when a case of cholera is imported into any place, the disease is not likely to spread, unless in proportion as it finds, locally open to it, certain facilities for spreading by *indirect infection*. In order rightly to appreciate what these facilities must be, the following considerations have to be borne in mind:—*first*, that any choleraic discharge cast without previous thorough disinfection into any cesspool or drain, or other depository or conduit of filth, infects the excremental matters with which it there mingles, and probably to some extent the effluvia which those matters evolve; *secondly*, that the infective power of choleraic discharges attaches to whatever bedding, clothing, towels, and like things, have been imbued with them, and renders these things, if not thoroughly disinfected, as capable of spreading the disease in places to which they are sent (for washing or other purposes), as, in like circumstances, the cholera patient himself would be; *thirdly*, that if, by leakage or soakage from cesspools or drains, or through reckless casting out of slops and wash-water, any taint (however small) of the infective material gets access to wells or other sources of drinking-water, it imparts to enormous volumes of water the power of propagating the disease. When due regard is had to these possibilities of indirect infection, there will be no difficulty in understanding that even a single case of cholera, perhaps of the slightest degree, and perhaps quite unsuspected in its neighbourhood, may, *if local circumstances co-operate*, exert a terribly infective power on considerable masses of population.

5. It might be supposed that under those provisions of the Sanitary Act, 1866, which relate to precautions against dangerous infections of disease, security could be taken, as regards the infective discharges of cholera, against various kinds of personal conduct which would be dangerous to the public health; above all, that, under those provisions or otherwise, the universal disinfection of such discharges could be enforced. Undoubtedly everything possible in this direction ought to be done, wherever a case of cholera is known to exist; too much importance cannot be attached to the precaution of thoroughly disinfecting, without delay, all discharges from the stomach and bowels of persons suffering under the disease, as well as all bedding, clothing, towels and the like, which such discharges may have imbued; and of course neither choleraic discharges, nor any slops which may contain traces of them, should ever (even when supposed to be disinfected) be cast into any position from which they may get access into drinking-water. The duty of observing those precautions is one which ought never to be neglected; but populations cannot prudently stake their lives on the chance that it will be completely fulfilled for them. Apart from all questions of negligence, the degrees of cholera are too many, and the slight and incept cases far too apt to escape observation, for any such defence against its infection to be more than partial. And the main object for endeavour must be to secure such local circumstances that cholera-contagium, though not disinfected, shall be unable to act extensively on the population.

6. The dangers which have to be guarded against as favouring the spread of cholera-contagium are particularly two. First, and above all, there is the danger of water-supplies which are in any (even the slightest) degree tainted by house-refuse or other like kinds of filth; as where there is outflow, leakage, or filtration, from sewers, house-drains, privies, cesspools, foul ditches or the like, into streams, springs, wells or reservoirs, from which the supply of water is drawn, or into the soil in which the wells are situate: a danger which may exist on a small scale (but, perhaps, often repeated in the same district) at the pump or dip-well of a private house; or on a large and even vast scale, in the source of supply of public water-works. And, secondly, there is the danger of breathing air which is foul with effluvia from the same sorts of impurity. Information as to the high degree in which these two dangers affect the public health in ordinary times, and as to the special importance which attaches to them at times when any diarrhoeal infection is likely to be introduced, has now for so many years been before the public, that the improved systems of refuse-removal and water-supply by which the dangers are permanently obviated

for large populations, and also the minor structural improvements by which separate households are secured against the dangers, ought long ago to have come into universal use. So far, however, as this wiser course has not been adopted, temporary security must, as far as practicable, be sought in measures of a palliative kind. (a.) Immediate and searching examination of sources of water-supply should be made in all cases where the source is in any degree open to the suspicion of impurity; and the water both from private and public sources should be examined. Where pollution is discovered, everything practicable should be done to prevent the pollution from continuing, or, if this object cannot be attained, to prevent the water from being drunk. (b.) Simultaneously, there should be immediate thorough removal of every sort of house-refuse and other filth which has accumulated in neglected places; future accumulations of the same sort should be prevented; attention should be given to all defects of house-drains and sinks through which offensive smells are let into houses; thorough washing and lime-washing of uncleanly premises, especially of such as are densely occupied, should be practised again and again. (c.) Disinfection should be very freely and very frequently employed in and round about houses, wherever there are receptacles or conduits of filth, wherever there is filthy-sodden porous earth, wherever anything else, in or under or about the house, tends to make the atmosphere foul. In the absence of permanent safeguards, no approach to security can be got without incessant cleansings and disinfections, or without extreme and constant vigilance against every possible contamination of drinking-water. [For detailed advice on disinfection, see the office Memorandum on that subject.]

7. In view of any possibility that the infection of cholera may again be present in this country, it is desirable that in each locality the public should ascertain to whom it practically has to look, in case of need, for its collective safety against such dangers as the above. The responsibility is, in a large proportion of cases, mixed. The most critical of all its branches, the responsibility of providing for the unpollutedness of water-supplies, is, in many very important places, in the hands of commercial companies; and it is to be hoped that these companies, informed as they must be of the calamitous influence which some of their number have exerted in previous epidemics of cholera, will remember, if the disease should again be present here, that each of them, in its daily distribution of water, has hundreds, or even thousands, of human lives in its hands. But, except to that extent, the responsibility for local defences against cholera, both as regards water-supply and as regards local cleanliness and refuse-removal, is vested in the Local Authorities—the "Sewer-Authorities" and "Nuisance-Authorities" of recent statutes. These Authorities—the Town Councils, Improvement Commissioners, Local District Boards, Boards of Guardians, and select and common Vestries, of their respective areas of jurisdiction—are all, either electively or directly, so constituted as to represent the will of the local rate-paying population; and each such population has had almost absolute means of deciding for itself whether the district which it inhabits shall be wholesomely or unwholesomely kept. It is greatly to be wished that the former of these alternatives had, from long ago, been the desire of every local constituency in the country. It may fairly be believed that, in considerable parts of the country, conditions favourable to the spread of cholera are far less abundant than at former times of visitation; but it is certain that in very many places the conditions of security are wholly or almost wholly absent; and it is to be hoped that, in all this large class of cases, the authorities, under present circumstances, will do everything which, in the remaining time, can be done to justify the trust reposed in them by the Legislation for the protection of the public health.

8. It is important for the public very distinctly to remember that pains taken and costs incurred for the purposes to which this Memorandum refers, cannot in any event be regarded as wasted trouble and expense. The local conditions which would enable cholera, if imported, to spread its infection in this country, are conditions which day by day, in the absence of cholera, create and spread other diseases—diseases which, as being never absent from the country, are, in the long run, far more destructive than cholera; and the sanitary improvements which would justify a sense of security against any apprehended importation of cholera would, to their extent, though cholera should never reappear in England, give amply remunerative results in the prevention of those other diseases.

By direction of the Lords of the Council, (Signed) JOHN SIMON.  
Medical Department of the Privy Council Office, April 10th, 1871.

## THE CHOLERA IN GERMANY.

REPORTS from Königsberg dated August 15th, state that on Saturday last 40 persons were attacked by cholera, 19 deaths occurring from the epidemic on the same day. On Sunday, 38 were seized, and 16 died. The police authorities have ordered that no vessel shall be allowed to leave the port of Königsberg without having its crew medically examined. At Neufahrwasser, some cases of cholera had occurred on board ship. Dantzic is still untouched. The authorities have taken the most stringent measures to prevent its being imported. The news that cholera had broken out at Elbing is unfounded.

Later reports from Königsberg (August 16th) state that the number of persons attacked with cholera the day before yesterday was 62, and the deaths from that disease 22.

THE CHOLERA.—The Corporation of Rochester have made the necessary arrangements for a supervision over ships arriving in the port in case any persons suffering from cholera should be brought in them. They have also prepared for a strict sanitary supervision of the city. The Chatham Board of Health have done the same for the town of Chatham.

BREACH OF QUARANTINE.—At Hull, on Wednesday, the master of a vessel trading to Cronstadt was summoned for a breach of the Privy Council quarantine orders. The defendant had taken his ship into dock, in the midst of the town, before the crew had been medically examined, although he had been warned. His excuse was that he could not afford to lose a tide. Mr. Travis imposed the maximum penalty, £20, and expressed the opinion that it was not sufficient to meet the case.

## THE BRITISH ASSOCIATION.

## SECTION D—BIOLOGY. DEPARTMENT OF ANATOMY AND PHYSIOLOGY.

*Monday, August 7th.*

This section met in the Anatomy Class Room, Dr. Allen Thomson presiding.

*Report on the Heat of the Blood during Arterialisation.*—Dr. ARTHUR GAMGEE, F.R.S.E., read a report on this subject, in which he drew attention to the researches of previous observers, stating that these had been carried on with imperfect methods. He first quoted the results of his experiments on the specific heat of blood, which showed that this was almost exactly the same as that of water—experiments which were necessary in order to proceed to a determination of the heat of arterialisation. He then described the elaborate apparatus which he had devised, and proceeded to state the results at which he had arrived. From his experiments on the heat of arterialisation of perfectly reduced blood, he has arrived at the conclusion that the mean rise in temperature during the absorption and combination of oxygen with the blood-colouring matter of perfectly reduced blood, amount to 0.097 of a degree centigrade. The maximum heating found was 0°.111 c., and the minimum, 0°.083 c. The author then made observations on the total amount of heat units representing approximately the heat due to the arterialisation of the whole blood passing through the lungs in a day. The amount of blood passing through the lungs in one day amounts to more than ten tons, and it was estimated that the heat resulting from the arterialisation of the whole blood amounted to 527 heat units (the heat unit taken being the kilogramme of water heated 1° c), an amount more than sufficient to heat the whole quantity of air inspired, and to saturate it with moisture at the temperature of the body.

Dr. RUTHERFORD said that the subject had puzzled many investigators, but the report Dr. Gamgee had given of the heat of the blood was highly satisfactory. He hoped Dr. Gamgee would continue to work at the subject, in order to obtain the heat of the venous blood which went to the lungs, and had no doubt that his results in regard to that would also be satisfactory.

Some remarks were afterwards made by Dr. Ray Lankester, Professors Rutherford and Williams, and the President.

*Experiments on Inoculation in the Lower Animals.*—Dr. JOHN CHIRINEZ then read a paper on "An Experimental Inquiry into some of the Results of Inoculation in the Lower Animals." The paper described a series of experiments, in which rabbits were inoculated with cancerous matter obtained from the human subject. The result may be shortly stated in the following words:—(1) That cancer cannot be produced in rabbits; (2) that cysts, containing cheesy matter, arise at the points of inoculation; (3) that these cysts do not differ from the local appearances which arise after the application of any irritant to the subcutaneous tissue of the rabbit.

Professor WILLIAMS said he had had some experience in inoculation both with rabbits and birds. The birds he had experimented upon numbered fifty or sixty, but they all died, the cause of their deaths being the inoculation; but he did not find it so with rabbits. He thought that in birds inoculation produced infection.

Several other members took part in a discussion which followed.

*Diets in the Workhouses of England and Wales.*—Dr. EDWARD SMITH, F.R.S., Medical Officer of the Poor-law Board, read a paper on "The Dietary in the English and Welsh Workhouses." He referred to the fact that schemes of dietary are agreed upon by the combined action of the local authorities, the guardians of the poor, and the central authority; and showed that, as the dietary should correspond with that of the labouring classes, it must vary in different localities, and be based upon knowledge. The dietary is thus prepared by the guardians, and examined and sanctioned by the Poor-law Board. He explained the steps which have recently been taken by the latter to give advice to the boards and to establish greatly improved dietaries. This was initiated by the Hon. C. F. Villiers, who first made the appointment of medical officers to the Board, and carried into effect by the Earl of Devon and his successors as Presidents of the Poor-law Board. It is now laid down by that authority that the foods to be selected shall be those in ordinary use in the several localities, and that the kind and quality of food shall be adapted to the wants of the several classes of inmates. The chief differences of food are found in the quantity of meat supplied and the mode in which it is served, and the use of oatmeal, cheese, milk, and puddings. In many of these points the dietaries in Dorset and Westmorland were contrasted. Then he showed, from inquiries made by

him for the Government some years ago, that the quantities of food obtained by the working classes per adult weekly were, in Dorset—bread-stuffs, 13 lb.; sugar, 3½ oz.; fats, 4½ oz.; meat, 7½ oz.; milk, 12 oz.; and cheese, 12½ oz.; while in Westmorland the quantities were—bread-stuffs, 12½ lb.; sugar, 10½ oz.; fats, 6½ oz.; meat, 21½ oz.; milk, 120 oz.; and cheese, 2 oz. He then showed what is the typical diet of children at various ages, and to able-bodied and aged adults, and the quantity of the several foods in workhouses. Children under two years of age get milk, bread, and rice pudding; from two to five years, pudding on three days, meat and potatoes on three days, and soup or other food on one day. From five to nine years there is one other day of meat and potatoes, and commonly one of soup. From nine to sixteen that of adults. For able-bodied, bread and gruel at breakfast and supper, varied by broth or cheese in the several localities; at dinner, meat in some form on four days, and pudding or cheese on three days. For aged, tea and bread and butter at breakfast and supper; at dinner, meat in some form five days, with pudding or cheese or other food on two days. The standard of measurement of the sufficiency of this food is that which he gave to the Government when advising on the Lancashire cotton famine—viz., 4,300 grains of carbon and 200 grains of nitrogen daily; and the model dietary which he had framed for the Midland Counties supplied more than this to the adults. He then pointed out, whilst the above-mentioned quantity of food supported the health and strength of the inmates, except perhaps as regarded children, there are still many workhouses where the dietary is very unsatisfactory. In some, gruel and bread are given at breakfast and supper to nearly all the inmates, or where meat in a separate form is not given, or where a very small quantity, as two ounces or three ounces of raw meat two or three times a week, or where bread and cheese alone are given to some classes in eighteen out of twenty-one meals weekly, or where soup containing no meat is given thrice a week, or where meat when given is given only when cold; whilst, on the other hand, there are workhouses in the manufacturing districts where meat and bread are given in great excess. He was of opinion that the time may arrive when the Government will prepare several schemes of dietary for different parts of the country; but in the meantime, improvements are now in rapid progress. He exhibited tables showing the quantities of food taken by the working classes, and the dietary which he had recommended for use in workhouses in the Midland Counties; and he also read the details of the dietary which Professor Christison had desired for the Edinburgh charity workhouse in 1854, supplying oatmeal and butter milk at breakfast and supper, and meat soup with bread at dinner.

*Tuesday, August 8th.*

Professor FLOWER, F.R.S., read a paper on "The Composition of the Carpus in the Dog." Professors TURNER and STRUTHERS on "The Anatomy of Certain Whales." The Professor, in concluding, alluded to the great difficulties, and even risk to health, attending the dissection of these enormous animals. It was difficult to say whether it was worse on the sea-shore in a wet day, or in the confined and putrid atmosphere of the College-room. No one who had not tried it could realise the difficulties.

*Muscular Anomalies on the Darwinian Theory of the Origin of Man.*—Professor MACALISTER communicated a paper on this subject. He set out by stating that three arguments from anatomy are usually brought forward in support of the evolution theory of the origin of man. The first of these is derived from embryology, the second from rudimentary structures, and the third from anomalies. The object of this paper is to endeavour to determine the precise value of the last of these arguments. This may be stated thus:—It is the experience of anatomists that structures are variable, and that in scarcely two subjects are the parts similar to each other, and often very great varieties are noticed. As these varieties simulate the normal arrangements in lower animals, it is inferred by some that they are evidences of a genetic affinity. The first point to determine is—Do the anomalies of parts in man resemble the normal structures of lower animals? The evidences in determination of this point were drawn by the author from the muscular system, and he classified muscular anomalies according to their relation to lower animals. The first class consists of those separate muscles which are normal in lower animals, and only rarely present in man—such are the muscles known as occipito-scapular, peroneus quinti, levator, clavicle, etc. The second class consists of those separate muscles which exist as anomalies in man, but do not exist as normal in lower animals, such as the cystic abnormal laryngeal muscles described by different authors. The third class consists of such muscles as are distinctive of man, and which are sometimes anomalously absent in him, and, still more rarely, some of the peculiarly human muscles are rarely present as anomalies in lower animals. The fourth class consists of muscles common to man and other animals, but which normally are differently arranged in both.

In man such muscles are often found arranged according to lower animal types, and this class contains by far the largest number of anomalies. How to account for these anomalies has long been a point of dispute. There are two hypotheses which seem competent to account for them. One large series like the second class is accounted for on functional grounds; but this hypothesis is incompetent to explain the occurrence of all, as some anomalies are sources of weakness, and absolutely destroy function. That function is a factor, however, seems plain from three considerations:—1, muscles which have a great variety of function have a wide range of variation; 2, muscles which have no function, like those of the whale's paddle, are very variable; 3, those muscles which have single definite functions vary very little. The second hypothesis is that of reversion, that such anomalies are produced by the tendency to revert to some earlier structural condition of some former stage of parental condition.

In the course of a discussion which followed, Professor MACALISTER thought we were shut up at present to the evolution hypothesis, and the proper way to pursue this investigation further would be to tabulate all the muscular anomalies in man, and do the same in regard to the lower animals, and compare the two so as to see whether the grouping of anomalies in man was the same as in the lower animals. He had drawn out such a table regarding man, and would leave it to some one better qualified than he was to make out a similar table regarding the lower animals.

Subsequently Professor RUTHERFORD, F.R.S.E., London, exhibited a model of the circulation constructed by him with a view to elucidate the phenomena of the pulse and the blood pressure. With the aid of the apparatus, he showed how the pulse is produced, why it is that with dilated capillaries there is a pulse in the veins, and why there is no pulse in the veins when the capillaries are contracted. He further showed why it is that the arterial is higher than the venous pressure, and the causes of variation in the amount of the arterial pressure.

Dr. E. RAY LANKESTER read a paper "On the Existence of Hæmoglobin in the Muscular Tissue, and its relation to Muscular Activity."

Dr. ARTHUR GAMGEE read a paper "On the Magnetic and Diamagnetic Properties of the Blood."

The Section then rose.

*Spontaneous Generation.*—Dr. FERRIER gave an account of certain experiments made by him in conjunction with Dr. Burdon Sanderson, with a view to discover the circumstances which determine the existence of bacteria in the liquids and tissues of the body. The paper had reference to certain results obtained in the course of an investigation into the ultimate nature of contagion. It was shown that in the test liquids which they used for the detection of organisms in contagious fluids, no spontaneous evolution of organisms takes place. The occurrence of organisms in these liquids was in proportion to the degree of external contamination. Fungi (*penicillium*) is the chief form which is derived from the air. The occurrence of bacteria is, however, due to water. It was shown that every kind of water, with the exception of freshly distilled water, teems with invisible germs of bacteria. These cannot be detected by the microscope, or by the electric beam in the manner adopted by Professor Tyndall. The purest-looking ice-water was found to contain as many germs as others which had not the same apparent purity. Different varieties of water possess the zymotic power, as they term it, in different degrees. The water supplied by the London water-companies was examined, and different degrees of bacteria impurity were found to exist. They further showed that the animal liquids and tissues do not in the normal state contain the germs of bacteria, and that the occurrence of these, and consequent putrefaction, was due to contact with surfaces or ordinary water. Bacteria seemed to be the pioneers, if not the producers, of putrefaction. It was found that meat, milk, wine, etc., do not putrefy if they are kept from contamination with water, or any surface which has not been superheated, or rendered innocuous by some anti-zymotic which is fatal to the life of bacteria. The experiments further showed that there is no developmental connection between bacteria and torula—consequently Hallier's theories fall to the ground.

Dr. JOHN DOUGAL read a paper "On the Relative Powers of various Substances in Preventing the Generation of Animalcules, or the Development of their Germs, with special reference to the Germ Theory of Putrefaction."

Dr. CHARLTON BASTIAN described some new experiments he had made in relation to the origin of life, and said that the result of these led him to the conclusion that living matter might arise *de novo*, and that this living matter might go on to the development of certain common organic forms, just as surely as any speck of crystalline matter in a fluid might take on and assume certain definite characters which belonged to that saline substance in its crystalline condition. His experiments

showed that living organisms had been found in fluids exposed to a temperature higher than was sufficient to destroy germs.

In the course of some discussion,

Dr. M'KENDRICK said that the experiments he had made did not warrant him in adopting the conclusions on either side of the question. With regard to Dr. Bastian's experiments, he observed that the germs or ova of living creatures must always be more delicate and likely to be destroyed than the creatures themselves.

Dr. LANKESTER considered the question to be still open. He did not see why theologians should denounce the supporters of spontaneous generation, because the Church in former ages had believed that organic beings might arise from inorganic substances. Dr. Bastian wished them to believe that his experiments had proved spontaneous generation; but there were other and more interesting spheres of observation, and he (Dr. Lankester) thought that it was in the slimy deposits in the depths of the sea that they must look for the solution of the difficulty. The question should not be regarded as irreligious. Philosophers were quite justified in looking for the truth, and no theory or view should be suppressed that might at last turn out to be true.

Professor ALLEN THOMPSON, in closing the Section, thought he should not be acting unfairly in saying that the question was still undecided. [*Hear, hear.*]

A paper was given in but not read, on account of the want of time—"On the Origin and Sources of Fibrin in the Animal Economy", by Dr. John Goodman.

## MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Monday, August 14th.

THE CONTAGIOUS DISEASES ACT.—On vote 9 of the Army Estimates, a long discussion on the working of the Contagious Diseases Acts was raised by Mr. W. Fowler, who moved to omit the pay of the police employed under the Acts. He took the opportunity of discussing the recent report of the Commissioners, and drew from it materials for impugning the principle of the Acts.—Mr. Henley also spoke earnestly against this legislation, and warned the House against departing in these matters from moral principles founded on Christianity.—Mr. Bruce, on behalf of the Government, urged that it was impossible for them to sweep away those Acts at once in the face of the evidence as to the diminution of vice and disease which they had brought about, and of the admitted necessity to replace them by legislation of a wider character, as to which the Government had not had the opportunity yet to make up its mind.—Mr. Tipping approved the general working of the Acts, and with much antiquarian learning—going back as far as forty centuries—argued that repressive measures had always failed.—Mr. Mundella, on the other hand, opposed the Acts, and quoted some of the most unsavoury details of the evidence against them.—Mr. G. Gregory complained of the unfairness of calling on the House to decide in the absence of the evidence; and Mr. Percy Wyndham condemned the not always unintentional misrepresentations of the opponents of the Acts; while Mr. R. Gurney supported the reduction of the vote with a view of stopping compulsory examination; and, after some observations from Mr. Cardwell, deprecating precipitate judgment, Mr. Fowler's amendment was negatived by 56 to 44.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.

THE following is an abstract of some of the unconfirmed minutes of the meeting of the Council on the 10th instant.

Messrs. John Taylor Porter, L.S.A., and James Gleadall, L.S.A., both of Sheffield, elected Fellows of the College on the 13th ult., were admitted as such, their diplomas of membership bearing date respectively April 22nd and August 21st, 1840; and Mr. John Buck Stedman, L.S.A., of Godalming, Surrey, was elected a Fellow, his diploma of membership bearing date March 5th, 1841.

The Council having confirmed their resolution of the 13th ult., removing Mr. Frederick Henry Morris from being a Member of the College, it was resolved that the Secretary do inform him of such removal, and do call upon him to return his diploma, as required by Clause 5, Section XVII, of the Bye-laws; and that Dr. Hawkins, the Registrar to the General Council of Medical Education and Registra-

tion, be informed that his removal was in consequence of his conviction for a criminal offence.

The following donations were accepted, and thanks of the Council voted:—From Sir William Fergusson, Bart., a copy of the engraving of Henry VIII presenting the Charter to the Barbers and Surgeons, and a copy of the same in oil; from Mr. Edward Cock, three copies, in different stages, of the engraving of Sir Joshua Reynolds's picture of John Hunter, together with an engraving of the picture of Sir Astley Cooper.

Letters were read from Drs. Hawkins, Carpenter, and Pitman, representing respectively the General Medical Council, the University of London, and the Royal College of Physicians, in reference to the formation of a Joint Examining Board for each division of the United Kingdom. The scheme was approved by the University of London, subject to a slight alteration in Resolution X thereof; and also by the Royal College of Physicians.

Mr. Birkett, in the absence of Mr. Quain, and in pursuance of the notice given by the latter at the last meeting of the Council, moved that a Committee be appointed to investigate the expenses of the College in all its departments, and to report thereon, with a view to the diminution of expenses where practicable; and, the motion having been seconded by Mr. Hancock, and the votes of the Council taken thereon, a majority was in favour thereof; whereupon Messrs. Hilton, Quain, Hawkins, and Birkett, were elected members of such Committee.

Mr. Hawkins gave notice of the following motion for the next meeting of the Council after the quarterly meeting in October; viz., to take into consideration the question of placing those who pass the examinations for the fellowship in classes according to merit.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, August 10th, 1871.

Garton, William, St. Helen's, Lancashire  
Pearce, Joseph Channing, The Manor House, Brixton  
Wheeler, Daniel Martin Brumwell, Chelmsford, Essex

The following gentlemen also on the same day passed their first professional examination.

Hansell, William Charles, Guy's Hospital  
Kewson, Andrew Emerson, Guy's Hospital  
Le Mottée, George Herbert, King's College  
Paul, Frank Thomas, Guy's Hospital  
Spark, Sidney Walter, Guy's Hospital  
Whitmore, William Tickle, St. Bartholomew's Hospital

**ARMY MEDICAL SERVICE.**—List of the candidates of Her Majesty's British Medical Service who were successful at the competitive examinations held at London in February, and at Netley in August 1871, after having passed through a course at the Army Medical School, Netley.

Order of merit and position	Studied at	No. of marks.
1. Cranston, A.	Edinburgh	5965
2. Brown, G. B.	Melbourne and Edinburgh	5775
3. Young, L. A.	Dublin	5335
4. MacGibbon, J. A.	Belfast	5320
5. Brown, J. M.	Cork	5150
6. Cherry, J. A.	Dublin	5060
7. Connelank, B.	Aberdeen	5040
8. Cass, J.	Glasgow	5005
9. Williamson, J. G.	London	4640
10. Ross, G. H.	London	4630
11. Farnham, W. J.	Dublin	4482
12. Jervis, H. W.	Dublin	4475
13. Spence, W. F.	London	4470
14. Leslie, D.	Glasgow	4342
15. Charlton, W. J.	Dublin	4310
16. Russell, J.	Aberdeen	4300
17. Arthur, A. H.	Aberdeen	4185
18. Tait, W.	Dublin	4170
19. Murray, G.	Belfast	4145
20. Murray, W. J.	Dublin	4100
21. Ferguson, P.	Cork	4055
22. Wilson, W. I.	Edinburgh and Aberdeen	4015
23. MacNab, J.	Cork	4014
24. Hamilton, R.	Dublin	3980
25. Wilson, J. B.	Sheffield, Edinb., and Glasgow	3880
26. Lewis, G. D. N.	London	3812
27. Murray, J. W.	Dublin	3812
28. Brown, F. H.	Dublin	3684
29. Gaultier, F. E. D.	Montreal and London	3677
30. O'Connell, M. D.	Cork	3645
31. Paterson, C. S. M.	Dublin	3550
32. Ward, J. C. P.	Dublin	3520
33. Fisher, W.	Dublin	3517
34. Buchanan, W. P.	Dublin	3514
35. Jervis, J. H.	Glasgow	3486
36. Jackson, J. P.	Edinburgh, Montreal, & London	3450

## MEDICAL VACANCIES.

The following vacancies are announced:—

ATCHAM UNION, Salop—Medical Officers for the St. Chad's and St. Mary's Districts.  
BARNLEY UNION, Yorkshire—Medical Officer for the Wombwell District.  
BOURNEMOUTH GENERAL DISPENSARY—Resident Surgeon.  
BRADFORD (Yorkshire) INFIRMARY and DISPENSARY—Physician.  
BRISTOL—Surgeon to the Police.  
BURY UNION, Lancashire—Medical Officer for the Tollington No. 1 District.  
CHESTER GENERAL INFIRMARY—Visiting Surgeon.  
COVENTRY PROVIDENT DISPENSARY—Surgeon.  
DERBYSHIRE GENERAL INFIRMARY, Derby—Resident Assistant House-Surgeon; Two Dental Surgeons; Non-Resident Dispenser.  
DEVIZES DISPENSARY, Wilts—Surgeon.  
DEVIZES UNION, Wilts—Medical Officer for District No. 1.  
DURHAM COUNTY HOSPITAL—Physician.  
FEENAGH and KILMEEDY, co. Limerick—Medical Attendant to the Royal Irish Constabulary.  
GLASGOW POLICE—Casualty Surgeon for the Central Division.  
GREAT EASTERN RAILWAY—Surgeon to the King's Lynn District.  
GREAT EASTERN RAILWAY PROVIDENT SOCIETY—Surgeon for the East Anglian District.  
GREAT NORTHERN RAILWAY—Surgeon for the Sutton Branch.  
HOLBORN UNION—Medical Officer for District No. 1.  
ISLINGTON—Medical Officer of Health.  
KING'S LYNN UNION, Norfolk—Medical Officer to the Workhouse and Infirmary.  
KING'S LYNN—Admiralty Surgeon and Agent for.  
MIDDLESEX HOSPITAL—Physician; Assistant-Surgeon.  
NEWCASTLE UNION, co. Limerick—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Feenagh Dispensary District.  
NORFOLK and NORWICH HOSPITAL—House-Surgeon.  
OMAGH UNION, co. Tyrone—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Eastern Division of the Omagh Dispensary District.  
QUEEN'S COLLEGE, Birmingham—Demonstrator of Anatomy.  
QUEEN'S HOSPITAL, Birmingham—Fourth Physician.  
ROYAL INFIRMARY, Bristol—Surgeon.  
ST. GILES and ST. GEORGE, Bloomsbury—Resident Assistant Medical Officer at the Workhouse.  
SETTLE UNION, Yorkshire—Medical Officers for the Horton and Settle Districts, and the Workhouse.  
SOUTHAMPTON UNION—Medical Officer for District No. 2.  
UNIVERSITY OF DURHAM—Medical Tutor at the Newcastle-upon-Tyne College of Medicine.  
UNST, Shetland—Parochial Medical Officer and Public Vaccinator.  
YORK UNION—Medical Officer and Public Vaccinator for District No. 4.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

LAW, W. T., M.R.C.S., appointed Resident Physician to the Royal Infirmary Edinburgh.  
POPE, H. Campbell, M.R.C.S., appointed House-Surgeon to the Seaman's Hospital, Greenwich.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

### BIRTH.

\*MARSHALL—On August 11th, at 16, Ardgowan Square, Greenock, the wife of Dr. W. J. Marshall, of a son.

### MARRIAGE.

\*ARGLES, Robert, M.R.C.S., of 8, Radnor Place, Gloucester Square, to Rose Eleanor, elder daughter of Edwin Lendon, Esq., of Maidstone, on Aug. 12th.

### DEATHS.

\*KENDALL, Thomas M., F.R.C.S., L.S.A., at King's Lynn, aged 51 years, on August 15th. No cards. Friends will please accept this intimation.  
\*MANN, Robert, Esq., Surgeon, at Plas Elmy, St. Asaph, North Wales, late of Manchester, on August 14th.

**BEQUESTS, DONATIONS, ETC.**—James Stewart Forbes, Esq., of Wimbledon, bequeathed £5000 each to the Brompton Hospital for Consumption, the Middlesex Hospital, University College Hospital, St. Mary's Hospital, and the Asylum for Idiots, Earlswood; and £1000 to the Hospital for Sick Children, Great Ormond Street.—"S. S. C." has given a second £1000 to the London Infirmary for Diseases of the Legs.—"Z. D. W." has given a second £1000 to the Westminster Hospital.—Mrs. F. H. has given £250 to the National Hospital for Consumption, Ventnor, viz., £50 for chapel fund, £100 for curate, and £100 for maintenance of necessitous Protestant clergymen.—The Weymouth Sanatorium has received £180 under the will of Mrs. Balston.—William Gater, Esq., of South Stoneham, bequeathed £100 each, duty free, to the Royal South Hants Infirmary, and the County Hospital, Winchester.—"A Friend" has given £200 towards paying off the mortgage on the Eye Hospital, Birmingham.—The General Hospital, Birmingham, has become entitled to £100 under the will of Benjamin Chandler, Esq.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.

**WEDNESDAY** ... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY** ... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.

**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY** ... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

## MEMORIAL OF THE LATE DR. TANNER.

We have been requested by Dr. Percy Boulton to publish the following circular:—

"It is proposed to perpetuate in some suitable way the memory of the late Dr. Thomas Hawkes Tanner. It is hoped that every one, whether patient, friend, or brother practitioner, who feels interested will subscribe; and in order to meet his poorer gratuitous patients, sums from One Shilling will be accepted. From the immense number of those who have expressed the deepest sorrow at the loss of a beloved friend, or physician, or feel a debt of gratitude for the boon which the late doctor had conferred on his brother practitioners by his printed works, it is hoped that a sufficiently large sum will be obtained to invest and produce interest to establish an Annual 'Tanner Scholarship,' to be competed for and awarded to the student most proficient in Diseases of Women, which was Dr. Tanner's specialty. It is hoped that this will give an impetus to a study which hitherto has not been made sufficiently prominent. Dr. Tanner was himself so desirous of doing every thing for the most possible good, that we feel that a memento of this kind is more suitable than any other monument that could be erected.

"Subscriptions can be paid to 'The Tanner Fund' at the London and Westminster Bank, Stratford Place, Oxford Street, where all cheques can be crossed; at any of the following Chemists, where Subscription Lists are opened: Cooper, 26, Oxford Street; Corby, 308, Oxford Street; Young and Postans, 35, Baker Street; or to

"Your obedient servant, PERCY BOULTON, M.D.  
6, Seymour Street, Portman Square.

## "Donations already Received."

	£	s.	d.
Madame Spiers, Ladbroke Grove.	20	0	0
Mr. Mills, Highgate	10	10	0
Mrs. A. Smith, Highgate	10	10	0
Mrs. P. Henderson, Gloucester Place	2	2	0
Miss Wilson, Highgate	1	1	0

"N.B.—It is requested that every one will try and interest others in the cause, and thus enable us to do justice to the memory of so great and good a man."

## DR. EDMUNDS AND THE REPORTED CASE OF CHOLERA.

SIR,—As you may need to make some comment upon the case of Cholera reported by me in the *Times* of Tuesday, I write to say that I shall be glad to show it to any gentleman from your office. I have written nothing but the short note in *Tuesday's Times*, and I am not responsible for the way in which the papers have placarded the subject. The case is one of true contagious cholera. Dr. Buchanan did not see the case until seven hours after the crisis had passed. He then urged that the bedding should be destroyed as soon as the patient could be shifted, and was more emphatic than I had been on the necessity for this. The ambiguous use of the word "sporadic" by Mr. Forster places me in a false and unfair position. Of course the case is a sporadic one, unless associated with an epidemic.

I am, etc., JAMES EDMUNDS.

4, Fitzroy Square, August 16th, 1871.

**ENQUIRER.**—The subject for the Collegial Triennial Prize is "The Structure and Functions of the Medulla Oblongata, including the Connections of the Central Nerve-Roots." The essay must be sent in before Christmas Day, 1873. The prize consists of the John Hunter medal executed in gold, to the value of fifty guineas, or at the option of the successful author of the dissertation, of the said medal executed in bronze, with an honorarium of fifty pounds. The Jacksonian Prize is the amount of the dividend (between ten and eleven pounds) received from the trust. The subject for the present year, 1871, is "The treatment of wounds after operations, including the arrest of hemorrhage primary and secondary." For the ensuing year, 1872, the subject is "Diseases of the nose, including those of the sinuses connected with it, and their treatment." The essay must be sent in before Christmas Day, 1871 and 1872 respectively.

DR. HARRIS (Redruth).—One or more will probably shortly appear; but we are unable to give any more definite answer.

D. (Liverpool).—Will our correspondent send the name of the paper, with the date, from which he obtained the cutting forwarded to this office? Our correspondent should forward his name, not necessarily for publication.

## SMALL-POX LET LOOSE.

SIR,—When the large fever "asylums" were being built, we were told that they would accommodate not only the severe cases of contagious fever, but also the more widely-infecting perambulating cases, so that an epidemic would be stamped out by isolation of those affected. How this idea is now carried out, the following example will show. A short time back, a girl applied to me with well-marked variola. The eruption on the face had been out two or three days, and was becoming pustular. She had been vaccinated—one slight mark; the constitutional symptoms had been slight, and she applied chiefly on account of the disfigurement. I had her sent to the Hampstead Hospital, and she was admitted.

A few days afterwards, I was called to attend a labour in the neighbourhood. To my surprise, the door was opened by this same girl—the eruption just desquamating. I asked if she had not been to the hospital? She said: Yes, she had been there two days, and was then discharged. The doctor told her that, "as she had been going about with the small pox so long, she might as well go about with it a little longer." Two wrongs do not make a right. Moreover, the stage of desquamation is the most dangerous as regards the spread of the disease.

At the time this patient was discharged, the published returns showed a large number of empty beds at this hospital.

I have lately lost two patients from small-pox after confinement; and it was no fault of the Hampstead authorities that I did not lose another.

London, August 14th, 1871.

I am, etc.,

PAROCHUS.

P.S.—Names and dates are at your service.

SANITAS writes to *The Borough of Marylebone Newspaper* regarding a complaint made by the *Pall Mall Gazette* to the effect that the efficient and early emptying of dust-bins is not properly carried out in London by the dust collectors. The *Pall Mall Gazette* argued that heavy penalties should be enforced if these contractors did not fulfil their contract properly. "Sanitas" believes that "the real culprits are lazy domestic servants and the dust collectors, who play into each others' hands. The employers of both are certainly not sufficiently vigilant in the matter. The nuisance could be at once done away with if householders would prohibit the practice by lazy servants of making the dustbin a receptacle for all kinds of decaying matter and other rubbish. If nothing but cinder-ash were permitted to be thrown in the dustbin, there would be no 'nuisance' at all. Cabbage-stalks, potato-peelings, fish-bones, and all such useless articles, could be burnt. These regulations should be enforced by the authorities, who should institute a house-to-house inspection and levy a fine in all cases of neglect; if this plan were carried out, we should hear no more of the dust-bin as a fever-nest and a propagator of cholera."

## CHOLERA: THE SECRETIONS IN COLLAPSE.

SIR,—While most of us are making up our minds as to what will be our treatment for the cholera, Sir Thomas Watson's *resumé* appears very opportunely. May I draw attention to that part which describes the defective oxidation that ensues during collapse in its effects on the urinary and biliary secretions, etc. In reference to this, I would bring to notice certain experiments of Dr. Polli and Dr. Ruspini, some twenty years since. The former, in a paper read before the Instituto Lombardo (1851), on the action of different gases on the contractility of the heart in frogs, makes several remarkable observations on the loss of contractility of the fibrin or clot when blood is received from the arm of a person bled into a bottle full of carbonic acid; it never froths or casts a scum, as under ordinary circumstances, with other differences. To be short, his reasoning leads him to the suggestion of peroxide of hydrogen for treatment of asphyxia from choke-damp. This hint was put to use in the following year by Dr. Ruspini (see *Asphyxia Traitée par l'Eau Oxygénée*; par M. Ruspini, *Journal de Chimie Médicale*, 1852, page 275), and with marked success. Five hundred grammes of the oxygenated water of Queneville which he had at hand, were divided into two portions. One heated so as to develop the gas was held in a flask to the mouth and nostrils; the remainder was given to the extent of seventy-five grammes, a spoonful at a time; at first it was rejected from the stomach, but the reaction of the vital powers was prompt, and the recovery was apparently due to the treatment. Hoping this may be worthy of attention, I am, etc.,

London, August 1871.

GEORGE GASKOIN.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, August 12th; The New York Medical Record, August 4th; The Boston Medical and Surgical Journal, August 4th; The Madras Mail, June 3rd; The Shield, August 12th; The Philadelphia Medical Times, July 27th; The Philadelphia Medical Independent, July 29th; The Birmingham Morning News, August 11th; The Courier, August 11th; The Cornish Telegraph, August 16th; etc.

Lee, Saltash-on-Tamar; The Secretary of the City of London Truss Society; Dr. Murray, London; Mr. George Gaskoin, London; Mr. E. Lund, Manchester; Dr. Wade, Birmingham; M.R.C.S. Eng.; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Dr. Dyce Duckworth, London; Mr. W. P. Swain, Devonport; Dr. Macnamara, Dublin; Dr. A. P. Stewart, London; Our Dublin Correspondent; Mr. Joseph May, Devonport; Dr. Robert Martin, Manchester; Mr. Berkeley Hill, London; Dr. Nankivell, Torquay; Dr. Elliot, Carlisle; Our Glasgow Correspondent; Dr. James Edmunds, London; Dr. Ogle, Derby; Mr. Manchester Correspondent; Mr. T. Watkin Williams, Birmingham; The Secretary of the Norfolk and Norwich Hospital; etc.

## University College, London.

—The Session of the FACULTY of MEDICINE will commence on Monday, October 2nd, 1871. Introductory Lecture at 3 p.m.

### LECTURES IN WINTER SESSION.

Medicine—Professor J. Russell Reynolds, M.D., F.R.S.  
Physiology and Pathology—Professor Burdon-Sanderson, M.D., F.R.S.

Anatomy and Physiology—Professor Sharpey, M.D., F.R.S.

Chemistry—Professor Williamson, F.R.S.

Anatomy—Professor G. V. Ellis.

Comparative Anatomy—Professor Grant, M.D., F.R.S.

Surgery—Professor Maudsley, F.R.S.

Practical Surgery—Mr. Berkeley Hill, M.B., F.R.C.S.; Mr. Christopher Heath, F.R.C.S.; Mr. Marcus Beck, M.S., M.B., F.R.C.S.

Dental Surgery—Mr. Ibbetson, F.R.C.S.

### LECTURES IN SUMMER SESSION.

Botany—Professor Oliver, F.R.S., F.L.S.

Midwifery—Professor Graily Hewitt, M.D.

Medical Jurisprudence—Professor Maudsley, M.D.

Practical Chemistry—Professor Williamson, F.R.S.

Mental Diseases—Lecturer, W. H. O. Sankey, M.D.

Hygiene and Public Health—Professor Corfield, M.A., M.B.

Maternal Medicine and Therapeutics—Professor Ringer, M.D.

Palaeontology—Professor Grant, M.D., F.R.S.

Operative Surgery—Mr. Christopher Heath, F.R.C.S.

Pathological Anatomy—Professor H. Charlton Bastian, M.D., F.R.S.

Ophthalmic Medicine and Surgery—Professor T. W. Jones, F.R.S.

Analytical Chemistry—Professor Williamson, throughout the Session.

## UNIVERSITY COLLEGE HOSPITAL.

Physicians—Sir W. Jenner, Bart., M.D., F.R.S. Dr. Reynolds, F.R.S., Dr. Wilson Fox, Dr. Ringer, Dr. H. Charlton Bastian, F.R.S.

Obstetric Physician—Dr. Graily Hewitt.

Physician to the Skin Infirmary—Dr. Tilbury Fox.

Assistant-Physician—Dr. F. T. Roberts, B.Sc.

Surgeons—Mr. Erichsen, Mr. Marshall, F.R.S., Sir Henry Thompson, Mr. Berkeley Hill, Mr. Christopher Heath.

Ophthalmic Surgeon—Mr. Wharton Jones, F.R.S.

Dental Surgery—Mr. Ibbetson.

### CLINICAL INSTRUCTION.

Medical Clinical Lectures by Prof. Sir Wm. Jenner, Prof. Reynolds, and Prof. Graily Hewitt; also by Dr. Wilson Fox, House-Physician of Clinical Medicine, who will read a paper on the Progress of the practical study of Medicine. Dr. Ringer, the Assistant Lecturer of Clinical Medicine, also gives a special instruction in the method of the post-mortem examination of clinical cases.

Practical Clinical Lectures by Mr. Erichsen, House-Physician of Clinical Surgery, Professor Marshall, and Mr. Henry Thompson.

Lectures on Ophthalmic Cases by Mr. Wharton Jones. Clinical Lectures on Diseases of the Skin by Dr. Tilbury Fox.

Practical Clinical Lectures by Mr. Christopher Heath.

Practical Clinical Lectures by Mr. Marcus Beck.

Practical Clinical Lectures by Mr. Ibbetson.

Practical Clinical Lectures by Mr. Ringer.

Practical Clinical Lectures by Mr. Marshall.

Practical Clinical Lectures by Mr. Erichsen.

Practical Clinical Lectures by Mr. Thompson.

Practical Clinical Lectures by Mr. Hill.

Practical Clinical Lectures by Mr. Heath.

Practical Clinical Lectures by Mr. Jones.

Practical Clinical Lectures by Mr. Roberts.

Practical Clinical Lectures by Mr. Fox.

Practical Clinical Lectures by Mr. Bastian.

Practical Clinical Lectures by Mr. Grant.

Practical Clinical Lectures by Mr. Oliver.

Practical Clinical Lectures by Mr. Ellis.

Practical Clinical Lectures by Mr. Williamson.

Practical Clinical Lectures by Mr. Sharpey.

Practical Clinical Lectures by Mr. Maudsley.

Practical Clinical Lectures by Mr. Grant.

Practical Clinical Lectures by Mr. Oliver.

Practical Clinical Lectures by Mr. Ellis.

Practical Clinical Lectures by Mr. Williamson.

Practical Clinical Lectures by Mr. Sharpey.

Practical Clinical Lectures by Mr. Maudsley.

Practical Clinical Lectures by Mr. Grant.

Practical Clinical Lectures by Mr. Oliver.

Practical Clinical Lectures by Mr. Ellis.

Practical Clinical Lectures by Mr. Williamson.

Practical Clinical Lectures by Mr. Sharpey.

Practical Clinical Lectures by Mr. Maudsley.

Practical Clinical Lectures by Mr. Grant.

Practical Clinical Lectures by Mr. Oliver.

Practical Clinical Lectures by Mr. Ellis.

Practical Clinical Lectures by Mr. Williamson.

## Middlesex Hospital.—The

WINTER SESSION for 1870-71 will be opened on Monday, October 2nd, at Three o'clock, with an Introductory Address by Dr. JOHN MURRAY.

### LECTURES FOR WINTER TERM.

Medicine—Dr. Greenhow, F.R.S. Surgery—Mr. De Morgan, F.R.S. Practical Surgery—Mr. Hulke, F.R.S.; Mr. Lawson; Mr. Henry Morris, Physiology—Mr. Lowne. Anatomy—Dr. R. Liveing, M.A. Cantab.

Chemistry—Mr. Heisch. Pathological Anatomy—Dr. Cayley. Anatomical Demonstrations—Dr. Liveing.

Cable Tutor—Dr. Liveing.

Consulting Physicians—Dr. F. Hawkins; Dr. A. P. Stewart.

Physicians—Dr. Goodfellow; Dr. Thompson; Dr. Greenhow, F.R.S.

Obstetric Physician—Dr. J. Hall Davis.

Assistant-Physicians—Dr. R. Liveing, M.A. Cantab.; Dr. Cayley; Dr. John Murray.

Consulting Surgeon—Mr. Shaw.

Surgeons—Mr. De Morgan, F.R.S.; Mr. Nunn; Mr. Hulke, F.R.S.

Ophthalmic Surgeon—Mr. Hulke, F.R.S.

Assistant-Surgeon—Mr. Lawson.

Dental Surgeon—Mr. Tomes, F.R.S.

Assistant Dental Surgeon—Mr. Turner.

The Hospital contains 305 beds; there are special departments for Cancer (36 beds), for Diseases of the Eye, Diseases of Women and Children, and Syphilis.

Demonstrations are given during the Summer Session on Diseases of the Skin and the Use of the Laryngoscope.

Three Clinical Prizes, including the Governors' Prize of twenty guineas, are awarded to those students who pass the most satisfactory examination at the bedside and in the post mortem room.

Class Prizes are also given. There are likewise valuable rewards in the form of Six Resident Clinical Appointments. Students can avail themselves, free of charge, of the assistance of the College Tutor, and thus avoid, when preparing for the examinations of the Licensing Boards, the necessity of any private teaching apart from that of the Medical School.

General Fee for attendance on the Hospital Practice and Lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries, £90, which may be paid by instalments.

Fee for Dental Students, 25 guineas for the first year, and 15 guineas for the second.

One of the members of the staff receives Students to board with him.

Further information may be obtained on application to the Treasurer, Dr. GREENHOW; the Dean, Dr. CAYLEY; or to Mr. LUCAS, the Resident Medical Officer, at the Hospital.

General Fee for attendance on the Hospital Practice and Lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries, £90, which may be paid by instalments.

Fee for Dental Students, 25 guineas for the first year, and 15 guineas for the second.

One of the members of the staff receives Students to board with him.

Further information may be obtained on application to the Treasurer, Dr. GREENHOW; the Dean, Dr. CAYLEY; or to Mr. LUCAS, the Resident Medical Officer, at the Hospital.

General Fee for attendance on the Hospital Practice and Lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries, £90, which may be paid by instalments.

Fee for Dental Students, 25 guineas for the first year, and 15 guineas for the second.

One of the members of the staff receives Students to board with him.

Further information may be obtained on application to the Treasurer, Dr. GREENHOW; the Dean, Dr. CAYLEY; or to Mr. LUCAS, the Resident Medical Officer, at the Hospital.

General Fee for attendance on the Hospital Practice and Lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries, £90, which may be paid by instalments.

## Westminster Hospital

### MEDICAL SCHOOL.

The WINTER SESSION will commence on Monday, October 2nd, when an Introductory Address will be delivered by Dr. BASHAM.

After the Address a Conversazione will be held in the Board Room.

The Hospital contains 101 beds, and has a special Ward for the Diseases of Women.

In addition to the Practice of the Hospital, Matriculated Students are admitted to the Practice of the Royal Westminster Ophthalmic Hospital, and to that of the National Hospital for Paralysis and Epilepsy.

Clinical Instruction is given daily in the Wards and by Weekly Clinical Lectures, and Pupils are required to serve in rotation as Clinical Assistants, they are also called upon from time to time to undertake the examination of Patients at the bedside in the presence of the Teacher.

In the Out-Patients' department, where more than 28,000 persons are seen annually, the Pupils are practised in physical diagnosis, in the use of the various instruments employed in Medicine and Surgery, in the minor operations, and the method of interrogating patients. Frequent examinations are held on each of the subjects taught, with the view to test the progress of each student.

The House-Physician and House-Surgeon and Resident Obstetric Assistant are appointed from among the senior students by examination without the payment of any fee, and they are provided with board and lodging free of expense. A Medical and Surgical Registrar have each a salary of about £50.

In addition to the Prizes awarded to the best students of each year, there is a Scholarship of 20 guineas in Anatomy and Physiology; a Prize of similar value for General Proficiency; and two Clinical Prizes of the value of five guineas each for the best kept Records of Cases in the Hospital on the Medical and Surgical sides respectively.

The entire Course of Study may be attended on payment of either 70 pounds in one sum, or of 35 pounds, 30 pounds, and 10 pounds at the commencement of the first, second, and third years respectively. Terms for shorter periods are mentioned in the Prospectus.

Arrangements have been made with some of the Clergy and Medical Gentlemen in the neighbourhood (which is now one of the healthiest and most desirable in London) to receive students to reside with them.

Full information upon all subjects connected with the School can be obtained from the Dean of the School, or the Secretary of the Hospital. The Prospectus will be sent to any address.

OCTAVIUS STURGES, M.D.,

Dean of the School.

Westminster Hospital, 10th August, 1871.

## Vaccine Lymph, preserved in

Glycerine, in Glass Tubes, 1s. each, or three for 2s. 6d. Fresh Points every Thursday, 2s. 6d. per doz.

Apply to Dr. WOODWARD, Public Vaccinator, Worcester.

Amsterdam Exhibition, 1869.—The Grand Diploma of Honour:

Being the First Prize, and Superior to the Gold Medal.

Liebig Company's Extract of

MEAT.—Paris Exhibition, 1867—Two Gold Medals; Havre Exhibition, 1868—The Gold Medal.

Only sort warranted perfect and genuine by BARON LIEBIG, the Inventor.—"A success and a boon."

Medical Press and Circular. One pint of delicious beef tea for 2d., which costs 1s., if made from fresh meat. Cheapest and finest flavoured "stock" for soups, etc.

CAUTION.—Require BARON LIEBIG's signature upon every jar. Sold by all Indian Warehousemen, Grocers, Chemists, and Ship's Store Dealers.

All Wholesale Houses. And of LIEBIG'S EXTRACT OF MEAT COMPANY (Limited), 43, Mark Lane, E.C.

NOTICE.—Various chemical analyses have been published purporting to show a fraction more of moisture to exist in the Company's Extract than in some imitation sorts. It is extremely easy to evaporate the water added to any extent; but it is quite as certain that the fine meaty flavour which distinguishes the Company's Extract from all others would be destroyed, if the concentration of the Extract were carried beyond a certain degree. Best tea, made from Liebig Company's Extract with boiling hot water, will be found to be greatly superior in flavour, strength, and economy, to any other made. This explains the universal preference it obtains in the market.

This Extract is supplied to the British, French, Prussian, Russian, and other Governments.

## Tasteless Pills.—Cox's Patent.

Surgeons and Chemists supplied with an excellent Aperient Pill (the formula for which will be forwarded), covered with a thin non-metallic film, rendering each pill perfectly tasteless, at 1s. 6d. a gross. Postage ad.

They present an elegant pearl-like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving in a short time, even in cold water.

Any formula dispensed and covered, and samples, with a list of pills, from 200 formulae which are kept in stock, forwarded free on application.

Now ready, a strong leather-covered Pill Case, resembling a pocket-book, filled with Tasteless Pills (nearly 7 gross), from 14 daily used formulae, sent on receipt of remittance for £1 1s. Empty, 10s.

Cox, Son, and Co., Tasteless Pill Manufacturers, Brighton.

Salmon's Obstetric Binder,

## ADDRESS IN SURGERY,

DELIVERED AT

THE THIRTY-NINTH ANNUAL MEETING OF THE  
BRITISH MEDICAL ASSOCIATION,*Held in PLYMOUTH, August 8th, 9th, 10th, and 11th, 1871.*

By JOSEPH LISTER, F.R.S.,

Regius Professor of Clinical Surgery in the University of Edinburgh; etc.

MR. PRESIDENT AND FELLOW-ASSOCIATES,—My duty on the present occasion is to endeavour, if possible, to give you an address commensurate in interest with the very high honour of being selected to deliver it. With this object, instead of attempting a general review of surgery, which has been presented under various aspects by my able predecessors, I have concluded to bring before you a subject which, though in some respects a special one, is calculated, as I believe, to revolutionise almost every department of surgical practice; I mean the antiseptic system of treatment. The fact that my name is associated with this topic tended to make me shrink from such a course; but, on the other hand, I could not but feel that this very circumstance has led in all probability to my standing before you to-day, so that you might naturally expect to hear something from me on this subject, while it is at the same time my sincere conviction that I could not turn the present occasion to better account than by exciting in you a keener interest in the antiseptic system than it has yet elicited, and by placing you more in a position to diffuse its benefits among mankind.

Among the causes which have hitherto interfered with the general acceptance of this mode of treatment, by far the most prejudicial is the doubt of its fundamental principle, instilled by various authors who have opposed the germ-theory of putrefaction, and who, supposing themselves to be advocating the cause of truth, have not only, as it appears to me, espoused the side of error, but have unconsciously inflicted an amount of material evil upon their fellow-creatures such as mere speculative opinion is seldom able to produce. For few medical men in active practice have the leisure to sift and weigh the facts and arguments of such a discussion; yet, if they lose firm faith in the guiding principle of the treatment, the attainment of a full measure of success becomes with them a matter of impossibility. "Felix qui potuit rerum cognoscere causas" was never more applicable than here.

Another great cause of failure, and consequently of dissatisfaction with the system, is the want of practical initiation into the treatment. For, greatly as our means of carrying out the principle have improved of late, both in simplicity and in efficiency, mere description seems inadequate to convey a clear idea of the method of employing them. Hence, while there are now scattered up and down in this country and in various other parts of the world, gentlemen who, having witnessed the treatment in our wards, whether as students or as qualified practitioners, are attaining exactly the same kind of results as we do, success seems a rare exception for any who have not had such opportunities.

I propose, therefore, in the first place to bring shortly under your notice some considerations relating to the theoretical basis of the treatment; secondly, to exhibit before you the chief means that we now employ, and, so far as this can be done upon a table, the mode of using them; and lastly, by your permission, to state some facts which I hope you may regard as sufficient evidence that, by such means employed on such a principle, we have it in our power to obtain easily and securely results of a kind that without antiseptic management the surgeon would not be justified in aiming at.

With regard to the theory of the treatment, I propose to avoid all doubtful disputations, and simply bring before you a few facts, to which I invite your earnest attention and your candid judgment.

Those of which I have first to speak have reference to the well known experiment of Pasteur of boiling a putrescible liquid in a flask with an attenuated and contorted neck. It is now nearly four years since I introduced portions of the same specimen of urine into four glass flasks, so as to make each about one-third full, and, after washing their necks, drew them out with a spirit-lamp into tubes less than a line in diameter, and then bent three of them at various acute angles, while the fourth was left short and vertical, though equally narrow. Each flask was then boiled for five minutes, the steam issuing freely from the orifice; after which they were left with the ends of the necks still open, so that air might pass in and out freely in obedience to the condensation and expansion caused by the diurnal changes of temperature. The boiling, I need hardly say, was for the purpose of killing any organisms contained in the liquid or adhering to the sides of the glass; the bending of the necks in three of the flasks was with the view of intercepting particles of dust, which, according to the germ-theory, are the cause of putrefaction, as distinguished from the atmospheric gases; while the fourth neck was left short and vertical for the sake of contrast, to afford opportunity for dust to fall into the liquid, where such portions of it as had the nature of living organisms might propagate and induce in the fluid any changes of which they were capable. The result was, that in the vessel with short and upright neck two different kinds of fungi, visible to the naked eye, soon made their appearance, and these grew steadily till they had attained large dimensions, the liquid meanwhile gradually changing from its pale straw colour to a deep amber tint, implying alteration in its chemical constitution. But in the flasks with bent necks the fluid remains to this day entirely unaltered.\* I regret that the distance from Edinburgh to Plymouth is too great to permit me to bring these objects before you. One perilous journey they have already had, when I took them from Glasgow to Edinburgh nearly two years ago, nursing them carefully during the railway journey, to the amusement of my fellow-travellers; and in the drive from the station to my house the violent rocking of the vehicle churned up their contents till the upper part of the body of each flask was full of a frothy mixture of the putrescible liquid with the atmospheric gases; yet no harm resulted, and the fluid in the bent flasks still retains its original pellucid clearness and pale hue. Bringing these in imagination before you, as represented in this diagram, consider what these facts imply. Let us not push them one tittle beyond their inevitable interpretation. The drops of moisture deposited in the bent tubes from condensation of the steam when the lamp was removed dried up in a few days, so that the necks have been for nearly four years open and dry from end to end. Comparing the capacity of the part of the body of the flask containing air with that of the narrow neck, it is manifest that a considerable portion of fresh air has passed into the flask every night, in consequence of the fall of the temperature, a corresponding portion passing out again by day, though not the same which entered; for the diffusion of gases would ensure its mixing freely with that previously present. Hence, during nearly four years this putrescible liquid, this boiled urine, has been freely exposed to the influence of the atmospheric gases, yet it has not putrefied. About half a year after the commencement of the experiment, I decanted a little of the liquid from one of the bent flasks into a wineglass, and found it sweet in odour and faintly acid to test-paper, while an honest search with a powerful glass failed to detect even the minutest organism. Covering the glass to prevent evaporation, I found it in two days stinking, while under the microscope it already teemed with various organisms, and a few days later it showed fungi to the naked eye. Thus the fluid was demonstrated to be still putrescible and a favourable nidus for organic development; yet both these changes have been prevented for nearly four years by the circumstance that the air, in gaining access to it, had to pass through a narrow bent tube of clean dry glass. Now such

\* Some minute shining crystals have of late been deposited on the bottom of the flasks, probably from condensation through the very slow evaporation constantly going on.

a tube could not by possibility arrest any atmospheric gas. It cannot possibly have stopped anything but the atmospheric dust. It follows, therefore, not as a matter of theory, but as an inevitable inference from fact, or, in other words, as a truth, that, so far as this particular instance of a putrescible liquid is concerned, both the development of such organisms as the microscope enables us to detect, and the concomitant putrefactive changes, are occasioned by particles of dust suspended in the atmosphere, but not by the atmospheric gases. I confess, Mr. President, I am ready to blush for the character of our profession for scientific accuracy when I see the loose comments sometimes made upon this experiment; and I am tempted to doubt whether some of the commentators can have enjoyed the advantages of sufficient education either in chemical physics or in logic. The simplicity and perfect conclusiveness of the experiment constitute its great charm, and render it, as it appears to me, deserving of your careful consideration. Yet, having before published an account of it, although nearly two years have since elapsed, so as to add considerably to its weight, I do not know that I should have felt justified in bringing it forward on the present occasion, if I have not an additional fact to communicate respecting it besides the results of further lapse of time. We have seen that we have been forced to the conclusion that, though the gases of the air certainly pass into the body of the flask and out again every twenty-four hours, its dust, even though of extreme minuteness, must be arrested by the contorted tube. Now, inevitable as this inference is, it will be satisfactory to have it converted into the position of an observed fact. This Professor Tyndall's simple but beautiful mode of investigation with a condensed beam of light has lately enabled me to do. Having prepared two dry glass flasks, one of them having the neck drawn out and contorted, I arranged them, through the kind assistance of my colleague Professor Tait, so that the body of each was pierced by a beam of highly condensed sunlight in an otherwise dark apartment. The beam, scattered by the floating particles of dust, showed white in the surrounding darkness, within the flasks as well as without, proving that the air within the flasks was dusty like that outside. I now closed with sealing-wax the orifice of the unvented flask, and, leaving the other open, allowed both to remain undisturbed in the laboratory. A fortnight later I again submitted them to the solar beam, condensed as before, and now found that in both flasks alike the visible part of the beam terminated abruptly at the glass on each side, showing that in both the air was, as Tyndall expresses it, "optically empty," or, in other words, that it was destitute of even such minute particles of floating matter as could produce the faintest nebulosity. During the time between the two observations, the force of gravity had led to the subsidence of even the minutest floating particles; and, though the changing temperature of the laboratory had of necessity induced the daily entrance of air into the open flask, the bent form and fine calibre of the tube by which it was admitted had effectually filtered it of suspended material, though in a very dusty apartment.

The other class of facts in this division of the subject to which I am anxious to direct your special attention was also suggested by one of Tyndall's experiments with the condensed luminous beam—that, namely, in which he proved the perfect manner in which cotton-wool filters the air of its suspended particles, by blowing against the beam with a pair of bellows having a mass of the cotton tied over the nozzle; the result being that the beam, elsewhere white from illuminated dust, became perfectly black at the part on which the current was directed through the cotton filter; hence the idea naturally suggested itself that cotton-wool might be used with advantage as an antiseptic dressing.\* Of course it would be useless to apply ordinary cotton without special precautions; for, according to the germ-theory, putrefactive particles must exist among the fibres and

lie scattered over the wool. But if the cotton were impregnated with some volatile material capable of destroying the vitality of the septic organisms, and then placed upon the wound after washing it with a lotion containing the same substance in solution, the result ought to be, supposing the theory true, that, after the volatile antiseptic had become dissipated by diffusion from the dressing and from the wound, the cotton-wool, though destitute of any chemically antiseptic properties, should effectually prevent, by its filtering property, the access of any putrefactive agents, and keep the wound sweet, while in itself a perfectly bland and unstimulating application. Accordingly I prepared four samples of cotton-wool by diffusing through each one of the following substances—chlorine gas, sulphurous acid gas, carbolic acid vapour, and the vapour of benzine—four materials very dissimilar in chemical properties, but having a common hostility to low forms of life. Chlorine, sulphurous acid, and carbolic acid, are well known to have such a property; and, knowing that benzine is used by the entomologist for killing insects, and having ascertained by experiment the potency of its vapour for the destruction of pediculi, I thought it probable that it would also answer our purpose. I then dressed with these four kinds of prepared cotton-wool various suppurating sores, excoriations, and contused wounds, after washing the surface with the corresponding lotion, or in the case of benzine, with the undiluted material. The results in every instance corresponded exactly with theory. After about twenty-four hours' exposure at the temperature of the body, the cotton-wool was found to have lost the odour of the antiseptic, yet the blood, serum, or pus, as the case might be, remained perfectly sweet for an indefinite period, while healing advanced in the satisfactory manner that might be anticipated from the absence of all irritating quality in the dressings. There was, however, one circumstance, highly instructive in itself, which interfered sadly with the utility of this application; namely, that, if the discharge happened to be sufficiently copious to soak through the cotton-wool and appear at its external surface, putrefaction occurred throughout the entire mass of the moistened part down to the wound, even within the first twenty-four hours after the dressing, if the fluid were sufficiently copious to penetrate within that period. It is only when dry that cotton-wool can arrest the progress of microscopic organisms, which have ample room to develop among its meshes when filled with a putrescible liquid.

And now, gentlemen, allow me, at the risk of seeming tedious, to endeavour to bring home to you a little more closely the inference that is to be drawn from these facts. But, first, let me describe in detail the manner in which the dressing with carbolised cotton-wool was practised. The cotton-wool having been impregnated with about a two-hundredth part of its weight of the acid in the form of vapour, the surface of a granulating sore or abrasion was washed, together with a portion of the surrounding skin, with a solution of the acid in about forty parts of water. A piece of oiled silk of the size of the sore was then applied, to prevent the dressings from sticking through dryness. Over this was placed a piece of folded linen rag, rather larger than the oiled silk, and impregnated with the carbolic acid vapour in the same manner as the cotton-wool; the object of the rag being to absorb the discharge and prevent it from trickling down, as it was otherwise apt to do, below the slightly absorbent cotton, involving its early appearance at the surface and consequent spread of putrefaction to the wound. Lastly, a well overlapping mass of the carbolised cotton-wool was securely fixed by a bandage. The result, as before stated, was that, though all chemical antiseptic virtue left the dressing within a day or two, putrefaction was excluded by the cotton-wool for any length of time, provided the discharge did not penetrate to the exterior of the mass. Consider, now, the circumstances of the serum or pus that oozed from beneath the edges of the oiled silk into the folded rag—let us suppose a week after the application of the dressing, when all traces of the volatile antiseptic had certainly disappeared. Here was a highly putrescible liquid, not subjected to boiling, as in the flask experiment, or acted on by any chemical agent whatever, yet remaining free from putrefaction in a rag moistened with it at the temperature of the

\* Mr. Alfred F. Munnich, of the London School, who attended Tyndall's first lecture on "Dust and Disease," has since written to Professor Tyndall, stating he had been greatly interested with the subject, and had made some experiments following the experiments, and stating that he had found that cotton-wool might be used to arrest the entrance of putrefactive particles from wounds—a suggestion which I at once proceeded to act upon in the above described manner.

human body, simply because it was covered over with pure dry cotton-wool. How, then, did this cotton-wool exclude the causes of putrefaction in the atmosphere? It certainly did not keep out any of the atmospheric gases. The same cause that led to the escape of the volatile antiseptic necessarily occasioned a perpetual intermingling between the external air and that between the meshes of the fabric, as any one acquainted with Graham's beautiful researches into the laws of gaseous diffusion must at once admit. The only constituent of the atmosphere which the cotton-wool could possibly exclude is its dust; and this we know, from Tyndall's experiment, it did exclude. Here, then, we have another inevitable inference from fact, another truth, and that in itself all-sufficient, with reference to the antiseptic system of treatment; the truth, namely, that pus, blood, and the dead tissues in contused wounds do not putrefy through the influence of the atmospheric gases, but through the operation of particles of dust, which may be permanently deprived of septic energy by the vapour of an agent like carbolic acid. I do not ask you to believe that the septic particles are organisms. That they are self-propagating, like living beings, and that their energy is extinguished by precisely the same agencies as extinguish vitality, such as heat and the various chemical substances to which I have referred, is certain, and is of the utmost practical importance. But if any one, in spite of these facts, and in spite of the strong analogy of the yeast-plant, and the various kinds of fungi which we term mould, prefer to believe that the septic particles are not alive, and to regard the vibrios invariably present in putrefying pus or sloughs as mere accidental concomitants of putrefaction, or the results, not the causes, of the change, with such an one I, as a practical surgeon, do not wish to quarrel. Nor do I enter upon the question whether spontaneous generation can take place at the present day upon the surface of our globe. To do this, would be to engage in doubtful disputations which I promised to avoid.

But I do venture earnestly to beg of all of you who are engaged in surgical practice, that you will give these simple facts your careful consideration; and if you think the interpretation I have given a sound one, do not let any statements, whether in books or in journals, shake your belief in the truth that putrefaction, under atmospheric influence, as it occurs in surgical practice, is due to particles of dust ever present in the atmosphere that surrounds our patients, and endowed with wonderful chemical energy and power of self-propagation, yet happily readily deprived of energy by various agents which may be employed for the purpose without inflicting serious injury upon the human tissues. With this as your guiding principle, you will find yourselves successful with the antiseptic system of treatment; but without it, whatever theory you adopt, you will ever be walking in the dark, and therefore ever liable to stumble.

And now I proceed to the second division of my subject—the exhibition of our principal means and methods of treatment. For preventing the access of putrefactive fermentation, the agent which we now commonly use is what we have termed the antiseptic gauze, of which these are samples—being a loose cotton fabric, the fibres of which are impregnated with carbolic acid securely lodged in insoluble resin, which holds the carbolic acid with remarkable tenacity, while at the same time a little paraffin is added to prevent the adhesiveness which the mixture of carbolic acid and resin would otherwise possess. The interstices between the fibres are kept free from these ingredients, so that the fabric, being porous, may be fitted for absorbing discharges. The carbolic acid is in considerable quantity in the gauze; but it is held so tenaciously by the resin that, on the one hand, when first applied, it is unirritating to the human skin, and, on the other hand, unless discharge be very copious, it will retain its virtues for upwards of a week at the temperature of the human body. Now supposing I were going to use this gauze for dressing any case in which a copious discharge was expected—as, for example, a large psoas abscess immediately after it had been opened—I should take a considerable quantity of the gauze (about as much as one can conveniently hold between the extended hands) and fold it three times so as to make it eight layers. But there would be no use in my having

the folded gauze of this extent, if I did not adopt some means for compelling the discharge to pass throughout the length and breadth of the dressing; and for this purpose some impermeable tissue must be interposed between it and the external air. That which we have found the most convenient is a cheap and light form of mackintosh, termed "hat-lining" by the India-rubber dealers. I cut a piece of this, nearly as large as the folded gauze, and then place it beneath the layer that is intended to be outward. The discharge then coming from the wound, situated opposite the middle of the gauze, instead of passing directly outwards through it, is compelled to traverse all the extent of the antiseptic dressing; and in that way, by using a sufficiently large piece, and with this arrangement of the mackintosh, you may be perfectly certain that, if you leave no putrefactive mischief in a wound or abscess, none will enter it, however profuse the discharge may be during the first twenty-four hours. That is one very important point gained. As the discharge diminishes, the intervals between the dressings are extended; and when it amounts to only a minim or two in twenty-four hours, the application may be left undisturbed for a week. The gauze is also extremely convenient in the form of bandage—an antiseptic bandage—which is put on to hold the main dressing in position; and instead of being a nidus for putrefaction, as a cotton-bandage would be, it increases at every turn the antiseptic efficacy of the dressing. Besides this, the bandage having a degree of stickiness, its turns do not tend to slip as those of a cotton-bandage do, which is an additional advantage.

Such, then, are the means by which, in ordinary cases, we ensure that putrefactive fermentation does not extend from without into the wound or abscess. Of course it would be of no use to apply such an external dressing if putrefactive particles in an active state were left within a wound. If a wound be presented for treatment, having been inflicted by another than the surgeon, some dust is sure to have been introduced; and we must first destroy its septic energy by washing the raw surface thoroughly with some liquid trustworthy for the purpose, such as chlorine-water, or sulphurous acid lotion, or a strong solution of carbolic acid, or of chloride of aluminium, for there are various preparations which may be used with efficiency. But when the surgeon operates on a previously unbroken integument, he has the opportunity of preventing the septic particles from entering in an active state at all, by operating in an antiseptic atmosphere. This is readily provided for in small operations by using a watery solution of carbolic acid with Richardson's apparatus for local anæsthesia. For making the spray more fine, I have found it convenient to have the lower end of the water-tube almost entirely stopped up, leaving only very minute apertures. The result is, as you see, an exceedingly satisfactory spray. For any small operation this answers the purpose perfectly well, provided always that you take the precaution of having the liquid filtered through a cambric handkerchief or some similar fabric, in order to exclude the grosser particles of dust, which otherwise would have the effect of blocking up the fine orifice at the nozzle of the apparatus—an occurrence which, under some circumstances, might be disastrous in its effect.

We have lately found that the strength of the solution employed for producing the spray may be considerably reduced. We have ascertained that it may be used as weak as one part of carbolic acid to a hundred parts of water; and that a spray made with such a lotion is thoroughly trustworthy as an antiseptic atmosphere.

The reduction of the strength of the spray is a matter of great importance. In the first place, it is a great comfort to the surgeon, as I can testify from experience. When we used a solution as strong as one part of carbolic acid to forty parts of water, my hands were constantly in a rough and uncomfortable state; but when the proportion is reduced to one to a hundred for the production of the spray, the hands experience no inconvenience whatever, and one can even breathe with comfort in such an atmosphere.

In the second place, it is equally advantageous for the patient, because the weaker the antiseptic application, of whatever sort it is, the less irritation do we occasion to the tissues of the

part treated with it. The antiseptic is always injurious in its own action; a necessary evil, incurred to attain a greater good. To suppose that it is useful by its own operation in some specific manner unknown to us, is an entire mistake. I know that, not only from theory, but as a matter of experience. At one time, I used the undiluted acid; and, in doing this, I could not avoid producing not merely irritation, but a certain amount of sloughing. Then I used a strong solution of carbolic acid in oil; then a rather strong solution in water; then a weaker watery lotion; and now we employ a solution as weak as that which I have described—one part of carbolic acid in a hundred of water—and that applied only in the form of spray, avoiding absolute drenching of the tissues at all, and avoiding also the injection of the wound by a syringe, as we used to do after the operation was completed, in order to destroy the organisms introduced; and, in direct proportion to the weakness of the solution used and to the smallness of its opportunity of acting on the tissues of the part, is the satisfactoriness of the results obtained, provided that the essential object of avoiding putrefaction is secured.

And now, supposing that I were, single-handed, about to change the dressing in the case to which I have alluded—a large psoas abscess—the spray is of extreme value. I wish that the spray shall play upon the surface of the body, in the angle between the dressing and the skin, as I lift the gauze. It would be very inconvenient if it were necessary for this purpose always to have an assistant to work the spray; but, by a little management, the spray can be worked perfectly well, as you see, by the surgeon himself. [This is done by placing the bottle of Richardson's apparatus against the ball of the thumb, and holding the India-rubber bulb to be compressed between the opposite side of the bottle and the fingers of the same hand.] Supposing this were the site of the incision in a case of psoas abscess, as long as I choose I can perfectly protect it with the antiseptic atmosphere, and then put on what we have called, for the sake of distinction, a "guard"—a piece of rag dipped in the one to one hundred watery solution of carbolic acid, after which the spray can be removed with security; the surrounding parts having then been cleansed from any discharge there may be, the spray is once more made to play on the part during the exposure of the wound until the permanent antiseptic dressing is re-applied.

But, gentlemen, though such a spray-producer is perfectly efficacious for a small operation, it does not make a cloud of sufficient volume for a large one, such as an amputation of the thigh or at the hip-joint. Therefore, with the object of securing the same result in such cases, I have had this apparatus prepared, which, I confess, is in a cumbrous and heavy form; but I hope it will be improved in that respect before long. Meanwhile, it is much better than nothing. Let me say a word or two, in the first place, as to the principle on which it is constructed. It appears that the best kind of spray which can be produced, is that which is formed on the principle of the atmospheric odorator, by having one tube set at right angles to another, the air-tube being larger than the water-tube, and the opening of the water-tube being exactly opposite the middle of the orifice of the air-tube. This makes the finest and best of all sprays. But, with a heavy apparatus like this, it would never do to have to move it about along with the nozzle, as is absolutely necessary in the instruments of ordinary construction on this principle. We must have tubes to convey the air and the water to a considerable distance; and this is very easily done by not merely having the liquid ejected by the force of the air blown over the orifice of the water-tube, but by having it driven through the tube by the force of the same pump that propels the air, the quantity of the water being regulated by a stop-cock. Then it was necessary to provide some ready means of clearing the fine end of the water-tube, in case of its obstruction by particles of dust. This is done by having the water-tube straight for a short distance from the nozzle, and then bent at a right angle, with a little milled cap to screw on at the angle, so that, in case of obstruction, the cap is screwed off, and the orifice of the water-tube is cleared at once with a needle or a bit of fine

wire. I have used this apparatus in various operations of late, among which I may mention my two last amputations, one in the thigh, the other in the arm, in both cases using nothing stronger than the one to a hundred solution for the spray, and the same for the sponges; except only, what I believe to be a wise precaution, that, when a sponge has become soaked with blood, it should be washed first with pure water, then dipped for a moment in a strong solution (one to forty), and then squeezed out of a solution of one to a hundred to give it the necessary blandness; and in both these cases putrefaction was entirely avoided. [The apparatus exhibited had two nozzles, attached to independent caoutchouc tubes, furnishing large clouds of spray, that could be directed, if necessary, to opposite sides of the part operated on. Two of Richardson's spray-producers, worked by two assistants, will answer the same purpose, though less efficiently.]

The antiseptic catgut-ligature is used for securing the arteries while the spray still plays over the wound. It is absolutely necessary that it should be properly prepared. I must not enter into the method of preparation, further than to say that catgut undergoes a remarkable change in its physical constitution when steeped for a long time in an emulsion of water and oil, so that it becomes quite transparent, and no longer liable to become soft and slippery when placed in water or in a watery discharge. But for this circumstance, the animal ligature would be an impossibility; but, if you use it properly prepared, you will, I believe, see good reason to be satisfied with it. That which I now show is extremely fine, much finer than any silk commonly employed; and yet with a piece like this I should not hesitate to tie the femoral artery in a stump. If you choose to use it thicker for a large vessel, you can do so. It is conveniently carried on a little winder, in a capsule appended to a caustic case. The catgut, as tied in the ordinary reef-knot with the ends cut short, seems to me to be a perfect hæmostatic. It has all the simplicity and universal applicability of the ligature, with, at the same time, the virtual absence of any foreign body from the wound. If putrefaction be avoided, it is rapidly absorbed, and you may reckon as certainly on the absence of any interference with primary union on the part of such ligatures, as if there were no ligatures at all. Should putrefaction occur, I was at first uneasy lest the prepared catgut might soften and permit hæmorrhage. I was, therefore, at the pains to test some of the prepared catgut in the following manner. I tied some pieces of it at intervals round a cylinder of India-rubber, so as to pinch the India-rubber to a considerable degree of constriction, and then introduced it into putrid serum of blood, and kept it for a week at a temperature of about 90 deg. At the end of this period, the India-rubber was still constricted, shewing that the catgut had retained its hold in the putrid liquid, in spite of the constant strain of the elastic material upon the knots. No doubt, in such parts of a wound as actually putrefy, the little bits of catgut must come away like shreds or sloughs of cellular tissue; but I am bound to add that this is only a matter of presumption: for, although I have used nothing but this ligature for securing vessels in wounds for more than two years, excepting torsion, which I comparatively rarely resort to, and though in certain classes of cases putrefaction cannot be avoided, in no instance have I seen the catgut knot come away, nor have I ever known secondary hæmorrhage or abscess caused by its use.

I have spoken of the injury that the stimulating carbolic acid lotion inflicts on the tissues by irritation. The great disadvantage of this is, that it causes an unusually large flow of serum during the first twenty-four hours or more; and you must provide a special exit for the serum, else you will have inconvenience from tension, which will lead to suppuration, though not of the putrefactive kind. For the purpose of guarding against this, I introduce, at the most dependent part of the wound, a strip of lint steeped in a solution of carbolic acid in about ten parts of olive oil, to serve as a "drain". This is drawn out under the spray in twenty-four or forty-eight hours. If you drew it out without providing an antiseptic atmosphere, you would certainly have putrefaction. In some cases, a fine

drainage-tube is convenient for this purpose, if well steeped in solution of carbolic acid. For, as India-rubber happily absorbs carbolic acid, the drainage-tube is antiseptic when introduced.

There is yet one other point to which I must allude, which is, that carbolic acid interferes with the cicatrisation of a wound, if it act directly on it. This agent operates with special energy on the epidermis. Sometimes this is a convenience. For example, if we dip the forefinger into a carbolic acid lotion, and hold it there for a second or two, we may be certain that the epidermis is so imbued with the carbolic acid, that it is for the time antiseptic, and therefore may be introduced into the cavity of an abscess or any other part which we wish to explore; and very valuable an antiseptic forefinger often is in that way. But this action of the acid on the epidermis makes it interfere with cicatrisation; and even the gauze, though generally perfectly free from irritating influence upon the sound skin or an old scar, will frequently, if applied directly to a wound, entirely arrest new epidermic formation, and sometimes excoriate a tender young cicatrix. Something, therefore, must be interposed to protect the wound from this effect of the antiseptic. What we have generally used hitherto for this purpose is what we have called the "oiled silk protective", consisting of oiled silk varnished with copal varnish, which makes it much less permeable to the carbolic acid. But, unfortunately, this is not a perfect protective. It acts admirably until it becomes moistened; but afterwards the water that penetrates the substance conveys the carbolic acid in. I have striven in various ways to get something perfect in that way; and I have lately been engaged in a manner which, though not yet completely successful, may be mentioned on account of its interest otherwise. Some time since, I tried the effect of an oil-paint on oiled silk, in the hope that the particles of pigment, closely packed, might serve considerably to intercept the carbolic acid, though the oily material that cements the particles is permeable to it. The result was such as I had hoped, except that the material proved too stiff for convenient use. A few weeks since, however, I happened to be going through an India-rubber factory, and there I saw, among other things, the process of mixing various pigments with caoutchouc; and it occurred to me, might not India-rubber, blended with some pigment, answer as a protective? The India-rubber is permeable to the carbolic acid; but with the pigment it might not be so. I first tried a coloured rubber that had been vulcanised, and then came out a most curious and interesting circumstance. The sulphur in the vulcanised India-rubber acting chemically on the discharge, the result was a stench like rotten eggs, presenting an excellent example of decomposition without putrefaction; for there was no putrefactive fermentation—no spread of the decomposition into the interior of the wound or abscess. It was limited to the exterior, and was simply the result of the chemical action of the nascent sulphur upon the discharges. And if, under such circumstances, we resumed the oiled silk protective, we again had perfect absence of unpleasant smell.

The necessity for avoiding any sulphur in the material was a great cause of embarrassment; for, as a general rule, the admixture of any foreign ingredient with caoutchouc causes a most inconvenient softness and adhesiveness of the product—evils which vulcanising completely corrects. Magnesia forms an exception to this rule, producing with the pure rubber a very satisfactory substance as regards its physical properties. But then we found that, in the case of a sensitive skin, this magnesia caoutchouc produced intolerable itching and redness, for a reason which I do not quite understand. At length it occurred to me that perhaps shell-lac, which seems quite un-irritating, might be mixed with the caoutchouc; and that this might answer the purpose. For though shell-lac, when once mixed with carbolic acid, holds it very tenaciously, as is seen in the lac plaster with which some of you are familiar, yet the acid does not readily penetrate into unmixed lac. When I suggested this to the managers of the India-rubber works,\*

\* I cannot but publicly express my thanks to the managers of the North British India-rubber Works, for the great kindness and liberality with which they have carried out these experiments for me.

they told me that they had previously ascertained that shell-lac could be perfectly blended with caoutchouc; the product being the beautiful article you now see, sufficiently tough, yet pliant, transparent, and with no unpleasant odour, and, as I ascertained by experiment, practically impermeable to carbolic acid. Here, then, I thought I had attained the object at which I had been aiming for years; and already we were getting results of a kind we had never got before: we had reached more nearly than ever before the conditions which we know must occur subcutaneously. I had never witnessed the healing of ulcers proceed so rapidly as I have seen it under this protective, covered with overlapping gauze; but, to my extreme chagrin, I have learnt within the last few days that, in two patients with very sensitive skins, even this material produces a trifling irritation. Still I cannot but believe that we are on the verge of getting what we want in a protective—viz., a tissue perfectly bland and unstimulating in its own substance, and also quite impermeable to the antiseptic.

So much, then, gentlemen, as to our means; and now, if you will allow me a little time longer, I will tell you what I expect will be the most interesting to you all—the history of some cases illustrative of the effects of this treatment.

The simplest of all cases for antiseptic management is that of abscess; and the most beautiful, as it seems to me, in the results. It is the simplest, because here we do not apply the antiseptic to the part concerned at all; we only open the abscess in an antiseptic atmosphere by free incision, pressing out the pus—ensuring, in short, free exit for the contents, without the possibility of the entrance of putrefaction. The antiseptic never enters the abscess-cavity at all; and I would beg of those who still hold the view that carbolic acid exerts its beneficial influence by acting upon the tissues of the part, to consider carefully the case of abscess—say a psoas abscess connected with diseased vertebræ. Under the carbolic acid spray, a free incision is made into the cavity; and I may remark that the spray is of peculiar value for this purpose, because, if an artery happen to be divided during the dissection, it can be secured without any difficulty, or it can be tied after the abscess has been opened. As we used to proceed, plunging in a knife, and effecting the opening at one stroke, if a deep vessel were divided, it was a matter of very great inconvenience. Suppose now a large psoas abscess has been opened under the antiseptic spray by free incision, we press out the pus—letting out, it may be, a quart or more; and on the following day we find, if we have emptied the abscess thoroughly, that there is not a drop of pus to be pressed out, and no pus is formed from that abscess for the future. This is a thing that must be seen to be believed. It seems so contrary to one's experience, and yet it is exactly in accordance with pathological theory. Now suppose a few more days have passed, probably nothing whatever can be squeezed from the abscess-cavity; but, if you can squeeze out a drop of anything, it is a drop of clear serum—clear, transparent serum. Hence, Mr. President, I say it is transparently clear that the carbolic acid does not enter into the abscess-cavity at all. Still less, if possible, can it penetrate to the diseased bone of the vertebræ; because, if the carbolic acid did enter in even a slight degree into the abscess-cavity, it would produce opacity of the serum, from coagulating its albumen. Therefore the clear drop which you press out is certain proof that the carbolic acid does not act on the affected part at all.

I have here a piece of bone which came out along with the pus from a large psoas abscess which I opened in April last—a portion of cancellated bone. I must not hand it round, because it is precious, and one similar piece has already been lost through injudicious exhibition. But you, Mr. President, can see that this is cancellated bone, proving that the abscess really did communicate with the diseased vertebræ. The patient was an adult, with an acute curvature of the dorsal region of the spine, and other symptoms of spinal disease. He had a sense of painful constriction round the waist, pain shooting down into the haunches and lower limbs; and he was in a state of very great general prostration. Still, if we had not

seen these bits of bone, it might have been said by anybody, and perhaps fairly said, "I do not choose to believe that this abscess was connected with diseased bone; it may have been concomitant with acute spinal symptoms, without being in connexion with the vertebræ." But the discharge of the bone with the pus makes us sure on this point. Well, in that case the patient experienced immediate relief from his distressing symptoms, without the occurrence of the slightest febrile disturbance; and there has been no discharge of pus since the evacuation of the original contents, though up to the present time there has been still an oozing of serous fluid into the gauze, which is changed once every four or five days. Four months, you may say, is a long time for the treatment to have continued. No doubt it is so; but what is the alternative? The alternative, as we all know, either if the abscess be opened by free incision or allowed to open itself, is almost invariably death, either after an acute course of irritative fever, which we should all wish to prevent, or after a long period of protracted hectic, perhaps even more distressing. Meanwhile, the serous discharge in this case has been steadily diminishing; and I have reason to believe, from previous experience, that we shall ultimately obtain a cure.

Among other cases of this kind, I may mention one as peculiarly instructive. On January 20th, 1870, I opened a psoas abscess in a man twenty-seven years old, who from the age of eleven had had antero-posterior curvature in the upper dorsal region of the spine. At length a psoas abscess made its appearance, and, increasing slowly, extended far down into the thigh. I evacuated between fifty and sixty ounces of thick pus, with lumps of curdy material, and several small pieces of cancellated bone and numerous other osseous particles came out in subsequent dressings. My friend Dr. Hector Cameron (the case being a Glasgow one) undertook the after-management, continuing the antiseptic dressing, and changing it, when the serous discharge became slight, every four or five days—the lac plaster being used; and at length, on the 5th of February last, it was perfectly healed. Then, after giving the spine a few weeks' more rest (for I believe, after such an abscess has completely healed, you ought still to give the spine repose for a while, just as you would in a case of spinal disease without abscess), that patient perfectly recovered, and is now walking about, a healthy man. Here patience and perseverance, continued for more than a year, were at length rewarded by success.

In connexion with these cases of abscess, there is a curious circumstance with respect to which I must put you on your guard; that is, that sometimes the discharge, serous though it is, soaking into the gauze, comes to stink in the dressing, in the same sort of way as pus stinks when acted upon by the vulcanised India-rubber, though with a different quality in the smell. Why this is, I do not know. It seems that it is not the carbolic acid only that occasions the chemical change, for we never had such an occurrence when we used the lac plaster. Whether it may be the resin in the gauze, I do not know; but certain it is that you often have some smell; and sometimes, instead of being merely a faint odour of rotten hay or bad soap, it is exceedingly fetid. A few days before I left Edinburgh, I opened, in a little sickly, dwindled child, a conjoined psoas and lumbar abscess, associated with spinal disease. I emptied the extensive cavity by free incision in the lumbar part, and dressed with the gauze. Two or three days afterwards, on approaching the bed, I perceived a strong smell; and, on taking off the dressings, the stench was very great. As this was the first case in which I had ever opened a psoas abscess with the 1 to 100 spray, and as I had seen regurgitation of the spray take place during the operation, I confess I was alarmed at this foul smell; but it so happened that I could squeeze out a very little fluid from the interior; and, taking it away under the spray, and diffusing it upon a plate, so as to be able to estimate accurately any odour it might have, I found that it was perfectly free from smell. Just as in the pus under the vulcanised caoutchouc protective, there was decomposition occasioned by the chemical action of the dressing, but no putrefactive fer-

mentation; for that would necessarily have spread into the interior. We took the course of dispensing with the mackintosh among the gauze, because my house-surgeon, Mr. Bishop, has noticed that, if the mackintosh be removed so as to allow free escape for the gaseous products of decomposition, you do not get nearly so much smell; but, if the mackintosh be dispensed with, you must use a greater thickness of the gauze, and dress daily. This was done; and, within a week of the opening of the abscess, the discharge was only a few minims of serum *per diem*, and the boy had already picked up wonderfully in general health.

Ligature of arteries in their continuity presents one of the most striking illustrations of the advantages of antiseptic treatment. I have only had two opportunities, since I published on the subject, for applying the catgut in this way; both of them were cases of popliteal aneurism, and both were formidable from having become diffuse. One of them was in a man aged 47, who had only noticed the aneurism for five weeks, during which time it had been rapidly on the increase, so that the patient observed a change in its dimensions every day. On his admission into hospital, August 31st, 1869, it reached from the upper part of the ham to the top of the lower third of the femur. At the same time it caused extreme pain, with numbness in the limb, and the knee was bent at a right angle. I tied the femoral artery at once with a stout piece of prepared catgut, cutting the ends close to the knot, and the result was that within ten days the wound was a superficial sore bridged over with cicatrix, which afterwards healed like an ordinary narrow ulcer. There was a remarkable contrast in one particular in the treatment of this case compared with ordinary cases. Instead of leaving the patient to lie with his limb constantly in one position on a pillow until the time should have elapsed for the ligature to separate by suppuration—there being no separation to take place, and, as I believed, no source of irritation present—I from the first began free movement of the limb, and at a very early period got the knee extended, to the very great advantage of the patient. I remember a precisely similar case in which I tied the vessel with silk in the ordinary way some years ago, where the patient was not able to straighten the knee for weeks after leaving the hospital; and in fact I do not know that he is able to do so now.

The other case was much more remarkable. The patient, also aged 47, but looking more like 67, presented himself at the hospital last summer with a diffuse popliteal aneurism which had run an acute course, but already extended some way up the thigh. I urged him to come at once into the hospital. He said he had important business to attend to, and could not do so. He came back a fortnight later with the aneurism grown to enormous dimensions laterally, and extending up to the junction of the middle and upper thirds of the thigh. At the same time, partly from hæmorrhage into its own body, and partly from being worn out with the pain he endured, he was reduced to an extreme degree, so that one of the surgeons of our hospital remarked, "He is a dying man at any rate." In his case, also, the knee was flexed; there was much numbness and œdema in the foot, and no pulsation in either tibial artery. Under such circumstances what was to be done? To open into this enormous mass by the old operation would be most unpromising. To amputate would, I felt sure, be to kill the man outright. The only alternative was to tie the artery. Considering the extent to which the huge mass had already interfered with the circulation, it seemed extremely probable that such a procedure would be followed by gangrene. Still it seemed to afford the only chance. Then the next question was, Where should it be tied? The lower down, the further from the heart, the better, if it could be safely done. But was there any choice? Was not the external iliac the only practicable site? The only part remaining in the thigh was what I believe is rightly regarded as a forbidden region, from the vicinity of the profunda or other considerable branches. Yet having ascertained, by experiment, that an antiseptic catgut-ligature does not weaken the artery at all, and does not make secondary hæmorrhage likely to occur under such circumstances, I felt justified in putting on the liga-

ture in this forbidden region. It is an extremely striking fact, if we think of it, that after a large arterial trunk has been tied, we never have hæmorrhage on the second or third or fourth day—never practically during the first week we may say. The external coat, pinched in by the ligature, is always strong enough to resist the impetus of the blood, however near the ligature may be to a branch, till the tissue has undergone alteration, till it has become softened by the granulating process through the irritating influence of the septic ligature. But if the ligature be not septic, nor in any other respect irritating, there is nothing to weaken the external coat. Why should it be weakened? On the contrary, as experiment has shown in one instance, the catgut itself, becoming replaced by living tissue, acts as a strengthening ring instead of making the vessel weaker. Hence I felt justified in applying it as near as possible to the aneurismal tumour, though this was just about the most frequent place of origin of the profunda. Catgut a good deal thicker than that which I have shown was used, the ends being of course cut short, and all went well. There was no appearance of suppuration from the vicinity of the ligature, and the enormous mass gradually became absorbed. Being much emaciated, the man put on fat so fast that we were deceived at first with respect to the diminution of the coagulated blood, which was actually going on much more rapidly than we inferred from our measurements. Ultimately all that great mass disappeared, and the patient, first hobbling with crutches, then walking with a stick, is now a hale man; using no stick at all. I should add that in the performance of the operation, though I cut down higher up than the apparent upward limit of the aneurism, when I divided the deep fascia I found that the extravasated blood extended further than the swelling, so that I cut into the coagula of the aneurism. What would, in all probability, have been the result of such a procedure without antiseptic treatment?

Mr. President, I have hitherto felt some hesitation in publishing cases of this kind, lest I should lead my professional brethren to do that which would only end in disaster. An eminent London surgeon wrote to me some time ago asking for catgut, as he wished to use it for tying the external iliac. I wrote back to him saying that if he did not feel sure he could avoid putrefaction in the wound, I would not advise him to use catgut, because, if the wound should putrefy, the catgut lying there, without any means of withdrawing it, would perhaps lead to unhealthy ulceration and so occasion secondary hæmorrhage, as happened in a case of Sir Philip Crampton's; which was of course not treated antiseptically. But with the spray I feel that, in operations of this sort, safety is a matter of certainty. Any one of you who chooses may, I believe, tie the femoral artery with no more danger than in making a cut in the skin on the hand; and with much less danger than making a cut in the skin on the hand without antiseptic treatment in an ordinary hospital.

The catgut ligature has other applications of such interest, that I must beg you to listen to some cases in illustration of them. Those to which I wish to refer are two of irreducible hernia, which failed to yield to the treatment which Mr. Syme long advocated, that of keeping the patient lying on his back, giving a spare diet, with frequent doses of castor-oil, and daily application of the taxis. One was a ventral hernia in a young woman, originating apparently in deep seated abscess of the abdominal wall. It was of large size, causing extreme inconvenience, and the treatment to which I have referred having failed, I laid the sac freely open so as to expose the adherent intestines and omentum which it contained, and separated the adhesions under the comparatively inconvenient antiseptic means which we then used, freely sponging with 1 to 40 watery solution of carbolic acid, and protecting such portions of the viscera as were not being immediately operated on by a cloth dipped in the lotion. When the adhesions had been all detached, by tearing or by the knife, I reduced the viscera under the antiseptic cloth as under a substitute integument, and then pared the edges of the orifice by which the sac communicated with the abdominal cavity [an oval aperture about three inches long], cutting off the peritoneum from the muscular and fibrous structures, and then stitched those edges securely with closely applied

interrupted sutures of prepared catgut, the ends being cut off near the reef-knots. The external wound was then stitched and treated antiseptically like an ordinary one. During the introduction of the deep stitches, the patient vomited violently, so that it was only by exerting very firm pressure that I prevented further visceral protrusion, and after going back to bed she vomited again—a tremendous test for our catgut stitches; but they stood the test. The young woman left the hospital without any hernia; and though a very small protrusion did afterwards appear below one part of the cicatrix, it was readily reducible and amenable to ordinary treatment by means of a truss.

The other case was a large umbilical hernia in a cook. It interfered with her duties very much, and at last she could hardly walk about at all. This case was treated like the last; but, in the absence of the spray, if I had known what I was about to encounter, I should not have entered upon it. It was a most laborious and protracted business, dividing very complicated intestinal adhesions by cutting and tearing, and at the same time maintaining constant vigilance in protecting the exposed intestines with the antiseptic cloths. The thing, however, was at length accomplished, and the entire mass was returned into the abdomen. The edges of the deep opening were pared and sewn together closely with catgut sutures with their ends cut short, and the external wound was closed with carbolised silk stitches, leaving an opening for a "drain." A large quantity of blood happened to become effused into the sac during the first twenty-four hours, so as to reproduce the appearance of tumour, though not in sufficient amount to cause tension, and this made the absence of putrefaction and suppuration all the more striking. And now occurred a most unhappy circumstance, though at the same time instructive. The patient, who, as I afterwards learnt, had before been liable to temporary attacks of mental alienation, became, I fear, permanently mad, and a week after the operation she was up and walking about the ward, certainly testing the catgut stitches most severely, yet without any bad result. When the wound had healed, she was taken to a lunatic-asylum; and I have not been able to hear of her later than six weeks afterwards, when she left for another institution of the same kind; but up to that period there had been no return of hernia. Thus, you see, the catgut-stitch becomes a new engine in surgery, enabling us to attach deeply seated parts to each other, leaving the connecting medium to be removed by absorption.

As another striking illustration of antiseptic treatment, hitherto unpublished, I may mention a case of ununited fracture of the neck of the thigh-bone. The patient was a fine powerful man, 45 years of age, who had fallen down from a cart, and broken the neck of the femur. He had been treated in hospital elsewhere; but, strange to say, according to his own statement, he was turned out of that institution in five weeks on crutches, whereas he ought surely to have had at least six weeks with the long splint; and eighteen months afterwards he applied to me. There were all the ordinary symptoms of an ununited fracture of the neck of the femur. There was shortening to the extent of an inch and an eighth, while the trochanter was correspondingly nearer to the iliac crest than on the other side, and, instead of moving in the arc of a circle on rotation of the limb, turned on its own axis with a crunching sensation. The man could not raise his leg beyond a trifling degree, or turn round, as he lay, without supporting the trochanteric region with his hand; and he could rest no weight whatever upon the limb. Under ordinary treatment, this man would have been condemned to a life of hopeless uselessness. But, considering his time of life, there could be little doubt that the fracture was extracapsular, and that, if the ends of the fragments could be brought into the condition of a recent fracture, there would be union under proper treatment, if the man survived. But to effect this would involve making a free external wound, and, for aught I could tell, opening into the capsule of the hip-joint. And would that be a justifiable procedure? Thinking the matter over, although our antiseptic means were then comparatively imperfect, I believed I could operate so as to avoid putrefaction; and I felt sure that if putrefaction did

not occur, the procedure would be free from danger. Well, if I believed that I could do it with safety, and that it would probably have the effect of restoring the man to usefulness, it became my duty to do it; and I resolved to make the attempt. Accordingly, on December 2nd, 1868, the patient having been put under chloroform, I first moved the extended limb in all directions with the utmost freedom, so as to break down adhesions, which gave way with a report that could be heard all over the operating theatre. Then I applied the pulleys, and practised extension to the utmost degree that appeared justifiable, in order to draw down the lower fragments; and, the patient being placed on the sound side, with the pulleys still in operation, I cut down above the trochanter with a free longitudinal incision, the knife being smeared with a solution of carbolic acid, in four parts of olive oil, which was also continually poured into the wound—a very inconvenient mode when compared with the spray. At length, having cut down to a sufficient depth, I found, to my joy, that the tip of my finger, dipped, of course, in the oil, could be passed between the fragments, the ends of which, though irregular, felt smooth, as if covered with cartilage. I now took a gouge dipped in the oil, and roughened the edge of each fragment, producing abundance of bone-chips. I did not think it worth while to take out the chips; because, supposing putrefaction avoided, I expected the chips to be absorbed. A large piece of lac-plaster was then applied as an external dressing; and, while the pulleys were still acting, a long splint was put on very firmly, with iron bars substituted for the wood opposite to the seat of operation, to permit access for dressing. A few hours later, my house-surgeon came to tell me that there was serious bleeding. I went at once, and found that such was, indeed, the case, the blood having gone through the patient's bed, and made a pool on the floor. Without disturbing the splint, I carefully removed the dressings, and proceeded to plug the wound with long strips of lint dipped in the solution of carbolic acid in oil, feeling sure that, as there had been no material bleeding at the operation, plugging would be sufficient; and, as I pushed these plugs home, with my fingers dipped in the oil, and felt the mass of clotted blood, with the multitude of osseous fragments among it, I almost wondered at my own hardihood in making voluntarily a compound comminuted fracture of the neck of the femur. For it is one thing to do as Mr. Cresswell, whom I see before me, did with such striking success three years ago, to treat antiseptically an existing compound comminuted fracture of the neck of the femur—and that remarkable case, resulting from gunshot wound, ought, I think, to have attracted more attention than it did (see *Lancet*, Aug. 29, 1868)—but it is quite another thing to produce such an injury voluntarily. However, the wound was stuffed, thoroughly filled, about a dozen strips of lint, an inch broad and fifteen inches long, being employed; and the hæmorrhage being thus arrested, lac-plaster was re-applied. Next day I extracted the lint, in an antiseptic atmosphere produced by the best means then at our disposal, viz., under a large cloth steeped in the strong oily solution, beneath which dressing-forceps was insinuated, and with perfectly satisfactory result. No bleeding occurred afterwards; the coagula in the wound gradually became organised; nothing more was seen of the chips of bone, except two minute, partially absorbed, spicula, which appeared at long periods; and, not to enter into needless details, that man, when last I heard of him, was walking about with an useful limb, with only three-eighths of an inch of shortening.

The freedom with which joints may be opened in an antiseptic atmosphere, followed up with antiseptic dressing, is among the most striking and valuable circumstances of this treatment. One of my earliest cases of this kind was a large loose cartilage in the knee-joint, about an inch and a half long by three-quarters of an inch broad—not a favourable subject for the ingenious and excellent method of treatment of Mr. Square of this town. I cut down freely on the loose cartilage, having carbolic acid and oil dropped on the wound. I then fixed a sharp hook in its substance; and, producing an antiseptic atmosphere, as in the last case, by covering the part

with a cloth dipped in the oil, so as to prevent mischief from resulting from the regurgitation of air into the joint, hooked it out. I have since had another somewhat similar case. In both instances, I left the wound communicating with the knee-joint open, to allow free exit of the discharges; and no disturbance of the articulation took place. With the spray, the direct operation would be perfectly simple, as well as safe. As we can thus open joints without any mischief, we have the opportunity, in case of disease, of making free incisions before suppuration has occurred; and this treatment I have found to be extremely valuable in preventing suppuration and avoiding amputation or excision. Among several such cases may be mentioned one of disease of the wrist in a middle-aged woman who was admitted into the Edinburgh Infirmary in July of last year, suffering extreme pain night and day. Suppuration appearing imminent, and the case having resisted ordinary treatment, I made a free incision antiseptically down upon the carpal bones and the wrist-joint, cutting in the angle between the tendons of the indicator and extensor secundi internodii pollicis. During the following night, the pain was altogether absent; and, antiseptic dressing along with perfect rest being continued, the wound soon became superficial, without any suppuration of the joint; and she left the hospital retaining her hand in perfect soundness.

Partial excision of a joint, so unsatisfactory when practised for caries with sinuses,\* may sometimes be performed with great advantage when suppuration has not occurred, or when the pus has been evacuated antiseptically. An instance of this occurred in my practice last spring, in a man fifty-seven years of age, with an obstinate and painful disease of the wrist affecting the whole articulation, but especially the end of the ulna, which was extremely thickened. I cut down under the spray and nipped off the end of the ulna with bone pliers, and found the cartilage rough and eroded, though without suppuration. The wound was left open at its central part, with a drain of lint soaked with an oily solution maintaining a free communication with the joint, yet healing took place without the formation of a drop of pus. The man was discharged with a strong useful hand, but came back a few weeks afterwards, not on account of recurrence of the disease, but because he had fallen from a haystack when he was at work and broken the radius of the same arm.

Senile gangrene is, I suspect, a disease, the treatment of which must undergo a complete change through the antiseptic system. Amputation in such cases is now generally prohibited on account of the great probability of sloughing of the stump. But what is the reason of this risk of sloughing? The cause of the original gangrene is generally interference with the arterial circulation. But that interference is only sufficient to produce actual death at one spot where the disease begins, and it generally spreads by inflammation. Now dead tissues do not cause inflammation of themselves, any more than a bit of catgut does. Inflammation occurs because the dead part putrefies, and the parts in the vicinity, being weak, die from inflammatory mortification. If that be true, supposing we were to amputate and avoid putrefaction in the stump, who is to say but that sloughing, instead of being the rule, might prove the exception? while even such sloughs as might occur, if kept from putrefying, should be limited to the extent to which the operation might interfere with the vascular supply. Having long entertained these views, I was prepared to put them in practice in the following case.

A year ago, a woman above sixty years of age came into the hospital with her little toe affected with black discoloration, which had commenced at its tip and gradually extended to its base, and she was suffering constant acute agony. After carefully washing the surrounding skin with an antiseptic lotion—for that is absolutely essential in such a case—I amputated the

\* When an operation is performed in a part affected with sinuses, the presence of putrefaction in such tissues renders the case unsuitable, of course, for antiseptic management, as described in the text. For a special mode of dealing with such cases, the reader is referred to the article "Amputation", in *Holmes's System of Surgery*, second edition, vol. v.

toe within an eighth of an inch of the black part and dressed antiseptically. The result was that the wound healed without the slightest inflammatory disturbance; but the weakness of the tissues was indicated by the circumstance that a little bit of skin, about the twentieth of an inch in breadth, sloughed at the margin of one of the flaps, and a small piece of subcutaneous tissue also came away. Further, after a year's respite, her proclivity to the disease has been shown within the last few days by its reappearance in the tips of all the remaining toes of that foot, though the scar of the operation remains sound.

Though I regret to find that I have already greatly exceeded my allotted time, I must ask you to allow me to say a word or two regarding the treatment of ulcers under the gauze and protective. When shielded alike from the irritation of putrefaction and that of the antiseptic, ulcers heal which would otherwise refuse to do so. Last winter I had under my care in the Infirmary a young man who had burnt his foot very severely four years previously by treading in molten metal, some of which ran down into his boot. The large sore that resulted had been prevented from healing completely in consequence of the shrinking of the scar, which reached from some distance up the leg along the outer part of the dorsum of the foot to the toes, of which the outermost had been so much retracted that it pointed backwards, the end of the metatarsal bone being the most prominent part. A surgeon of considerable eminence had advised amputation of the foot, and he was afterwards under my care for five months in the Glasgow Infirmary, though without any good result; and at length, not wishing to submit to amputation, he came to me for a certificate of incompetency for any active occupation. I admitted him for the purpose of trying skin-grafting; but this failed, fortunately, as it turned out, for the illustration of this branch of the subject; for, having got the putrefaction present on admission completely arrested by strong antiseptic lotions, directly applied, and afterwards using nothing stronger than one of carbolic acid to four hundred of water as a lotion, and so making the dressing as little irritating as possible, healing went on in the most steady and beautiful manner under the gauze and protective, changed once in four or five days, and the man has now a thoroughly useful foot. I do not know that any result we have obtained has given me more pleasure than this.

When I first applied antiseptic treatment to ulcers, I did not aim at better results as regards rapidity of healing than those obtained by water-dressing. The object which I first had in view was merely to keep the atmosphere of our wards clear from the contamination occasioned even by healthy sores, if their discharges be allowed to putrefy. And the effects of this rigid antiseptic management upon the hospital atmosphere forms one of the most important features of the treatment. Last evening I learnt from one of the surgeons of a large Liverpool hospital the gratifying news that pyæmia has almost, if not entirely, left wards that were very subject to it before; and this, as far as can be ascertained by the surgeons, from no other cause than the careful carrying out of antiseptic treatment. The results of my own experience in this matter in Glasgow were published nearly two years ago; and I may repeat now what I then said, that wards once among the most unhealthy in the kingdom were converted into models of healthiness, simply as the result of antiseptic treatment. A year ago I published equally satisfactory evidence regarding my practice in the Edinburgh Infirmary for nearly a year. Another year has since elapsed, and during the whole of my Edinburgh period—now almost two years—in wards containing nearly sixty beds, we have not had a solitary case of pyæmia, whilst we are also entirely free from hospital gangrene and from erysipelas. Yet in those wards the beds are placed much closer than is in accordance with modern notions. At first I had them thinned; but learning that patients were placed on "shake-downs" for the night, and finding that, in spite of this arrangement, which of course was the same in effect as if all had beds, the wards remained perfectly healthy, I had the number restored to its original figure. Now I was myself at one time house-surgeon in those same wards for a year and a quarter, and I need hardly say that the surgeon under

whose care they used to be was a man under whom things were managed as well as they could be with the means then at a surgeon's disposal—I allude to Mr. Syme; yet I may safely say that such complete immunity from hospital-diseases never existed in those wards before the antiseptic system was introduced.

Nor has such testimony been borne by myself alone. Professor Saxtorph of Copenhagen, in a letter which I communicated to the *Lancet* a year since, published most striking information as to a very large hospital previously extremely liable to pyæmia, so that the smallest wounds often gave rise to it, yet remaining for a year absolutely free from the disease, and, so far as he could judge, from no other circumstance than the rigorous adoption of the antiseptic system. Equally satisfactory evidence regarding the healthiness of hospital wards brought about by this means has been given in one of the Blue Books of the navy by Dr. Bernard of the Naval Hospital here.

After statements of this conclusive character have been published regarding what is generally admitted to be the most urgent medical question of the day, when I consider the apathy with which they have been received in many quarters, I cannot avoid being reminded of the language of Macbeth—

"Can such things be,  
And overcome us like a summer's cloud,  
Without our special wonder?"

Mr. President, before I sit down, I must make an apology for the large share which my own performances have had in this address. For this defect I crave your kind indulgence, and only beg you to believe that I am actuated by other than selfish motives. For sure I am that, however much the means of carrying out the antiseptic principle may come to vary from those which we now use, the principle itself will certainly be ultimately recognised as the most important of all those that shall guide the practice of surgery; and the sooner our profession is aware of this, the better will it be for suffering humanity.

## AN ADDRESS

DELIVERED AT THE OPENING OF

### THE SECTION OF PUBLIC MEDICINE,

*At the Annual Meeting of the British Medical Association,  
in Plymouth, August 1871.*

By A. P. STEWART, M.D., F.R.C.P.,  
President of the Section.

GENTLEMEN,—The objects and aims of preventive medicine are now beginning to occupy a fair share of the public attention. The second chapter of *Ginx's Baby*—whose gifted author I am proud to call my friend, and once had for my fellow-worker—is an illustration of this statement, and is in itself a most instructive and admirable summary of the sanitary question. That second chapter—which is full of useful and suggestive thought mingled with much pleasant wit, and gives evidence of minute personal acquaintance with the homes and habits of the poor—leads us to infer that when an author like Edward Jenkins takes this matter up, and places it in the forefront of a work which counts its readers by tens of thousands, it is now at length beginning to assume its proper place and proportions in the public eye. Let me now offer a few remarks on some of the most noteworthy events that have taken place since we met at Newcastle, in connection both with the proceedings of the Public Medicine Section there, and with the contents of the programme now before us. And for clearness' sake, let me arrange my thoughts under these four heads:—

1. The results of individual effort;
2. The results of Associational effort;
3. The proceedings of the Legislature; and
4. A few concluding words on the moral and religious aspects of our subject.

1. Preventive medicine furnishes no exception to the general rule, that much—very much—of what is most important both in scientific and social progress is the work of single individuals. Such is the case

with regard to the treatment of habitual drunkards. We were indebted last year to Dr. Eastwood for a paper on Intemperance in its Medical and Social Aspects—one of the most interesting and suggestive papers brought before the Section; and I am happy to say we are this year promised another from the same pen, on Alcohol in Health and Disease. Dr. Eastwood and Dr. Elliot of Carlisle are doing much towards the practical solution of this social problem; but it is our excellent and valued friend Mr. Dalrymple who may be fairly said to have made this question his own. And with such energy and zeal has he taken it up, that I believe this most difficult and delicate question will in his hands be brought before long to a satisfactory settlement. I had hoped he would have been here, and himself have taken part in our discussions; but I understand he has gone to America, with the view of gathering materials for his own use in the next session of Parliament, in connexion with his Habitual Drunkards' Bill. How impressive the lesson conveyed to us of the strength and sadness of this master-passion, by the difficulty we experience in framing any measure whereby we may help its victims to struggle upwards from that deep into which the descent is so easy, but from which the return to light and freedom and a "right mind" is so rare. You may set almost any amount of machinery at work to deliver those who have become the slaves of intemperance, yet in the great majority of cases you will be checkmated in all your efforts. Still I believe that, in a certain proportion of cases of habitual intemperance, legislative interference—some provision for the enforced seclusion of those who are possessed with a madness for drink as well as from it—may prove effectual for their reformation. As, therefore, we are none of us blind to the great difficulties that surround legislation on this painful social problem, let us not withhold our countenance and counsel from those who are earnestly seeking its solution.

Another subject of great importance—the transmission of infection by means of fluids—was brought before us last year by Dr. Michael Taylor of Penrith, who, in an able paper to which I listened with deep interest, opened up to us a new chapter in sanitary science—a new and hitherto unsuspected source of infection. If any doubt lingered in the minds of any as to the entire conclusiveness of the proof then adduced, that scarlatina could be conveyed from a dairyman's house by the milk with which he supplied his customers, it was soon dispelled by the appearance of a masterly paper in which my old friend and colleague, Dr. Edward Ballard, traced an outbreak of typhoid fever in Islington during the months of July and August 1870, to the same cause—the use of impure milk, whereby a large number of persons were infected. These two monographs are of the highest possible importance, and will, I expect, now that public attention is directed to the subject, be followed up by many confirmatory contributions.

The distribution of disease throughout the kingdom is another subject of great moment, for the elucidation of which we are mainly indebted to one very zealous labourer, who has undertaken this truly national work—Mr. Alfred Haviland, an abstract of whose lectures at St. Thomas's Hospital has been presented to you in our JOURNAL. The first part of his great work has appeared since our last meeting, when Mr. Topley read a most interesting paper on the Distribution of Disease in the Northern Counties. And when, as I believe will be the case next year, Parliament shall have authorised a national registration of sickness as well as of deaths, we shall be put in possession of materials by the analysis of which Mr. Haviland, and others like him, will be enabled to render services a hundredfold greater than now to the common weal. We shall then be enabled not only to distinguish death from disease, but to map out the seasons when, and the districts where, diseases prevail extensively which are not followed by death, and of which as yet the Registrar-General's returns give no sign, though they so seriously disable large sections of the population from productive industry.

There is another subject in this year's programme which I may with great propriety place among those which owe their present development to the enlightened zeal of a few individuals—I mean sewage irrigation. There is no man in England who has done more for the solution of this difficult and long-voiced problem than my friend Mr. W. Hope, who is coming to tell us the results of his experience: first in the Lodge Farm near Barking, which he irrigated most successfully for several years with London sewage; and now in another farm, to which he is applying it, with the like result, that of Romford. This subject, considered in relation to the public health, is of vast importance; and I know of no one so thoroughly competent to deal with it as Mr. Hope, who, having won his spurs, and that decoration which every true soldier craves, on the bloody battlefield of the Crimea, is now reaping more lasting honours in the field of agriculture, and earning for himself the blessing which a grateful country will not fail to invoke on the man who makes, not two, but four or five blades of grass to grow where one grew before.

2. Let me now say a few words on the results of Associational effort. As regards medical reform, I more than ever heartily concur in the demand which this Association makes for the representation of the medical profession in the Medical Council. I feel that this Association—which I may say led the way on this question of medical reform, which fought the battle long ago, and was mainly instrumental, along with Mr. Headlam, in bringing about the settlement of 1858—has a right to speak, and will make itself heard, on this subject; and that in the next session of Parliament it will have power with the Government to give a right direction to any measure that may be brought in.

In the presence of Dr. Nankivell, who many years ago founded the Coventry Provident Dispensary, the great success of which has led to the formation of many others throughout the country, I scarcely feel warranted in speaking of these admirable institutions in connexion with Associational effort. But during the past year this question has entered, I venture to think, on a new phase, in consequence of a very able and comprehensive paper read by Mr. Fairlie Clarke last February, before the Metropolitan Counties Branch of this Association. Sir Charles Trevelyan, Mr. W. H. Smith, Mr. Corrance, Mr. Shaw Stewart, and Mr. Alsager Hill, were present and took part in the discussion, the direct result of which was the formation of a Medical Committee in connexion with the Society for Organising Charitable Relief in the Metropolis, to consider the regulations of existing provident dispensaries, and to draw up a code of rules, applicable both to town and country, for distribution throughout the kingdom. That task has been substantially accomplished, though the rules have not yet been issued. The interest which distinguished public men and members of the Legislature have of late manifested in this question, and the steps taken in reference to it by the Charity Organisation Society, show that the public mind is being at length directed to one important factor in our social economies—I mean the *free* dispensaries, with the mischievous tendency and results of which the medical profession have long been familiar. Many who have been thoughtlessly supporting these institutions are now beginning to see them in their true light, as exercising an unquestionably injurious influence in pauperising the working population.

As regards the preservation of infant life, some active members of our Association—Mr. Ernest Hart, Dr. Wiltshire, Mr. Curgenvin, and Mr. Benson Baker—have been earnestly engaged in promoting what is really the work of the Imperial Parliament, and should long ago have been taken up by Her Majesty's Government. For it should not be forgotten that it was the labours of members of our own profession, as recorded in the BRITISH MEDICAL JOURNAL—and not the investigations of the police, who ought to have been on the alert, but were not—that first compelled the attention, both of Parliament and of the police, to this most important question. I am happy to think that the Report of the Parliamentary Committee on this subject, lately issued, gives us at length the prospect of legislative interference; and it is to be hoped that in the next Session we shall see a stringent measure enacted for the prevention of that wholesale sacrifice of infant life, which has for so long been going on under the very eyes of the police, without any attempt on their part to check it.

3. As regards the proceedings of Parliament, I shall not enter upon the vexed question of the Contagious Diseases Acts. We had some very keen discussion upon it in the section of Public Medicine last year, but are not this year, so far as I know, threatened with a renewal of it. The subject has been pretty thoroughly ventilated, so far as Parliament and the country are concerned, by the labours of the Royal Commission, a copy of whose Report I have recently received. I see no reason to modify the opinion I last year expressed of the great danger of invoking the action of the Legislature to avert, even indirectly, the consequences of vicious actions committed by persons of sound mind, and of their own free will. That principle seems to me full of peril. Of the other aspects of the question I say nothing.

On another subject of the very first importance—I refer to sanitary organization and administration, to the right understanding of which our Association, in connection with the Social Science Association, has largely contributed,—the Report of the Joint Committee, for which we are indebted to my distinguished predecessor in this chair, Dr. Rumsey, is prepared, and will be considered at to-morrow's forenoon meeting. Let me now merely express the great regret we feel, in common with the members of the Royal Commission (vol. iii, p. 360), that the scope of the Government inquiry was so limited. We earnestly remonstrated against its being restricted to England and Wales, knowing that in Scotland and Ireland, as now stated by the Commission, "sanitary administration is in some respects in advance of us." We urged upon the Government the propriety of doing what the former Government considered right, and what, it now turns out, the Commissioners themselves wished, to be done,—though it does not appear that they said so, when such expression of opinion might have been useful,—namely, to extend the in-

quity, though not necessarily the subsequent legislation, to the whole kingdom and the metropolis, so that the whole facts should be before them and the country, ere entering upon a course of legislation, which, I apprehend, is intended sooner or later to embrace every part of the kingdom alike. However, that remonstrance was unheeded, and we are now seemingly about to legislate for the whole future local government of England and Wales, on a confessedly imperfect inquiry—declared with “much regret” to be such by the Commissioners themselves—and without full and trustworthy materials, derived from careful inquiry on the spot, for rightly determining the very grave and complicated questions involved in the settlement of the areas of administration. We feel also that we have a right to—and we do—complain that, while they were not only empowered by the terms of their appointment, but expected, to investigate with special care, and to report upon, the number of officers and the local expenditure, required under the present disjointed, chaotic, and fragmentary plan of operations, as compared with the coherent, orderly, and comprehensive system, suggested in our Memorial to the Government, the Commissioners have adopted the existing chaos as the *summum bonum*, have quietly ignored the existence of any other plan, and have furnished us with no data for determining the cost, either absolute or comparative, of that propounded by themselves. These and many other topics are discussed at length in the Report of the Joint Committee, and I trust that their labours will not be without effect in assisting Parliament during the next session to arrive at the solution of this great national problem. The proposal to constitute the Poor-law medical officers throughout England and Wales,—and ultimately, I suppose, throughout the United Kingdom,—officers of health, is most objectionable. A more fatal gift to the Poor-law officers, in their own interest as well as in that of the public, could not be made. We maintain, and we always have maintained, that there is an antagonism between the public service in these matters of preventive medicine, and the private interests of practitioners, which can only be solved by making each chief officer of health independent of private practice—by having a class of men who shall be free to do their duty as preventive officers without fear or favour. I believe that a large number of the Poor-law medical officers may be employed as deputies or assistants; but that they should bear the sole and individual responsibility, as well as *odium*, of the office which the Commission, with what appears to me cruel kindness, would provide for them, is what neither they nor the public desire or deserve. Upon this question, likewise, I hope that the whole force of both Associations will be directed upon the Government and Parliament during the next session; otherwise, we need expect nothing satisfactory in the way of sanitary organization. Mr. Davies of Bristol, and Mr. Dyke of Merthyr, have, at my request, prepared valuable papers on subjects having an important bearing on the execution of the laws relating to the public health.

4. But when, by dint of legislation, we have succeeded in making our sewers sweet; in preventing the evolution of noxious gases; in stamping out pestilence and every kind of infectious disorder; in making our sewage, which now blackens and pollutes our rivers, spread over our fields a mantle of luxuriant vegetation; in aiding our drunkards—some of them at least—to reform themselves; and in making our public women healthy, if not chaste and pure; have we done all that we can or ought to do, to make our sanitary and social state a wholesome one? A voice seems continually to be whispering in our ear the familiar saying, “You cannot make people virtuous by Act of Parliament”. And there does seem to me a real danger, while we keep our eye fixed on the external helps, of losing sight of the regeneration of the inner man—of forgetting that that which *alone* can make matters radically right is a moral change in the population. Let us not, while insisting on cleanliness, forget that godliness, according to the old saying, is its next of kin. There is no antagonism between them; they are, on the contrary, the closest friends. We have borne our part, as medical men, and as a profession, from the time of John Peter Frank until now, in the origination and working out of preventive medicine. From beginning to end it has been mainly the work of our profession; and if now at length much interest is beginning to be felt in these questions by outsiders, it is because the medical profession, getting little thanks for all their labours, had for more than half a century led the way. I well remember that somewhere about nineteen years ago the leading journal, not merely of this country but of Europe, said, “You cannot expect men who live by disease to exert themselves for the prevention of disease”. A statement more false in theory, more unkind in feeling, and more incorrect in fact, was never penned. Medical men live not by disease, but by the alleviation and cure of disease, against which they make war in every shape and form; and to the honour of medicine be it said, that in the present day they are living and working more and more for the prevention of disease. They are

making it more and more their business to hold out to the public the great and glorious boon, which the public is so slow to grasp, of many thousands of valuable lives rescued yearly from the great Destroyer, but a large proportion of which the public in its blindness as yet willingly lets die. I feel bound, therefore, to vindicate the claims of the medical profession to the public gratitude, and to testify my own appreciation of the value of their labours in preventive medicine.

But when all has been done that sanitary science can do, let us never forget that it is in the forces that act upon the mind and heart of man that the real secret of reformation dwells. And unless a “light from heaven” illumine the understanding and cleanse the heart, use what external means you may, you cannot put things thoroughly to rights. Those who have been much in the habit of working among the poor, as dispensary or Poor-law medical officers, well know that their dwellings are commonly a reflection of their minds and tastes. And until you can change these minds and tastes, you can have no satisfactory guarantee that what you do to-day will not be undone to-morrow. For, as our great poet has said,

“The mind is its own place, and in itself  
Can make a heaven of hell, a hell of heaven.”

But if we can combine the two great forces; if, by God’s blessing, we shall be instrumental in making the inward spiritual keep pace with the outward sanitary movement; then will ours be indeed a great moral mission, elevating while it purifies the masses of our population, making their hearts better, while it ennobles and refines their aims and aspirations; so that in the improved religious, moral, and bodily health of this great people, we may expect ere long to see exhibited, in its highest sense, that “mens sana in corpore sano”, which would fill the heart of every Christian philanthropist with joy.

## REPORTS AND ANALYSES

IN

### MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### ARNOLD AND SONS’ IMPROVED PORTABLE ENEMA.

MESSRS. ARNOLD AND SONS, of 35 and 36, West Smithfield, London, have brought out an excellent enema-syringe, which consists of an India-rubber bottle, fitted with a reversible pipe and mount, to which a cap is arranged, so that the enema can be carried about full of fluid

ready for use. The mounts are made of brass and carefully tinned on the inner side to prevent corrosion. The instrument is well fitted up

in various ways as a vaginal, urethral, rectal syringe, or otherwise, and will be found of great service, especially that for urethral injections, which may be thus carried about in the pocket ready for use at any time.

## BRITISH MEDICAL JOURNAL.

SATURDAY, AUGUST 26TH, 1871.

### THE BUSINESS AND CONSTITUTION OF THE ASSOCIATION.

WE have thought it right to maintain a considerable reserve in regard to the changes projected and in course in the organisation of our Association, and to avoid taking any part in the discussions thereon. In the presence of the proceedings actually taken at the annual meeting, it is perhaps desirable now to define in some measure their precise character and importance; and this course is especially called for by some of the accidental errors of statement and interpretation into which the passing chroniclers of the meeting have pardonably fallen, which would falsify the history of the Association if left uncorrected.

The proposed changes in the laws, proposed by the Committee of Council, have been advertised in our columns for several weeks, and in such a form as would make their meaning and object most clearly intelligible—in parallel columns by the side of the existing laws. When they were read to the meeting, it was at first proposed to take votes on them *seriatim*; and a commencement was made. The meeting, however, which had for weeks ample opportunity for considering them, was impatient of the delay; and an independent member of the Association rose and proposed, amid general expressions of assent that they should be considered as a whole—a proposition which was carried by acclamation. The President of Council, to whom the duty of proposing them was entrusted, yielded to the evident and loudly expressed wish of the meeting, and submitted them for consideration *en masse*. They were subjected to some purely verbal criticisms by Mr. Liddle, which met with difficulty on the point of order—that notice had not been given of the proposed changes of phraseology, as the laws require. But these criticisms, which were of a purely literary and friendly character, will of course be considered. Beyond these criticisms, the new laws passed unchallenged. The great point of novelty is, that they declare that the General Secretary, responsible for the business conduct and organisation of the Association, that he shall in the future do that for which he is responsible, and that, in order to do it, he shall reside near his work. There could be no doubt whatever in the minds of any who examined the facts of the case, of the urgent necessity of the change; and the only wonder was, that no one had before found the courage to propose what many had long felt to be necessary. Every one was aware that the Committee of Council met at Birmingham about four times annually, and during not more than a total of twenty-four to forty-eight hours in the year; that the annual meetings occupied three days; and that, during the rest of the year, the chief business of the Association—apart from its great autonomous Branches—no matter by whom transacted, was in London. It was then that the lists had to be kept and weekly method, in order

to keep members supplied with their JOURNALS; there, were the clerks of the Association; there, was its permanent chief expenditure; there, was collected the two thousand a year with which the JOURNAL advertisements now furnish the Association; there, also were transacted, of necessity, the business of the State Medicine Committee, of the Medical Reform Committee, of the Parliamentary Bills Committee, of the Poor-law Committee, the deputations to Ministers, and the communications with members and departments, which together constitute a large part of the vitality of the Association as an unit during the year, and form a large part of its claim to a character for usefulness and influence. That the executive officer of the Association should reside a hundred miles away from the daily and continuous business of the Association, in order that he might be saved a journey to be present at its quarterly Council meetings, was an anomaly which could not exist after it was openly stated and seriously considered. But the circumstances of origin, and mode of growth of the Association had to be considered; and so great was the reluctance to give to unquiet spirits the chance of raising from their tombs the phantoms of old provincial and metropolitan jealousies, that the reality of mismanagement was endured, rather than submit to the imputation of a desire to centralise. As a matter of fact, the fear has proved to have been as excessive as the pretence is flimsy. That the necessity of the change was so quickly and immediately realised, when stated, was no doubt in great measure due to the startling state of affairs disclosed by investigation, and described recently by the Honorary Secretary of the South-Eastern Branch, Mr. G. F. Hodgson, who has earned the thanks of the Association by his fearless energy and immovable public spirit in examining, and stating with irresistible logic and irrefutable accuracy, the facts of the case. The literal accuracy of that candid and clear statement being found to be beyond dispute, and considerably within the facts, the personal matter was already adjudged. Such things may be condoned. Under no circumstances could they be perpetuated. With a business man at the place of business, we may hope that the Association will no longer have to encounter the obstacles to prosperity and material progress with which in this respect it has had secretly to battle during late years. The change will bring no millennium; but, with a regular collection of subscriptions, a proper attention to its office-books, lists, and accounts, a fair service to its committees, and just courtesy and attention to its honorary officers and members, it will at least pursue unimpeded its natural growth.

The propositions of Dr. Steele and Dr. Wade were not passed; but in both cases this was rather owing to technical difficulties than to the absence of sympathy with the principles of the motions. It is clearly the opinion of the members at large that the elective element in the Committee of Council should be increased; and, seeing how much other elements of the Council have increased with the growth of Branches, it is logical that this should share the general development. The motion was wrecked on the second clause, which proposed to exclude Secretaries of Branches as *ex officio* members. But it should be remembered that this was based upon the evidence that a surprisingly small proportion of them attend. If their attendance were more regular, the objection would fall. Honorary Secretaries of Branches are so valuable as members of Council, that they must be retained at any cost; and it were to be de-

sired that all Branches should follow the example of a few, and pay the expenses of their Secretaries for attendance at the Committee of Council meetings. The first part of Dr. Wade's motion will no doubt be carried next year. Dr. Steele may profitably occupy himself, as he promises to do, with an endeavour to improve the mode of nomination. That which he proposed was technically impossible.

#### THE CHOLERA IN 1871.

It is extremely important at this moment to trace the course of the Asiatic cholera during the last year, and to define its line of march up to this time. It is full of instruction, and not without elements of promise. Dr. Fauvel, one of the most competent authorities, has analysed the official documents, and his conclusions are worth noting. It was in 1870 that the alarm was given at Constantinople of the outbreak of cholera at Taganrog on the Sea of Azof, and at Rostoff on the Don. Soon the principal cities of the Russian coast of the Black Sea were attacked in the course of the month of August—Kertch, Berdianska, Theodosia, Odessa, and even Poti, whence the disease propagated itself into the interior of the Caucasian provinces. As usual, the rapid propagation along the Russian coast coincided with the arrival, by steamship, of travellers starting from the infected points. There was no mistaking that it was an epidemic of Asiatic cholera coming from the interior of Russia, with the movement produced by the transport of grain to the point of embarkation. This epidemic was otherwise remarkable for the slowness of its intensity—that is, for the small number of attacks. At the end of September it was everywhere on the decline, and subsequently died out along the coast.

An important fact to be observed in regard to this epidemic is that, thanks to the measures of quarantine enforced by the Ottoman sanitary authorities, the Turkish coast was completely saved from the disease in spite of the numerous arrivals from the infected ports. Thus, from the 2nd August to the 21st September, not fewer than seven hundred ships, amongst which were several having cholera on board, were submitted to quarantine at the mouth of the Bosphorus.

Whence did this epidemic come? The first idea which occurs is, that this was simply an extension of the malady which reigned at the commencement of the year in the provinces of Central Russia, and was propagated to the South with the commercial movement above mentioned. At Constantinople another opinion is entertained. They have the conviction, based on documents whose value is not yet ascertained by continental authorities, that this epidemic, and even that of the close of 1869, was due to Persian importation. The disease is declared to have broken out at Nijni Novgorod at the time of the fair, and with the arrival of the Persian merchants.

This question is one which, as Dr. Fauvel points out, is of great European importance. If, as the prevalent opinion runs, the actual epidemic be only a sequence of the importation of 1865, a recrudescence such as is often observed in imperfectly extinguished foci of disease, this epidemic is distinguished from those which precede it in its course of invasion, and would tend to prove that cholera has found in Russia conditions favourable to its genesis and acclimatisation. If, on the other hand, the existing epidemic have for its origin a Persian importation, it falls then under the ordinary rule of epidemics of cholera due to a reimportation of the disease. This is a question which it behoves the sanitary administrators to solve.

We give elsewhere the figures of the cholera cases during the present year at St. Petersburg. They have not caused there, nor do they even now cause, much anxiety in the city itself. They are not very numerous and not very fatal. St. Petersburg is but too well accustomed to the presence of cholera. Of all the great cities of Europe, it is the one in which cholera, once imported, maintains itself with the greatest tenacity. But the disease has spread into more menacing quarters—to Moscow, and thence to Tambov. Spreading through the West, it has passed into Russian Poland, notably to Wilna, and is now crossing the Prussian fron-

tier to Königsberg. On the other side it has appeared at Riga, and thus threatens us through our maritime relations. We are on our guard in this direction, and cannot be too earnest and watchful. It is clearly the Asiatic cholera which is invading us; but possibly it is only the tail of the old Russian epidemic of 1865, in a feeble and benign form.

DR. W. H. CORFIELD, Professor of Hygiene in University College, is a candidate for the post of medical officer of health for Islington.

IN the week ending August 12th, only one death, that of an infant under twelve months of age, was registered in the parish of Clifton (Bristol), showing a rate of mortality of 1.9 per thousand per annum.

THE Directors of the British Home for Incurables acknowledge, with grateful thanks, a third donation of £1000 to the funds of the charity from C. D. T.

A FALSE report has been spread of the death of Garibaldi; he appears to have been seriously ill, but to have recovered. He is martyred by a severe form of chronic rheumatism.

THE Governors of St. George's Hospital have just received a second munificent donation of £1000 from an anonymous donor under the initials of "E. G. N."

THE mortality in Paris during the week ending the 18th inst. was 828 against 676 in the previous week. There were 31 deaths from cholera, 55 from diarrhoea, and 1 from cholera.

#### THE CITY OF SUICIDES.

THIS title no longer belongs to this metropolis, if it ever deserved the sad appellation. The ratio of suicides has been established by M. Decaisne recently, before the French Academy of Sciences. It is in London only one in 175 deaths; in New York, one in 172; in Vienna, one in 160; but in Paris, it has reached one in 72. The number of suicides from drunkenness which in 1848 was 141 for all France, reached 401 in 1866.

#### SIR RICHARD WALLACE.

EVERY one who knows how nobly Mr. Richard Wallace devoted his time and money to the relief of the sick and wounded in Paris during the two sieges, will be pleased to hear that Her Majesty has recognised his services and granted to him the dignity of a baronet.

#### CONDURANGO.

THE new alleged remedy for cancer appears to be creating no little excitement in America. A correspondent writes to us stating that it is scarcely to be procured, so great is the demand for the plant. Thousands of dollars are being offered and given for small quantities. He adds that it has been tried in the Government Hospital at Washington, but not with encouraging results. The plant is being in the meantime used in the cancer wards of the Middlesex Hospital.

#### DISINFECTANTS AND SANITATION.

THE present urgency of sanitary precautions has turned attention to the subject of disinfectants once more. In some interesting observations of M. Dumas, the celebrated French chemist, at the Academy of Sciences, the question is succinctly treated. All chemists agree that the chloride of lime decomposes the foul hydrogen gases diffused in the atmosphere. As to carbolic acid, its action is twofold. It averts the decomposition of organic albuminoid matters, and further possesses the powers of killing the germs, the organic agents, whose development engenders or propagates epidemic diseases. Hence, M. Dumas considers it necessary to reserve chlorinated fumigations for disinfecting the air, but to employ also carbolic acid, the vapours of which in some sort seek out and destroy in a vitiated atmosphere, its miasms and morbid germs. Disinfection and sanitation is a twofold operation; it is desirable to utilise simultaneously chlorine and carbolic acid.

## MRS. GLADSTONE'S CONVALESCENT HOME.

It appears from Mrs. Gladstone's appeal in the *Times* for funds to carry on the present work of this Home, that the benefits of the charity have become much extended. The Home has accommodation for between seventy and eighty patients of both sexes, whereas it was originally intended for men only.

## SOCIAL SCIENCE ASSOCIATION.

THE annual meeting of the Social Science Association will be held at Leeds from the 4th to the 11th October, under the presidency of the Right Hon. Sir John Pakington, Bart., M.P. In the Department of Health, the officers will be—*President*, George Godwin, F.R.S.; *Vice-Presidents*, Charles Chadwick, M.D., D.C.L.; Edward Filliter, C.E.; J. D. Heaton, M.D.; Frederick J. Mouat, M.D.; F. S. Powell. The following questions will be discussed in the section: 1. What are the best and most Economical Methods of Removing and Utilising the Sewage of large Towns? 2. What are the best Means of Securing the Sanitary Improvement of Human Habitations? 3. What are the best Means of Promoting the Health of Operatives in Factories and Workshops?

## HOSPITAL ACCOMMODATION.

THE Medical Department of the Privy Council has just issued a memorandum on the hospital accommodation to be provided by sanitary authorities for the purpose of separating the sick from the healthy in outbreaks of infectious disease. The memorandum rightly insists on the importance of having such accommodation provided beforehand. As to villages, it is recommended that each should have the means of immediately accommodating four cases of disease in at least two rooms without requiring removal to a distance. When circumstances demand, further temporary provision must be made. In towns, more accommodation will be required, in proportion to the size of the town; and there should be a permanent building, with space enough around it for the erection of temporary structures if necessary. These latter may consist of huts in winter, or of tents in summer and autumn; and directions as to the construction, ventilating, and cleansing of them are given. The memorandum is likely to be of service; for, though the Sanitary Act of 1866 makes it a duty of parochial authorities in many localities to provide hospital accommodation, there has been no authoritative document to which reference could be made for guidance.

## THE PLYMOUTH GUARDIANS AND THEIR MEDICAL OFFICERS.

CIRCUMSTANCES have lately occurred in connection with the administration of Poor-law medical relief in Plymouth, which at one time wore a threatening aspect, but which happily now give promise of being brought to a satisfactory termination. A short time ago, the guardians determined on reducing the number of district medical officers in the town from four to three, making a new arrangement of the districts. Two of the then existing medical officers—Messrs. Harper and May—thereon resigned their posts; and none of the medical men in Plymouth offered themselves as candidates. The guardians then advertised for medical officers; and nine or ten gentlemen residing in various parts of the kingdom offered themselves. Of these, Mr. Henry Lupton, a gentleman residing in Chelsea, was successful; but, on learning the circumstances in which the election had taken place, he very honourably declined the appointment, stating that he "was of opinion that it would not be acting rightly towards the two gentlemen who had lost their appointments, for him to accept the appointment in question". This withdrawal of Mr. Lupton caused the matter to be again freely discussed at a meeting of the Board on the 16th instant. In the discussion, some of the members who had on the former occasions advocated the reduction, now acknowledged that they had been in error; and ultimately a resolution was carried by a majority of 11 to 6, to refer the whole matter to a committee to report on at the next meeting. There seems to be no doubt that good sense will prevail, and that the old number of four medical officers will be retained. We may reasonably believe that the discussion on Poor-law Medical Relief in the Public Health Sec-

tion of the annual meeting, which took place a few days previously, had a beneficial effect on the minds of the guardians: in any case, it was one by which they could scarcely fail to be enlightened. It is only just, in conclusion, to refer with high approbation to the *esprit de corps* manifested on this occasion by the profession in Plymouth, and to the honourable conduct of Mr. Lupton—examples which we should be glad to see followed in other places.

## THE EXAMINATION OF WATER FOR SANITARY PURPOSES.

DR. BISCHOF read a paper at the British Association at Edinburgh on the Examination of Water for Sanitary Purposes. The object was to show that the examination of the residue enables chemists to judge in a measure of the quality of the water. If the water be pure, the crystals are clean; if it be impregnated with organic matters, the crystals are more or less discoloured. Dr. Voelcker suggested that it would be interesting to know how far the crystal forms were modified by different kinds of organic matter. There were organic matters of vegetable origin such as they found in great abundance in St. Mary's Loch, and there was animal matter, and it would be useful if they could tell from the residue which kind of origin the matter had.

## THE "ECHO" AND THE HAMPSTEAD SMALL-POX HOSPITAL.

WE think that the Hampstead Small-Pox Hospital authorities have good cause to complain of the imputations made against them by the *Echo*, that a child treated at that hospital for small-pox had been so neglected that it had lost its entire sight; and not less open to criticism are the remarks which were made by Sir Thomas Henry on their appearing to prosecute the proprietor and publisher of the paper. It was not denied that the child had been treated in the hospital, and had partially lost its sight, but this is a frequent and natural consequence of small-pox, and evidence was not forthcoming to prove that the injury to the eyesight was due to neglect. Sir Thomas Henry, indeed, admitted that "no doubt the ladies of the charity and the surgeons were doing all they could," but yet ventured to say that "it was a matter of opinion whether the child had lost its sight from neglect or not, and that the public press were at liberty to comment on the case in this wise." Surely this is peculiar reasoning. It simply amounts to this, that papers may publicly slander hospital authorities as much as they please without the least foundation for their statements, and without the libelled persons obtaining any redress should the statements be false.

## WHAT DOES IT MEAN?

A PERSON interested in the female medical movement writes to us as follows:—Of what shall the lady medical students henceforth have to complain? If they have not received their due in Edinburgh, a prophet has arisen in the metropolis of the United Kingdom who promises such a feast as shall afford a princely entertainment not only to the redoubtable seven Amazons in the North, but to legions of female aspirants to Æsculapian art. Some unknown benefactor of the sex has prepared for their reception "The British Medical College for Women", the spacious class-rooms of which appear to be enclosed within the walls of a "Hospital for Diseases of the Heart, No. 85, Newman Street, Oxford Street". Even "the waiting-room, consulting-room, house-surgeon's-room, and dissecting-room", forsooth, besides other apartments, are to be placed in the most generous manner by the Committee of the Hospital in the hands of this great and unknown benefactor. But the programme does not end here: a charter is to be obtained and a staff of examiners is to be appointed—not only so, but a Council, and so forth. The matriculation examinations are to be of a stringent character, and due precautions are to be taken that "every member of the College shall limit her practice to the treatment of women and children"; in the case of boys, however, modesty forbidding that they should have seen more than five summers. And again, "members of the College shall not enter into conversation with their patients on subjects of religious controversy, politics, or family matters". Is the circular before me a joke? Emanating from a "Hospital for Diseases of the Heart", and clothed in

such an air of mystery, it looks uncommonly like it. If so, it is a cruel piece of wit.

#### ST. PANCRAS AGAIN.

THE notorious St. Pancras Guardians have again been several times, during the past ten days, the subject of public scandal. The Board of Guardians last week thought fit to throw dirt at one another and expose themselves to public scorn over an anonymous letter reflecting, in the most serious manner, on the character of Dr. Ellis, the Resident Medical Officer, and the Matron. This letter had been the subject of investigation by a Committee, who had reported that they were unable to find any truth in the statements made. Although some of the guardians during the meeting kindly consented to admit that others of their number, the Chairman included, were "hail fellows, well met," the Chairman repudiated with indignation his possessing any of the social qualities imputed to him. The Poor-law Board had taken cognisance of the reports which had reached them regarding the Resident Medical Officer, and had addressed a letter to the Guardians on the question. The matter, after a very exciting meeting, during which one of the Guardians appears to have allowed himself to be carried away by the strains of a well-known comic song, was referred back to a Committee. Again, on Thursday, Dr. Lankester held inquests on the bodies of two persons who had died in the St. Pancras Workhouse, which brought to light imperfections (at which one can scarcely be surprised) in the nursing arrangements of the workhouse.

#### SCOTLAND.

##### CRAIG VERSUS JEX BLAKE.

WE understand that nearly eight hundred pounds have already been subscribed to defray the expenses, amounting to nine hundred pounds, which this trial laid upon Miss Jex Blake.

##### PRECAUTIONS AGAINST CHOLERA.

CONTINUED precautions are being taken at the Scotch ports to prevent the introduction of cholera. This is rendered necessary from the large number of Scotch vessels trading with the Baltic. At Granton, the coast-guard tender *Squirrel* has been placed under the direction of the Collector of Customs, and all vessels about to enter will be examined. Several fatal cases of cholera had occurred on board a Dundee vessel on her way from Königsberg, but the bodies were buried in Germany. On arriving at Dundee, the vessel was overhauled by the authorities, and all necessary precautions taken to disinfect the ship. The crew was in good health.

##### [ ST. KILDA.

THE sad sanitary condition of the island of St. Kilda, one of the Hebrides, which has been brought into prominent notice by Professor Corfield in the *Times*, will, it is hoped, receive official attention. According to the census which has just been supplied—the island having been, strangely enough, altogether forgotten during the late census-taking—the population is 71, 43 females and 28 males. There is only one child, and it is dying. For the last eight years, the children born on, or brought early to, the island have not survived; and there is a decrease in the population since the last census. In looking for the causes of this great and constant mortality, it is stated that the air of the island is good, and the water excellent, but that "the huts of the natives are small, low-roofed, and without windows, and are used during winter as stores for the collection of manure, which is carefully laid out upon the floor and trodden under foot till it accumulates to the depth of several feet." It may well be asked who is the proprietor of the island.

GENERAL INFIRMARY, NORTHAMPTON.—£2,400 has already been subscribed, out of £3,500, the estimated expense of erecting rooms for out-patients and furnishing the new wards.

#### THE VACCINATION BILL.

OUR Association is greatly indebted to Lord Redesdale and those who voted with him in the House of Lords, for giving effect to the remonstrance against the tenth clause of the Vaccination Amendment Bill, which made immunity from vaccination purchasable by a fine of twenty shillings. This was a concession on the part of the Government to the outcries of the anti-vaccinators, which had the peculiar disadvantage of operating unequally on the rich and the poor, and of introducing a dangerous element into sanitary legislation. It was obviously well intended, and in some respects perhaps prudent. But the objections to it had determined our Parliamentary Bills Committee specially to protest against it in both houses; they were outvoted by the Government and Mr. Chambers in the House of Commons; they are indebted to Lord Redesdale for a victory in the House of Lords, which will benefit the health and satisfy the conscience of the public.

#### THE CHOLERA.

CHOLERA is steadily marching onwards, it having spread along the banks both of the Tigris and Euphrates. Cases have occurred at Kerbela on the latter river; and even in Bagdad one case is reported. As regards the former river, cases are reported as having occurred as high up as Mendeli.

DURING the week from July 19th to 25th, 197 new cases of cholera occurred at St. Petersburg; the number of recoveries was 185, and of deaths 117. From the commencement of the epidemic, the numbers have been: cases 6,971; recoveries 3,692; deaths 2,876. In Cronstadt, from June 24th to August 5th, there were 444 new cases, 198 recoveries, and 218 deaths.

##### CHOLERA PREPARATIONS IN SWEDEN.

WE believe that active steps have been taken by the authorities in Sweden to deal with any cases of cholera which may happen to be brought within their jurisdiction, and that these steps include the provision of hospital accommodation to a considerable extent.

##### PRECAUTIONS AGAINST CHOLERA IN THE PORT OF LONDON.

DR. BUCHANAN, the Medical Inspector of the Privy Council, who has been charged with the supervision of the precautions against the importation of cholera into the Thames, has held communication with the Board of Customs, the Trinity House, and the Thames Conservancy, as also with the authorities at Gravesend, and with the health-authorities of all the riverside districts below London Bridge, in order to obtain their harmonious co-operation in carrying out a complete and uniform system. The necessary work will mainly be done at Gravesend, where ships are boarded by the Custom House officers, and where the presence of cholera among the crew would be detected. It would, however, be manifestly unfair to make the expense of removing and providing for such patients, and of supervising disinfecting processes, a local charge upon Gravesend; and one of Dr. Buchanan's main objects has been to bring about a consent that the cost of measures for the protection of all the river-side districts should be equitably divided among them in proportion to the rateable value of each, although the Customs boarding station fixes the place at which the duty must chiefly be discharged. Pending the result of the efforts thus made to insure combined action, Dr. Buchanan has held communication with all the medical officers of health, and with other health-authorities in certain districts, in order to secure that they may be prepared for the duties which may devolve upon them, and fully acquainted with the steps which they will be called upon to take if cholera should appear. The Medical Department of the Privy Council has, therefore, done, in the way of instruction, advice, and warning, everything that the powers committed to it will allow, and the responsibility of acting rightly will devolve upon local officials. The *Times* understands that Dr. Buchanan has everywhere been met in an excellent spirit, but that unavoidable delays have been produced by the absence of some of the persons whose assistance is required. In the meanwhile, Gravesend has been fighting her own

battle, and, although quite ready to enter into the proposed combination, and to bear her proper share of the expense, has sent a deputation to Mr. Stansfeld to protest against being saddled with the whole cost of guarding the river and the metropolis. Mr. Netten Radcliffe has gone to visit the ports from Boston to Southampton, and, whether cholera be brought to our shores or not, the alarm is at least doing good service in many directions. The combined action of neighbouring local authorities has never before been obtained for any sanitary purpose, and it cannot fail to form a precedent which is not likely to be forgotten or neglected in future emergencies.

#### THE CHOLERA IN GERMANY.

ADVICES from Gumbinnen dated August 19th, state that cholera has made its appearance in districts on this, the German side of the frontier, namely at Pillkallen, Oletzko, Lyck, and Moberburg.

Advices dated August 22nd state that cholera still prevails at Konisberg. On the 18th and 19th inst., 111 cases occurred, of which 56 proved fatal; on the 20th, 87 persons were attacked, and 32 died. At Dantzic and Elbing, a few cases occurred. No case has occurred at Stettin.

Asiatic cholera has been confined in the north to the district of Suwalki.

According to the *North German Gazette* of Wednesday evening, four cases of cholera have occurred in Berlin, two of them proving fatal.

#### FAMINE AND CHOLERA IN PERSIA.

A TELEGRAM received on August 5th by the Galata Board of Health from Tabreez reports the rapid spread of cholera in that city. In the previous week, the deaths from the epidemic averaged two hundred a day; and when the telegram was despatched, the inhabitants were flying in thousands to the villages towards Oorumiah and Khoi. The intelligence also at Tabreez at the same date was that the famine in the southern provinces, instead of abating, was "worse than ever."

#### THE CHOLERA IN RUSSIA.

THE sum of the epidemic of cholera in Russia, from its appearance on the 17th (29th) August, 1870, to the 19th (31st) July, 1871, gathered from Russian official documents, is as follows:—Cases: 4,568 men, 2,249 women; total, 6,817. Cures: 2,346 men, 1,196 women; total, 3,542. Deaths: 1,938 men, 859 women; total, 2,797. Thus, although the epidemic has been persistent, it has not been very fatal; its mean daily mortality during the year not exceeding 9. It must be admitted, however, that at some points recently it has shown considerable intensity, especially at Tamboff and Joroslav. But in both it is becoming feebler at this moment. There is considerable reason to believe that the present outbreak is to be regarded as a recrudescence of the epidemic of 1865, not yet extinguished in that country.

Advices from the Russian province of Suwalki state that cholera is on the decrease. From the 20th to the 27th July, there were 238 fresh cases. The whole number of cases that had occurred was 443, and of the persons attacked 83 had died, while 190 had recovered.

## CORRESPONDENCE.

#### THE ADDRESS IN MEDICINE.

SIR,—In the Address in Medicine at Plymouth, Dr. Johnson thought proper to refer to a lately published clinical lecture of mine on Functional Medicine. He had seen therein a passage in which I had stated that disease (though often vulgarly so considered) was in but a few cases an actual entity existing within the body, and I referred as an example to one single instance.

From those premises he thought proper to infer that I denied the introduction into the system of any actual poison in such diseases as the exanthemata. Now, in the first place, as I admitted that in some few cases (besides the one cited) there was such an entity, it is obviously not logically justifiable to assume that in my opinion the exanthemata were not amongst them.

In the next place, Dr. Johnson can scarcely be ignorant that I was the first to advocate the eliminative treatment of diphtheria, on the very ground that the source of it was a putridy poisoning of the system, and not, as had been previously taught, a secondary poisoning. Nor have I given him any ground for stating that I have altered my views on this subject.

And lastly, in the very lecture referred to, and which I presume Dr. Johnson has read through, I refer at some length to syphilis as another

instance of a poison introduced into and existing in the system, which may be more or less effectually cast out.

It is equally difficult for me to conceive that Dr. Johnson could have made such a mistake, through inadvertence, as it is to suppose that he did it knowingly and wantonly.

I am, etc.,  
Birmingham, August 1871.

WILLOUGHBY F. WADE.

SIR,—The Address in Medicine lately delivered at Plymouth again revives the question as to the "stopcock" action of the small arteries in cases of blood-poisoning; and, whilst asking a portion of your much coveted space, I will engage not to travel over old ground, but simply to contrast cases of blood-poisoning from disease, with those in which action is the result of experiment, and, in short, to compare theory with hypothesis.

In the Hastings Prize Essay, Dr. Fothergill teaches us that, in cases of poisoning by digitalis, the heart and arteries alike contract to an extent proportioned to the dose given, and we know that this teaching follows upon actual experiment; moreover, we use digitalis daily, and not simply because it is a diuretic.

The theory of the stopcock action of small arteries is, that their contraction is spasmodic, and with a view to shut off poisoned blood, whilst the heart, on its part, and for life itself, hypertrophies in its endeavours to fight against them. We are thus taught, on the one hand, that a vegetable poison acts uniformly upon the circulation, and, on the other, that the poison of disease has an influence restricted to the small arteries—that is, to a very uncertain area, and are as yet undefined.

Can this be so? Has experiment ever determined the latter as clearly as it has the former? I am, etc.,  
FRED. SIMMS.

Wimpole Street, August 1871.

#### THE ANNUAL MEETING PHOTOGRAPHED.

SIR,—The late meeting of the British Medical Association at Plymouth was undoubtedly a great success. It was as pleasant as brilliant weather, genial hospitality, and a hearty welcome from all classes, could make it. There were, perhaps, one or two breezes just at starting; and the attention given to Sections was scarcely what was due to many laboriously prepared papers. Holiday-making was in the ascendant; but these things, no doubt, can be amended at future meetings. I have, however, one suggestion of a practical character to make, which I think will add to the pleasure as well as the profit of these annual gatherings. We all know how it is when we come to be mixed up with a crowd of gentlemen from all parts of the kingdom, many of whom we would gladly know—at least by sight—and many others whose acquaintance we would gladly make, commissioned perhaps by messages from mutual friends. My suggestion is as follows.

That each gentleman who comes to the annual general meeting should bring, or better still, send, his *carte de visite*.

That each Branch should provide its frame, or frames, for the reception of the *cartes* of its own members.

That to each *carte* should be appended the signature, or (as medical signatures are not always very legible), the calling-card, of the member.

That these frames should be suspended in some suitable position, either in the Museum or reception-room, easily accessible to all.

That to each frame should be fixed a small piece of ribbon, of the colour chosen by the Branch. That each member should also wear, attached to his button-hole, a small piece of ribbon, of the colour selected by the Branch to which he belongs.

At the close of the meeting the *cartes*, but not the frames, should remain the property of the Branch at whose centre the annual general meeting is held.

It is perhaps superfluous to point out the advantages I anticipate from my proposal, as I think they speak for themselves; but I think all will agree that the collections thus annually accumulated at the various Branch centres will become interesting and valuable mementoes in future years.

I have named this proposal to one or two of the gentlemen who were at the Plymouth meeting, and I am happy to say it met with their full approval. I am, etc.,  
SPENCER THOMSON, M.D.

Ashton, Torquay, August 21st, 1871.

DEATH FROM THE STING OF A WASP.—An old man, named Henry Moot, belonging to Cefelangen, was stung by a wasp on the finger one day last week; but, although it caused him a little pain at the time, he neglected to pay any attention to the wound. Two days afterwards, however, his hand, and ultimately his arm, became inflamed and greatly swollen, and, although every attention was paid to him, he died after a few hours of intense suffering.—*Swiss Times*.

# THIRTY-NINTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

Held in *PLYMOUTH*, August 8th, 9th, 10th, and 11th, 1871.

## PROCEEDINGS OF SECTIONS.

**SUBJOINED** are abstracts of most of the papers presented to the several Sections of the Association at the Annual Meeting, with some notes of the discussions which took place. The papers themselves will, as opportunities occur, be published in full in the *JOURNAL*.

### SECTION A.—MEDICINE.

*President's Address.* By C. BARHAM, M.D.—The President, after alluding to the absence of Dr. Acland, whose disconnection with the Association had resulted in his occupying that position, said he thought the most interesting form an address could assume would be an inquiry into some topic of medical interest peculiarly local. He had selected that of the health of Cornish miners, which he should treat in connection with that of the miners of Durham, Northumberland, and Staffordshire. The two royal commissions that had been issued had resulted in several reports and a volume of statistics on the subject. He should not enter into these, but should examine into the comparative longevity of the miners in the different counties. The most conspicuous form of disease prevalent among miners could be traced to the ill-effects of mining on youth, and resulting in the terrible sacrifice of life, and was consumption. The deaths from ordinary causes between the ages of 35 and 40 among the miners of Cornwall were not more than those of Northumberland, Durham, or Staffordshire; but the deaths from consumption in Cornwall were immensely in excess of the other districts. The rate of deaths from heart-diseases in Cornwall did not equal that of Northumberland; while for accidents no other district was at all to be compared with Staffordshire, where seven out of 10,000 died by those violent explosions that create such alarm every now and then. With regard to the causes of consumption in miners, it was to be attributed to the want of light and air, to exposure, and to liability to inflammatory affections, the result of too early employment. Some of the mining children worked as early as 13. Referring to the climate of the Scilly Islands, Dr. Barham observed that it was the best that could be found in England, and recommended it for invalids.

*Experiences of Cholera in India and its Treatment.* By Inspector-General JOHN MURRAY, M.D.

*The Pathology and Treatment of Cholera.* By GEORGE JOHNSON, M.D. [These papers have been published in the *JOURNAL* of August 12th and 19th.]

Dr. J. A. BOLTON stated that some years ago in a town where there were 1700 cases of cholera, the medical men, finding the water-supply impure, stopped up all the pumps, and sent for water from a distance. They gave the patients good animal food and clear cold water; after which the disease lessened, and many patients who were in a state of collapse recovered.—Dr. DAVEY said that seventeen years ago he had in the *Lancet* recommended calomel and colocynth in the treatment of diarrhoea and cholera.—Dr. MURRAY said that Dr. Johnson appeared to confound elimination with purgation. The elimination by the natural functions without violent symptoms was Nature's cure, as shown by the course when the disease was confined to the stage of malaise. We should endeavour to assist Nature, by restraining the further advance of the disease, of which the most dangerous symptom is looseness, whether naturally induced by indigestion, by improper food, or by purgative medicines. The case of fatal collapse following the cessation of the evacuations after the use of opiates might be very correctly reported; but that was not the ordinary result of checking early diarrhoea. Of the 505 medical officers in India, whose opinion Dr. Murray collected in 1864, there were only eight who did not consider the administration of purgatives in the early stage as dangerous. In the reports received from America, similar views of the danger of purgatives—even castor-oil—were entertained. He had seen cases where the rice-water evacuations in collapse were instantly arrested by the use of a saline enema; and where reaction gradually came on, and where the bowels were not again opened for twelve hours, and in one case two days, and perfect recovery followed. He urged that all persons who wished to avoid cholera should eat only of digestible food.—Dr. JOHNSON said the main difference between Dr. Murray and himself was with regard to the treatment of the early stage of cholera. Dr. Murray considered evacuations dangerous, and opiates safe; while he (Dr. Johnson) held an opposite opinion with regard to both classes of remedies.

*The Treatment of Hyperpyrexia, as illustrated in Acute Rheumatism, by means of Cold Applications Externally.* By WILSON FOX, M.D.—The author related two cases, in which entire recovery, under the use of the cold bath, ensued, after the temperature in one had attained the height of 110 deg., in the latter of 107.3 deg. In the former case there was deep coma; in the latter delirium. The nervous symptoms disappeared in both after the first reduction of temperature. In the first case moderate pericarditis was present; in the latter a very large pericardial effusion, and also a double pleuropneumonia, prior to the rise of temperature and the employment of the cold applications. In the first case the pyrexia, prior to the sudden increase of its intensity, had been very moderate, the temperature not exceeding 102 deg.; but on the fourteenth day of illness the temperature rose within nine hours from 102 to 106.4 deg. Two drachms of quinine, given within four hours in divided doses of a scruple, failed to check the rise of temperature, which within twelve hours had amounted to eight degrees. Ice-water poured over the body, and ice applied to the chest, abdomen, and spine, reduced the temperature in the rectum within half-an-hour to 103.6 deg., and a subsequent further fall took place during the succeeding hour, when the patient was in bed wrapped in blankets, to 97.4 deg.—there having thus ensued a total reduction of the temperature in the rectum of 12.4 deg. within an hour and a half, the patient having been only exposed to the cold during half-an-hour. A gradual rise of temperature of 7.6 deg., occupying twelve hours, then ensued, the temperature reaching 105 deg. A bath of twenty minutes' duration (temperature 64 deg.) reduced the temperature in the rectum 1.1 deg.; but the fall continued after the removal from the bath for another hour, with a total reduction of the temperature in the rectum within this time by 5.6 deg. A tendency to a rise of temperature persisted during two days longer; but was kept, by means of an ice-bag more or less continuously applied to the spine, below 103 deg. The treatment by cold was in this case maintained during four days. The fever lasted to the seventh day after the commencement of the treatment, which, however, was not maintained during the last three days. In the latter period the patient had a return of perspiration and of the pains in the joints. She had some bronchitis in the first days of the treatment by cold, which greatly improved while this was persisted in. The pericardial effusion diminished while the cold was being applied, and subsequently entirely disappeared. The patient was discharged thirty days after the intense pyrexia, and forty-four days after the commencement of the disease.—In the second case, the temperature before the hyperpyrexial attack had been higher, sometimes reaching 104 deg. The patient had extensive pericardial effusion and a double pleuropneumonia prior to the attack and before the application of the cold. Delirium set in, with a rise of temperature to 107.3 deg., on the seventeenth day of the disease and the sixth day in hospital. Half a drachm of quinine, given in a single dose, failed to check the rise of temperature. A bath of twenty minutes' duration, at a temperature of 86 deg., reduced the temperature in the rectum by 4.2 deg. A further fall followed removal from the bath, until the total reduction within an hour amounted 9.5 deg. The pyrexia in this case was, however, more obstinate than in the last. Cold applications, consisting of baths, ice to the spine, and packing in wet sheets wrung out of iced water and changed every half-hour or twenty minutes, were continued during seven days. The fever lasted in a continuous form until the twenty-fifth day after the extreme pyrexia and the forty-third of the disease, when it became normal; but occasional exacerbations occurred until the sixty-first day of the disease. The double pleuropneumonia resolved during the seven days, while the patient was being treated by the cold applications. The pericardial effusion, which at one time had reached the clavicle, greatly diminished, and subsequently disappeared, though some enlargement of the heart remained. While the fever was still present, sweating and pain in the joints returned with some severity.—In commenting on these cases, the author remarked that recovery in acute rheumatism rarely if ever took place after the temperature had risen above 106 deg., and that in all the recorded cases death occurred within a few hours after 107 deg. had been attained. No other treatment had been shown to be capable of averting the rapid rise of temperature which had taken place in different cases after bleeding, and the administration of digitalis, veratrum, opium, calomel and opium, and large doses of quinine. He considered, therefore, that the present plan was the only one which, as far as was yet known, could be pursued with success. Of the methods employed for the reduction of temperature, total immersion in a bath of from 60 to 80 deg. was the most efficacious; but it required caution, as the fall of temperature persisted long after the patient's removal from it. The wet pack, frequently changed, stood next in order of utility; the ice-bag to the spine had least power, but might be used when the rise of temperature was slow. The author considered that the period when the treatment should be commenced was when the temperature

exceeded 106 deg. This treatment was not to be considered as a cure for acute rheumatism, but only as a means for averting a dangerous complication. The rheumatic joint-affection returned in both these cases after the pyrexia had subsided. He believed, however, that no complications should interfere with its employment under the circumstances indicated; and in both these cases not only were no complications to be attributed to the treatment, but severe visceral inflammation subsided while it was continued. Brandy was given largely in both these cases; but the author did not consider that this would be necessary in all, but each case must be treated according to its individual indications. The author thought that other medicinal interference, unless specially indicated, had better be discontinued during the employment of the cold. It was probable that this treatment would be applicable to the same phenomenon occurring in the whole class of acute febrile disorders, in nearly all of which it might be an occasional complication, as in typhoid and typhus fevers, scarlatina, tubercular meningitis, pyæmia, and in sunstroke—in which latter disease the cold affusion had already been employed with advantage.

*On the different Therapeutic Indications of Rheumatism and Neuralgia, and some Remarks on Rheumatism as a Sequela of Diphtheria.* By D. DE BERDT HOVELL, F.R.C.S.E.—Rheumatism and neuralgia were stated by Mr. Hovell to be conditions of ill-health attendant on depression or loss of nerve-power, and both highly susceptible of pain. The first object of treatment in rheumatism was to eliminate the poison of lactic acid and other allied acids from the blood, and reduce the excess of fibrine by the alkaline treatment of Dr. Fuller, and the blistering treatment of Dr. Herbert Davies; on the other hand, adopting the opinion of Dr. Bence Jones, that the absence of quinine in the blood was the cause of malarious neuralgia in that disease, the indication is to supply the deficiency. Similar treatment held good in the neuralgia of exhausted nerve-power—that of old age and organic disease. Both diseases were liable to aggravation from intestinal irritation, and neuralgia from that of carious teeth and diseased bone. In both diseases the susceptible condition of the nervous system called for relief by narcotics, etc. Acute rheumatism had frequently been observed to follow diphtheria, in which case it was important to ascertain that the urine was free from albumen before adopting blistering treatment. Assuming that there was excess of fibrine in the blood in diphtheria as well as in rheumatism, the cantharides had been found to check elimination and aggravate symptoms, the cardiac complications especially. In this form of rheumatism, iodine and iodide of potassium were specially advocated.

Dr. WADE had seen two or three cases of acute rheumatism following immediately after diphtheria, and apparently dependent upon imperfect urinary elimination. They were speedily relieved by restoring the urinary secretion.—Dr. ALTHAUS, whilst agreeing with Mr. Hovell in many points, could not do so when he said the neuralgia was due to a deficiency in the blood of some element necessary to the perfect nutrition of nerve-structure. He (Dr. Althaus) believed it was frequently due to a local anæmia of the nerve, and a great many other causes. Certainly the extraordinary effects which occasionally followed the application of local remedies could not account for the deficiency of some important element in the blood. At the same time, as neuralgia appeared in persons who were apparently in good general health, there must be something more than a local cause present in the system which determined the neuralgic attacks.

*On Paralysis of the Bladder, and its Treatment by the Constant Galvanic Current.* By JULIUS ALTHAUS, M.D.—In this paper, the author, after referring to some important researches on the physiology of micturition, lately made by Professor Budge of Greifswald, entered into the pathology of paralysis of the bladder. He eliminated from this affection all cases of mere atony of the viscus from over-distension owing to organic obstructions, such as stricture of the urethra and hypertrophied prostate and other causes; likewise all cases of incontinence of the urine, which was generally ascribed to paralysis of the sphincter of the bladder. Real paralysis of the bladder was, according to Dr. Althaus, only observed (a) when the conduction of nervous influence from the cerebral peduncle to the viscus was interrupted; (b) when the lumbar portion of the spinal cord was diseased; and (c) when the normal excitability of the motor or sentient nerves of the bladder was pathologically altered, without any central affection being present; most cases of this latter class being of the kind termed reflex or inhibitory paralysis. After reviewing the treatment generally adopted for this condition, the author expressed the opinion that, both in efficacy and quickness of action, the constant galvanic current, properly applied, was superior to all other remedies used for this affection. He then described the best mode of applying the current in such cases, and concluded by relating three cases illustrative of the different varieties of the complaint. One of these was owing to syphilitic disease of the cerebral

peduncle; another occurred in a hysterical patient; and the third arose from disease of the lumbar cord. In all these cases, the paralysed bladder recovered rapidly under the influence of the constant galvanic current.

Dr. FELCE related two cases of paralysis of the bladder successfully treated by faradisation.—Dr. ALTHAUS classified the two cases as being instances of reflex or inhibitory paralysis, which in the absence of central lesions would yield to the induced current.—Dr. RADCLYFFE HALL asked whether locomotor ataxy was not occasionally induced by causes such as were present in the cases mentioned.—Mr. HEARDER inquired whether slow intermittence of the induced current was equally valuable with the use of the constant current; and alluded to cases of spermatorrhœa and enlarged liver treated by the same means.—Dr. ALTHAUS replied at length to the various speakers.

*Koumiss, a Dietetic Remedy.* By V. JAGIELSKI, M.D.—Koumiss, though not a specific for any disease, was a benign agent in medicine which merited the serious consideration and study of the profession in both private and hospital practice. By its use the digestive organs were roused into activity, the skin became moist and normal in its functions, the flesh became plump, and the complexion assumed freshness and colour. If the circulation had been abnormal it became regulated, and coldness of the extremities gave place to a pleasant warmth, the dull eyes assumed expression, the depression of spirits gave way to animation, and the respiration acquired more depth and regularity, as had been determined by the spirometer. Large doses had the effect of promoting a feeling of laziness, and even sleep; but this sleep was of the most refreshing kind.

*The Lesions of Enteric Fever as an occasional Cause of Permanent Injury to Nutrition.* By T. CLIFFORD ALLBUTT, M.D.—The author drew attention to the convalescence from enteric fever, which was well known to be often very tedious; and he raised the question whether the specific lesions of that disease, affecting as they did the instruments of absorption, might not sometimes be the cause of permanent marasmus. In enteria, the local mischief not only fell upon the patches of Peyer in the ileum, but spread itself throughout the network of the mesentery. If a rat were fed upon tallow-candles and then killed, the presence of the fat in great quantities in the mesenteric system and glands showed how active was that system in taking up this element of nutrition. Any disease, therefore, which interfered with this system, like enteric fever within it, or chronic peritonitis outside it, would have its visible effect in hindering the absorption of fat, and in preventing the laying on of adipose tissue. These considerations occurred to the author in consequence of his advice being sought in several cases of marasmus, pure and simple, without local disease, without fever, and without adequate loss of appetite. In all of these a severe attack of enteric fever had preceded the marasmus. The patients who were almost denuded of all adipose tissue had, previously to the attack of enteric fever, been in good health. The only explanation which he could give of these cases was, that the fever had acted upon the fat-collecting system in the way already pointed out. The notes of six cases of this kind were then read, but in one of these the marasmus had been preceded, not by enteria, but by a protracted affection of the bowels improperly named dysentery.

*Tumour of the Middle Lobe of the Cerebellum.* By J. HUGHLINGS JACKSON, M.D.—This case was observed in the London Hospital by the author and by Mr. Stephen Mackenzie. There was found, on post mortem examination, a tumour of the middle lobe of the cerebellum, which had pressed on the corpora quadrigemina and on the veins of Galen. There was also a small tumour of the right corpus albicans. Much fluid was found in the cerebral ventricles, and the horns of the lateral ventricles were greatly dilated. The chief symptoms during life were—(1) enlargement of the head, (2) double optic neuritis, and (3) reeling gait, followed by permanent rigidity of the legs and paroxysms of convulsions somewhat like those of tetanus. These seizures, the author supposed, furnish some evidence in support of the view that the changes in tetanus are in the cerebellum. The author referred to cases of a like kind, and particularly to one by Dr. Gull and to one by Mr. Waren Tay, in which a like diagnosis had been made.

*On the Nervous Origin of certain Cutaneous Affections.* By J. F. PAYNE, M.B.—Certain affections of the skin were more or less generally acknowledged to be governed in their distribution by the distribution of nervous structures, and were therefore presumably due to some abnormal nervous activity. Among these were more especially noticeable herpes, or herpes zoster, and that peculiar local induration of the skin called morphea. In a case of each of these complaints, described in the paper, the cutaneous manifestations were associated with affection of the motor part of the nervous apparatus. In a case of herpes in a child, affecting the right lower extremity, and corresponding to the superficial branches of the anterior crural nerve, the appearance of the

eruption was preceded for three days by temporary hemiplegia of the same side. The other case was that of a child suffering from hemiplegia, with some permanent contraction and occasional spasmodic movements of both the upper and lower limb, and in whom part of the skin of the face of the same side was affected with local scleroderma or morphea. The skin of this part was hard and white, neither raised nor depressed; and the alteration was thought to be confined to those parts of the integument supplied by the superficial branches of part of the fifth cranial nerve. In both these cases the peripheral nervous affection giving rise to the skin-disease appeared to be dependent on some morbid condition—in the one case temporary, in the other chronic, of the nervous centres; and that this explanation might be applicable to other cases.

*On Intemperance as a Cause of Chronic Bright's Disease.* By WM. ROBERTS, M.D.—The generally received opinion, that the abuse of alcoholic liquors is a frequent cause of Bright's disease, has been called in question by Dr. Dickinson in an elaborate argument in his recent work on *Albuminuria*; and the scope of the paper was to examine the evidence Dr. Dickinson relied on in coming to an opposite conclusion. The writer endeavoured to show that the pathological facts adduced by Dr. Dickinson were either untrustworthy, or that they had been incorrectly interpreted. Dr. Roberts especially pointed out the fallacy of the argument drawn from the Registrar-General's Reports. It was quite true, as Dr. Dickinson had stated, that the districts which yielded the largest returns of deaths from intemperance did not return an excessive proportion of deaths from Bright's disease; but exactly the same result was obtained when the same statistics were applied to the mortality from cirrhosis of the liver—a disease which is notoriously and chiefly the product of intemperance.

*The Respiratory Movements in Man.* By ARTHUR RANSOME, M.D.—The paper recorded observations made with Dr. Burdon Sanderson's stetho-cardiograph as to the order of movement of the ribs in ordinary and forced breathing in males and females; and also measurements of the movements of different points in the chest-wall, made simultaneously in three planes by means of the author's stetho-metrometer constructed for the purpose. From these measurements conclusions were drawn as to the mode in which the several movements were produced, and variations in the extent of movement in different directions were pointed out in the two sexes at different ages, and in different positions. The influence of various muscular power was shown, and the variety produced by different diseases, especially phthisis, pleurisy, and emphysema.

#### SECTION B.—SURGERY.

*On Excision of the Tongue.* By GEORGE SOUTHAM, F.R.C.S.—After making some remarks on cancer of the tongue, Mr. Southam referred to the difficulty which surgeons frequently experienced in excising the entire organ, or even a large portion of it, for this affection. The safest mode of removal was by the aid of the *écraseur*, but this instrument frequently failed to effect the purpose, in consequence of the shape of the tongue and the peculiar arrangement of its muscles, causing the chain of the *écraseur* to slip towards the diseased portion, in which it often became imbedded before the operation was completed. Some cancerous deposit was therefore left, and, though it might not be in sufficient quantity to interfere with the healing of the wound, usually led to an early return of the affection. To remedy this defect in the operation, Mr. Southam had had constructed a pair of forceps with a movable hinge, which completely grasped the tongue at its root, and confined the action of the *écraseur* to the part where it was first applied. A case was described in which, with this instrument and the *écraseur*, and without making an opening in the floor of the mouth to pass the chain through, the tongue, of which the body was affected with cancer, was excised beyond the foramen cæcum and circumvallate papilla, these structures being included in the separated portion.

Mr. CHARLES STEELE remarked on the great advantage which was gained by not being compelled to open the lip, chin, and symphysis menti, thereby lessening greatly the severity of operation and risk of inflammation of the lungs, etc. He asked the results of Mr. Southam's operations.—Mr. LUND said the great value of the instrument was, that it fixed and dragged forward the tongue to a degree which no other would do.—Mr. FURNEAUX JORDAN thought that the instrument would prove of service. He asked if Mr. Southam had used two *écraseurs*, one over the dorsum of the tongue, and the other under the tip. There was a danger of hæmorrhage in using the *écraseur*, for which surgeons must always be prepared.—Mr. MAUNDER said that, to effect the operation without hæmorrhage, the chain should be worked slowly, once in the minute. The pain was less than might be supposed, and

almost ceased when the chain was drawn tight.—Mr. S. GAMGEE spoke of the great value of Mr. Southam's instrument, and of drawing the tongue well forward. He narrated a case in which he drew the tongue well forward with Marshall's polypus forceps, and cut off the organ; and, to stop hæmorrhage, filled the patient's mouth with ice. Mr. Gamgee also remarked that tumours might be freely removed from the neck of the uterus with the knife, ice being immediately applied; and that the great danger of the *écraseur* was its liability to slip.—Mr. SOUTHAM, in reply, said he had used his instrument once for removal of the whole tongue, almost touching the epiglottis; also for removal of small portions of the tongue. The recovery has been rapid. He agreed with the remarks about hæmorrhage and the *écraseur*; and that a surgeon should be prepared to apply ice, or tie any artery. With his instrument, two *écraseurs* could not be needed. Mr. Southam would be happy to receive any suggestions for the improvement of his instrument.

*Antisepsity in Surgery.* By EDWARD LUND, F.R.C.S.—It was argued by the author that antisepsity might be brought about by any means through which the *excreta* of wounds were protected from putrefactive change, and the surfaces on which they rested preserved from contact with the irritating chemical products thus elaborated. In recent wounds, the strict observance of antisepsity saved much constitutional distress, tended to keep the tissues from loss of substance by sloughing and ulceration, and the patient's strength from being reduced by needless suppuration. But, in healing wounds, it was admitted that greater time would be often required to complete a perfect cicatrix; although this, when formed, would be more pliable and natural than under other modes of treatment. The claims of many antiseptics were considered, but preference was given to carbolic acid in very weak solution, or in that form of composition which Mr. Lister had described as his carbolicised muslin, a modification of the antiseptic cere-cloth, first proposed by Mr. Lund at the meeting of the Association at Leeds in 1869.—The PRESIDENT (Mr. May) said that the antiseptic plan of treatment was adopted at the Royal Albert Hospital, Devonport, with satisfactory results.

*On the Extension of Inflammation from the Epididymis to the Urethra.* By FURNEAUX JORDAN, F.R.C.S.—Mr. Jordan remarked that inflammation of the prostatic urethra from any cause (injuries, foreign bodies, operations, adjacent inflammations, and all urinary obstructions) may extend to the epididymis. It would be an original investigation to discover any kind of prostatic inflammation that did not extend along the submucous connective tissue of the vas deferens. He was not aware that any one had observed the converse of this. He had recently watched a case in which inflammation unmistakably travelled from the epididymis to the urethra. A married man, free from disease and the history of disease, was admitted into the Queen's Hospital suffering from the effects of a severe blow on the scrotum. On the subsidence of scrotal swelling, the left epididymis was found to be enlarged, painful, and tender. The next day, the adjacent portion of vas deferens was swollen to the size of a goose's quill, and tender to near the inguinal ring. The following day, the swelling extended into the ring. A few days later, a slight urethral discharge appeared, and all the symptoms of a mild urethritis. Mr. Jordan believed any new fact to be of value which would help to explain obscure urethral discharges.

Mr. LUND observed that the history was the important point in such cases. He mentioned the case of a young man who, when skating, felt something crack in his groin; orchitis resulted, and was followed by slight urethritis.—Mr. MAY's experience confirmed Mr. Jordan's, that urethritis need not be considered as a necessary result of gonorrhœal infection, but that it did follow stricture.—Inspector-General LONGMORE considered the case most valuable and practical.—Mr. STEELE asked how many days the patient was in hospital before urethritis occurred. This would be of value in diagnosis, by enabling a comparison to be made with the time of incubation of gonorrhœa.—Mr. F. JORDAN, in reply, said that it is not necessary to presume gonorrhœal infection, even in spite of the positive assertion of patients; cases of urethritis might depend upon other causes. The case, having occurred only this year, was not of sufficient duration to show after-results. Mr. Jordan corroborated Mr. May's statement with regard to orchitis or epididymitis occurring after stricture or passing instruments. It was difficult to draw a distinction between gonorrhœa and simple urethritis. In reference to Mr. Steele's question, he answered that the ordinary incubation of gonorrhœa might be five days, whereas the man was in hospital ten days before urethritis occurred.

*Case of Excision of the Scapula.* By CHARLES STEELE, F.R.C.S.—Charles Bees, aged 8, was admitted on April 14th into the Bristol Royal Infirmary, on account of a large swelling upon the right scapula, which had been forming only six weeks, and had enlarged very

rapidly during the last fortnight. The tumour covered the whole surface of the scapula except the inferior angle, and encroached over the upper border towards the clavicle; it was firmly adherent to the scapula, most prominent over the spine, and had a highly elastic and, in parts, fluctuating feeling. The child had fallen off in flesh slightly, and looked rather delicate. Mr. Steele made an exploratory incision, and removed a minute portion of the substance, which on microscopic examination showed large, almost square, cells filled with secondary cells. Extirpation of the scapula was decided upon; and, on the 18th, after making a free incision down to the bone through the tumour to confirm diagnosis, Mr. Steele made a free elliptical incision from the upper border to the inferior angle, carefully surrounding the first incision, so as to avoid infiltration. He then slipped the inferior angle of the scapula from under the latissimus dorsi, divided the muscles attached to the posterior and anterior borders, freed the subscapularis muscle from its surroundings, divided all connections of the clavicle and humerus close to those bones, and, by very delicate dissection, cleared the projections of the tumour from their close proximity to the subclavian vessels, etc. The suprascapular, posterior scapular, and subscapular arteries, and one muscular branch, were secured. The forearm was supported across the chest, and a compress of wool applied over the excavated cavity. The tumour had evidently sprung from the bone; it covered its dorsum, infiltrated its tissue, formed a large firm projection on the venter, and had stretched the supraspinatus, infraspinatus, and subscapularis muscles as a capsule enclosing it. Recovery steadily progressed till the seventh week; the wound was then nearly healed, the child ate well, had gained in flesh, was able to be up all day and go into the garden, and looked well. Two nodules of encephaloid now recurred, and were removed entire, the intercostal muscles being cleaned in doing so. Ten days afterwards, a fresh nodule formed near the spine; and the granulating surface of the wound became so infiltrated that all hope of further removal had to be abandoned. It was some satisfaction to notice that all recurrence of disease was in the lower part and towards the spine. Mr. Steele remarked that this case showed clearly two points: first, that the operation was well borne by the system, and recovered from; and, secondly, that even before cicatrization was complete, a surprising amount of movement existed in the arm. The hand and forearm could be freely used, and the arm drawn well forwards, also extended from the side, and even drawn backwards by the latissimus dorsi muscle. This showed that, had disease not returned, a very useful limb would have resulted.

Mr. F. JORDAN congratulated Mr. Steele on having performed the operation, but said the only points to question were whether disease should in such a case be removed at all, and, if it were, whether the whole upper limb and clavicle should not be also removed.—Mr. ALFORD said that the case involved the question whether any cancer except epithelioma should be removed, as it was most likely to return in a more intractable form. Scirrhus, for instance, usually, in five or six years was more rapid in progress, more painful, and opened soon.—Mr. MAY remarked that anæsthetics now enabled tumours to be removed which, thirty years ago, must have been left on account of the pain which their removal would have caused.—Mr. STEELE, in reply, said that, as he had stated, the tumour was encapsuled, and was removed entirely surrounded by sound tissue. Had even the whole arm and clavicle been taken away, the parts in which disease returned would have remained. If cases for operation were wisely selected in various cancers, very happy results frequently occurred. With regard to this special case, having seen the boy very recently, he was sure disease now was not so extensive, nor the boy's system not so much reduced, as it would have been had the cancer been left to itself.

*The Treatment of Aneurism by Compression.* By RAWDON MACNAMARA, M.D.—[Dr. Macnamara's paper was published in last week's JOURNAL.]

Dr. BRATY explained the use of the instruments for compression invented by the late Dr. Todd.—Deputy Inspector General LONGMORE, C.B., made some remarks on the partial interruption of the current of blood through the artery, and pointed out that the total arrest of the flow of blood frequently defeated the end in view. He also adverted to the intelligent co-operation of the patient; and related the case of a soldier who, suffering from aneurism, had explained to him the process of cure and how it was to be obtained. The soldier applied compression to the artery by means of a soda-water bottle, and cured himself. He spoke in high terms of the value of Dr. Carte's instrument, and stated that cases of aneurism had been cured by its means which had apparently been impossible. He thought that Dr. Macnamara was rather of opinion that the cure of aneurism by compression was not well known in England. In the army, however, where there were a large number of Irish surgeons, its value was as well understood; and thus had a remarkable number of cures by this means. In one ship alone, three

cases were cured by compression.—Mr. C. HEATH asked if the number of hours referred to the continuous treatment by day only, not including the night. He referred to a pamphlet by Mr. O'Ferrall, who advised that a tourniquet should be placed above and below the aneurism, and wished to know if that practice was carried out.—Mr. R. H. MEADE related cases in which compression was used, and the current entirely stopped, and then entirely intermitted, when cures were obtained.—Mr. HECKSTALL SMITH thought he had seen the earliest case in England under the care of Mr. Guthrie in 1827, and was surprised that a record was not made of it. The pressure was kept up intermittently by a large door-key covered with leather, by relays of students. A cure was effected.—Mr. KEMPTHORNE asked if compression by fingers was not preferable to any other contrivance.—The REV. DR. HAUGHTON wished to mention that, some years ago, an inquiry was made in the University of Dublin into Dr. Carte's invention; and the degree of M.D. was conferred upon him for his invention. He thought that the English Universities might imitate the example of the Irish.—Mr. MAUNDER thought that the digital method was preferable to the instrumental. Many years had elapsed since he saw a femoral artery tied for popliteal aneurism. He was in favour of digital compression.—Dr. MACNAMARA, in reply, stated that his great object was to exhibit the instruments used by Irish surgeons. He thought that compression by instruments was the best, as it could be placed directly on the artery, and the force regulated. Constant pressure was obtained by instruments; whereas, if digital compression were relied upon, there must be occasional cessations of pressure by the students. He knew that if the pressure of more than nine pounds were required to stop the pulsation, the patient must be reduced.

*Notes on Ambulances.* By WILLIAM MAC CORMAC, F.R.C.S.—Mr. Mac Cormac explained that he was called upon to undertake the charge and treatment of upwards of one thousand cases of gun-shot wound within the space of twenty-four hours. The ambulance of which he was in command having by rare good fortune arrived at Sedan a day or two before the great battle, and as there were only the military surgeon and the assistants in the town when he arrived, he and his assistants were warmly received. During the whole of the fight, they were directly under fire; and all the day, and far into the night, he was engaged in performing operations as fast as he could. The wounded were brought on stretchers, which, although requiring many men to carry them, was a preferable mode of conveyance to any other, as far as the wounded themselves were concerned. Ambulance-waggons hitherto used had been imperfect, and often unable to get into the field at all. In the large number of wounded with which he had to deal, he did not find a single case of primary hæmorrhage. Cases where large arteries were injured must have nearly all died on the field. They had also had but few head-injuries. The operations were chiefly excision of the shoulder and elbow, including the hip and shoulder joints; and the result showed the impracticability of following the wholesale lessons of that conservative surgery practised in British hospitals. Ample use of carbolic acid was highly desirable. He endorsed the importance of primary rather than secondary amputations, and was sorry that in Plymouth, where Mr. W. P. Swain had earned a high reputation for his work on *Excision of the Knee-joint*, he could say nothing in favour of this operation. In gun-shot wounds received in action, it was wholly inapplicable. A very distinguished German surgeon performed it thirty-six times; thirty-five of the patients died soon, and the thirty-sixth required amputation of the thigh.

Deputy Inspector-General LONGMORE remarked that to Mr. Mac Cormac, and to his coadjutor, Dr. Frank, was due all the credit for the good conduct of the ambulance under their care. They had done much to save the credit of the International Society. There were great difficulties in connexion with international aid; and it still remained to be seen how far it could be carried out. If a large number of neutrals were engaged in taking care of the wounded of belligerents, it had a tendency, he considered, to increase the wounded; for, if an army were not hampered by wounded, it was free to go on and fight. He thought no transport was so good as the hand-litter, the difficulty in connexion with which was the obtaining a sufficient number of bearers.—Dr. MCNULTY stated that primary amputations and excision of joints almost invariably failed. The use of carbolic acid by the Prussians was extensive, and was thought to be of immense service, especially in the large abscesses of the thigh after gun-shot wounds. The solution should be 1 to 200, used as an injection. One fault of its use was, that it healed up wounds too quickly. The formation of bed-sores was very frequent, and in them the use of a stronger solution of carbolic acid was most useful.—Mr. W. P. SWAIN hoped yet that, even in the face of the bad statistics, primary excision of the knee-joint might yet be practised.

With the improvements in field-hospitals, giving greater rest to the patient, with carbolic acid, on Watson's anterior suspension splints, he

hoped the practice might yet be adopted.—Deputy Inspector-General LONGMORE remarked that Nussbaum stated that three of his cases of excision had recovered.—Mr. MAUNDER said that the question of primary excision was very important, and he would like to have further information from Mr. Swain on the subject.—Mr. SWAIN states that in civil practice nearly all the cases of primary excision from gun-shot wound had recovered.—Mr. MAC CORMAC, in reply, stated that carbolic acid was of extreme advantage. He was most anxious to try Lister's method; but the length of time required was against it.

*The Treatment of Stone in the Female Bladder.* By CHRISTOPHER HEATH, F.R.C.S.—The paper was illustrated by three cases which had occurred in the author's practice. The first case was in a patient aged 32, who was subjected to lithotomy, a stone weighing four drachms, composed of phosphates, with a nucleus of oxalate of lime, being removed in five sittings with complete success. The second case was in a married woman aged 49, in whom a large stone was readily felt *per vaginam*. Vaginal lithotomy was performed, and a stone of an ounce and a half and measuring two inches by an inch and a half was readily removed, the wound being closed immediately with six silver sutures passed through the entire thickness of both vaginal and vesical wall. The patient made a rapid and complete recovery without the formation of any fistulous opening. The third case was that of a child aged 11, in whom the urethra was rapidly dilated and a small stone extracted, when there was found to be a much larger mass fixed to the bladder, which was removed with difficulty after being partly broken up, the whole mass weighing nine drachms. The child had incontinence for a few weeks after the operation, but eventually recovered complete control over the bladder. Mr. Heath briefly contrasted the three proceedings, maintaining that rapid dilatation of the urethra within certain limits was a perfectly harmless and most useful practice. He advocated lithotomy for moderate-sized stones in the adult, but for large stones preferred vaginal lithotomy with immediate closure of the wound, a proceeding which experience had proved to be remarkably successful.

Mr. MEADE's experience went to show that, as a rule, calculi formed in the female bladder from matter introduced from without. In a case of his he found the nucleus to consist of a piece of carrot, and in another of a bit of bone.—Dr. EVANSON said that in one case two calculi were removed, each containing a molar tooth.—Mr. SQUARE had operated by incision through the urethra, and in another case by lithotomy.—Mr. STEELE was glad to find Mr. Heath speak well of rapid dilatation. It was the practice at the Bristol Infirmary.

*A New Stricture-Dilator.* By BERKELEY HILL, F.R.C.S.—The instrument was described as operating on the principle of Perrière's, Holt's, and Richardson's. The two halves of a split sound, equal when in juxtaposition to the calibre of a No. 2 or No. 3 catheter, could be separated by thrusting between them a segment of a cone fixed to a slender stem, until they occupied a space equal to a No. 12 catheter. The dilation might be carried on to No. 14 or No. 16 of Weiss's scale. The advantages said to be possessed by the instrument were, simplicity and cheapness of construction; absence of necessity for a central guide; and diminution of resistance.

*Loose Cartilages of the Knee-joint and their safe Removal by Subcutaneous Incision.* By W. J. SQUARE, F.R.C.S.—The author stated that, since he published his account of the operation by subcutaneous incision about ten years ago, when he related nine cases, he had performed the operation fifteen times. The twenty-four cases had all been operated on without selection; and all had recovered without drawback. Cases were brought forward illustrative of the dangers incident to the operations by direct and valvular incision; and the operation practised by the author was described. The loose cartilage is conducted to the inner and lower part of the joint and held there by an assistant. A tenotomy-knife having been introduced, the capsule of the joint is freely incised upon the cartilage; the knife is then directed so as to open the cellular tissue over a convenient part of the fascia. The cartilage is now pressed and lifted out of the joint into the cellular bed prepared for it, and slid along for about three inches. It is fixed *in situ* with a firm pad and adhesive plaster, the foot and leg being bandaged up to the edge of the cartilage, and the limb placed in a splint. If no inflammation ensue, the cartilage is excised about a week after the operation. The paper closed with a few remarks on the different varieties of loose cartilage, their structure and origin.

Mr. WM. ADAMS referred to Mr. Square as one of the highest authorities on the subject of the removal by subcutaneous incision of loose cartilages. Very few surgeons would, in the face of the facts brought before them, venture upon direct incision.—Mr. SQUARE, in reply to a question as to whether he fixed the cartilage by passing a needle through

it, and then cut down upon it, said he had done so on two occasions, and found the plan very inconvenient, as there was great difficulty in withdrawing the needle, which stuck firmly.—The discussion partly turned upon the question whether any analogy existed between rheumatism and loose cartilage; and Mr. Square remarked that he did not think so, as townsmen suffered as much as agriculturalists from the former. He was rather inclined to think that loose cartilages were caused by violent use of the knee.—Mr. LONGMORE stated that, during the nine years he had been at Netley, only one case of a soldier suffering from loose cartilage had come before him. This he had treated upon the valvular system; but after hearing Mr. Square's paper, he should not adopt the treatment again.—Mr. W. P. SWAIN thought that rheumatism had something to do with loose cartilages. The agricultural labourers of Devon and Cornwall were very subject to rheumatism, and also to the other affection. He related a case which had come under his own knowledge. A man became afflicted by a loose cartilage in America, where the surgeons wanted to amputate his leg. This he would not have done, and came to England. He was admitted to the Royal Albert Hospital, Devonport; but Mr. Swain being unable to get hold of the cartilage, the man left the hospital, and went to his work. Some time afterwards, the man fell a distance of about sixteen feet, and nearly broke his skull, but he also knocked the cartilage out of the knee-joint, and he (Mr. Swain) was then enabled to extract it.

*The Influence of Nerves in the Repair of Fractures.* By WILLIAM SQUARE, F.R.C.S.—The paper consisted of observations on the mode of separation of the long bones when under the influence of the cerebro-spinal nerves, and also when deprived of such influence. It was based upon the *post mortem* examination of a man who sustained a fracture of the spine, with paralysis of the bladder and lower extremities, and at the same time received a compound fracture of his left forearm, and also of his right thigh; the fractured arm receiving due nervous influence, while the fractured thigh was deprived of it.

*Growths in the Larynx: the Comparative Advantages of Laryngoscopic Treatment, and Direct Incision into the Larynx.* By MORELL MACKENZIE, M.D.—The relative advantages of these two methods must be considered in relation (1) to the quickness of cure; (2) completeness of removal and probability of recurrence; (3) danger to life; and (4) restoration of voice. From an experience of one hundred cases treated, a month was estimated to be the average duration of laryngoscopic treatment. External treatment, on the other hand, required only a fortnight. As regards the second question, complete removal was able to be effected in 97 per cent. of the cases which underwent the full course of laryngoscopic treatment, and recurrence took place in about 7 per cent. In 28 cases of direct incision, collected from all sources, 10 died in a short time; and in the remaining 18, the growth was incompletely removed in three cases, and recurrence took place in three cases, or, in other words, in 20 per cent. No death occurred in the laryngoscopic cases; whereas of the 28 treated by external operation, 3 immediately terminated fatally, 6 died at the end of a few months, and 1 from an independent disease. With reference to restoration of function, perfect voice was regained in 77 per cent. of those who underwent laryngoscopic treatment, and a more or less serviceable voice was restored in 16 per cent. Of the 18 cases who survived direct incision more than a few months, only 9\* completely recovered their voice, 4 had persistent hoarseness, and 6 permanent aphonia. Consideration of the above statistics established the paramount value of laryngoscopic methods of treatment, and justified one in saying that extra-laryngeal treatment ought never to be adopted unless there were danger to life from suffocation or dysphagia.

*On Injuries of the Axillary Artery occurring in Artillery Practice.* By WM. R. E. SMART, M.D., C.B., Inspector-General Royal Navy.—Dr. Smart cited three cases of injury of the axillary artery resulting in gangrene, caused by violent throwing back of the upper extremity when explosions take place in the act of loading cannon. He considered that this peculiar injury occurred when the explosive force had not been of the highest degree, as he had never known an injury to occur at the shoulder where the hand had been blown away. These cases showed that the proper treatment at the seat of vascular injury was, by cold or other means, to ensure early coagulation and fibrination of the clot, which happened successfully in two of the cases cited, and not to delay amputation at the middle of the upper arm as soon as gangrene had begun at the fingers.

\* These cases are tabulated in the Thyrotomy Table in the author's essay on *Growths in the Larynx*. In this table, however, the result of Case 27 was entered as "not stated"; but since the publication of the volume Dr. Solis Cohen had informed the author that the result was "complete restoration of voice."

*The Unity of the Syphilitic Virus.* By S. MESSENGER BRADLEY, F.R.C.S.—Mr. Bradley commenced by stating that, in order to demonstrate the unity of the syphilitic virus, it was requisite to produce a soft non-infecting sore by direct inoculation from a hard infecting chancre upon a virgin subject. He had performed many experiments upon monkeys, guinea-pigs, and kittens, with the result of producing a characteristic soft chancre in three instances by direct inoculation from an infecting sore, the virus being taken prior to cicatrization. In each case, the chancre from which the virus was taken was accompanied by multiple inguinal adenopathy, and other evidences of constitutional infection; in each case, the inoculated sore appeared within a few days after the introduction of the matter; in each case it suppurated freely, was capable of auto-inoculation, and inoculation upon fresh animals; in no case were there constitutional symptoms at the termination of three months. Mr. Bradley alluded to the fact that this conversion of one form of syphilis into another (in many respects a very different one) did not commonly occur, and drew a parallel between the history of syphilis in this respect, and the history of the vegetable parasites, which were all confessedly interchangeable, but which, as a matter of observation, very rarely underwent this mutual change.

### SECTION C.—MIDWIFERY.

**THE PRESIDENT (Dr. BEATTY),** on taking the chair, said this was the second time he had had the pleasure to preside over this section. The first time they did him the honour was in 1867, when the Association held its meetings. He believed that was the first meeting at which the sections were adopted. It was then tried as an experiment, and he was pleased to know it had been found to answer successfully at subsequent meetings.

*The Treatment of Hemorrhage arising from Retention of the Secundines after Abortion.* By J. G. SWAYNE, M.D. [This paper was published at page 201 of last week's JOURNAL.]—A discussion followed, in which the President, Dr. Barnes, Dr. Wynn Williams, Dr. H. Bennet, Dr. Aveling, Mr. Greenway, Mr. T. E. Owen, Mr. Goodridge, Dr. Braxton Hicks, and other members took part.—Dr. BARNES advocated the injection of solution of perchloride of iron (one ounce to twelve).—Dr. BENNET recommended plugging the cervix uteri with cotton; and Dr. BEATTY spoke favourably of the introduction of laminaria tents.

*Fibro-Cystic Disease of the Uterus.* By T. E. BEATTY, M.D.—The author submitted to the section a recent specimen which exhibited the mode of formation and growth of this important complication of fibroid disease. The case was one in which Dr. Beatty had been consulted in Dublin, and which had been tapped three times, and dark-coloured albuminous fluid had been removed by the aspirateur at each operation. When Dr. Beatty saw the patient, which was a week before her death, he found the abdomen occupied by an uniform tumour, very much resembling a gravid uterus, at the eighth month of pregnancy, in size and shape. On pressing deeply, distinct fluctuation could be felt, and the walls of the cavity gave the impression of being thicker and more fleshy than those found in ovarian dropsy. The uterus, when examined by the finger and sound, appeared healthy, and of the normal size; but it was fixed in its position, and could not be moved. Dr. Beatty declared his opinion that the case was one of fibro-cystic disease of the uterus. The third tapping was performed after this, and the woman died of peritonitis in a few days. A post mortem examination had verified the opinion that had been given; and Dr. Beatty was happy to be able to show the specimen to the members of the British Medical Association, as the means of diagnosis of this disease were still very imperfect, and it was necessary to bear in mind the possibility of its occurrence in all cases of tumour existing in the abdomen.—Dr. Beatty called the attention of the section to the recently published case of removal of a large fibroid from the fundus of the uterus by operation, by Mr. Spencer Wells, in which the woman recovered; and said that a similar operation, if performed upon the subject of the case just detailed, might have been followed by success; but no one could have foretold the smallness of the connection between the tumour and the uterus during life.

*The Treatment of Cancer of the Neck of the Uterus and allied Structures by the injection and application of Bromine.* By A. WYSS WILLIAMS, M.D.—The author commenced by making some remarks on the spontaneous removal of malignant tumours, from the study of which he was led on to the injection of bromine into cancerous tumours of the uterus and other parts. The eight cases published in the last volume of the *Gynaecological Transactions* will be continued well. He entered into details as to the manner of injecting these deposits, and the care required in the use of bromine both as an injection and application, stating that

before its use the surrounding parts should be well protected by a solution of soda. He exhibited the various instruments made for the injection, etc., of bromine. He gave the history and successful treatment of a selected case of medullary carcinoma of the uterus in the state of disintegration and ulceration by this method; and also the particulars of a case of epithelioma of the lower lip, which had been previously removed by operation. On the return of the disease the patient was sent to Dr. Wynn Williams, who by two injections of bromine caused the entire, and so far permanent, removal of the disease.

*On Hysteria and its various Interpretations.* By E. J. TILT, M.D.—Dr. Tilt began by remarking that writers on hysteria might be divided into two groups: a comparatively small group of writers who owned they knew nothing of diseases of women, and nevertheless affirmed that uterine affections had nothing to do with hysteria; the adverse opinion being held by the great majority of those who thoroughly understood diseases of women. The author quoted from the lectures of Dr. King Chambers, Dr. Russell Reynolds, Dr. Handfield Jones, and Dr. Hyde Salter, to show what was taught respecting hysteria by those who know little of diseases of women. He proceeded to show how this ignorance of diseases of women by the leaders of the profession and by lecturers in public schools injuriously affected their own interests, the welfare of their patients, and the advance of medicine. Dr. Tilt objected to hysteria being identified with lust, and to the common practice of calling hysterical all inexplicable symptoms occurring in women. Lastly, the author explained hysteria to be the product of an indispensable predisposition to emotion on the part of the nervous system, and some determining cause; this determining cause being sometimes one of those debilitating agencies that intensify all nervous affections; sometimes the cause being a disturbed action of one of the abdominal viscera, the reflex centres of our emotions; diseases of menstruation, in which slight structural diseases of the ovary find expression, and the mildest forms of uterine disease, being given as the most frequent determining causes of hysteria. Dr. Tilt concluded—1. That our hospital men, to be efficient lecturers and leaders of the profession, should be thoroughly acquainted with diseases of women; 2. That, whenever it was a question of hysteria, the state of menstruation should be carefully ascertained, and the sexual organs accurately examined, if they presented signs of disease; 3. That the best way for neurologists to disperse the clouds that still obscured our knowledge of hysteria, catalepsy, and epilepsy, was to study the pathology of the ganglionic nervous system.

*Hypertrophied Elongation of the Cervix Uteri.*—Dr. BARNES exhibited and explained a drawing made from a preparation recently put up at St. Thomas's Hospital, which showed the anatomical relations of hypertrophy of the cervix uteri. The specimen, he believed, was unique in its completeness and accuracy, as the whole pelvis was included, and the contents were preserved without disturbance. The length of the uterus was seven inches; the two tips of the os uteri were much hypertrophied and everted. The everted vagina covered the protruded mass. The retro-uterine peritoneal pouch was extended externally to the vulva, and the base of the bladder was sacculated.

*Oxytocics.* By R. BARNES, M.D.—The author pointed out that the notion that iron was an abortifacient was unfounded.

*On the Value of the Sulphate of Iron as a Local Application in Phlegmasia Dolens.* By R. W. CRIGHTON, M.D.—This method of treatment was first adopted by the author many years ago, from the great success reported by Velpeau from its use locally in erysipelas. It had been employed exclusively in that form of phlegmasia dolens commencing at the calf of the leg and extending upwards to the groin, where the veins are chiefly involved. It had been applied as a lotion (twenty or thirty grains to one ounce of water), as hot as the patient could comfortably bear it, generally by means of spongio-piline. All the cases so treated had made good and rapid recoveries, contrasting favourably with cases formerly treated by leeching and ordinary hot fomentations. Murated tincture of iron was, at the same time, given in large doses. The same method of treatment was suggested in other cases of phlebitis. The action of these remedies was referred to their power of controlling vascular dilatation, and also to their antiseptic powers.

*The Radical Cure of Retroflexion of the Uterus.* By T. E. BEATTY, M.D.—The object of the paper was to show that a vaginal pessary might give relief by supporting the entire uterus; but that it could not effect the restoration of the natural shape of the organ by obliterating the vicious bend which it had acquired. That could only be secured by straightening the uterus by means of the sound, and keeping it straight by a stem passed into its cavity, and retained there by some means that would not confine the uterus in a fixed position, but would leave it free to move in

the pelvis according as the rectum and bladder were full or empty, or the woman was in the upright or in the horizontal position. Dr. Beatty proposed in 1862 to employ Sir James Simpson's uterine stem, with a bulb at the bottom, which, being passed into the uterus, he retained in its place by a flat smooth boxwood pessary introduced after it, which permitted free motion of the bulb over its surface, yet prevented the stem from escaping. These were to be worn for six or eight weeks, and required no removal or change during that period; and the woman went about her ordinary occupation as if no instrument were there. When the bend had been removed by this means, at the end of the time specified they were to be removed, and a simple ring of gutta-percha, of the same diameter as the boxwood pessary, was to be introduced into the vagina, which assuming the sloping position that a flat pessary always did in the vagina, supported the fundus of the uterus and prevented any attempt at falling back, while the lower part of the body and the cervix were allowed to hang down through the ring, and thus the natural position of the uterus was preserved. As such a ring did not interfere with any of the functions of the vagina, it might be worn for six months or longer, and then removed, when the uterus would keep its proper shape.

*The Treatment of Fibroid Tumours of the Uterus.* By ALFRED MEADOWS, M.D.—The author combated the notion that these growths could be in any way diminished in size, still less cured, by any known therapeutical agent. Discussing the question from a histological point of view, he felt convinced that it was impossible to procure the absorption of any part of the solid constituents of these tumours; at the same time, he showed that there was ample scope for the exercise of skill in the medical treatment of such cases, especially in regard to hæmorrhage and pain. The chief object of the paper was to advocate more frequent resort to surgical treatment. The author expressed his belief that much more might be done in many of these cases than had been hitherto. Even in the subperitoneal variety, he thought that, in cases where much distress existed, abdominal section ought to be resorted to more frequently; while in the interstitial and submucous forms, it ought to be the rule in practice always to endeavour to assist Nature in her method of cure—viz., by expulsion. For this purpose, three objects should be kept steadily in view. 1. All obstruction should be removed by freely dividing the cervix in several directions. 2. The tumour should be separated from its attachments, not necessarily all at once, but by successive stages. 3. As far as possible, continuous uterine action should be maintained by the administration of ergot and other oxytocic agents. A case was cited in illustration of the value of this combined method of treatment.

*A Rare Form of Post-partum Hamorrhage.* By J. BRAXTON HICKS, M.D., F.R.S.—After quoting the remarks of Dr. Blundell when speaking of the diagnosis of a second foetus relative to the falling down of the membranes in front of the os uteri, and the consequent retention of blood within the uterus and the protrusion of the bag of membranes, Dr. Hicks brought forward three cases in which the membranes, having remained adherent all round the lower portion of the uterus, and a detachment of the edge of the placenta situated on the side having taken place, a quantity of blood was effused, pushed down the inverted membranes through the os into the vagina, and, the uterus meantime filling, a large amount of blood thereby accumulated, sufficient to produce very serious symptoms. The treatment was indicated, and some few remarks made on the expulsion of the placenta.

*Reduction of Inversion of the Uterus.* By J. BRAXTON HICKS, M.D., F.R.S.—Dr. Hicks described four cases of acute, and two of chronic inversion of the uterus, with remarks upon the causation, prevention, and treatment. He showed some pessaries and apparatus whereby to apply pressure more certainly in the chronic forms, a simple form of which he had found successful.

*Supplemental Mechanical Force during Parturition regulated by a Dynamometer.* By PROTHEROE SMITH, M.D., Senior Physician to the Hospital for Women, etc.—After some allusion to the physiology of labour and to the agents of force exercised in parturition, viz., that of the voluntary and involuntary muscles, Dr. Protheroe Smith spoke of the injurious consequences when the normal balance of these powers was disturbed, specially marking the distinction between the capabilities of the uterus and of the muscles of the trunk, to obviate which, as well as to subsidise the power at fault, he advocated the judicious employment of an artificial force, according to certain rules, by means of his "obstetric pelvic band", which was described and exhibited. The peculiarity of this instrument was that it formed with the pelvis itself, as it were, a solid basis, which, by virtue of its immobility, allowed the accoucheur easily to employ the required aid to assist and expedite expulsion, and so, by following the natural movements, manifestly to shorten the period of labour, and to lessen its risks. This was regulated by a dynamometer, described and illustrated by a drawing. It was so constructed as to

measure and record accurately the force employed, imitating the normal parturient throes when wanting, especially by interrupted efforts like those constituting the compound character of such pains. In demonstration of this, Dr. Protheroe Smith gave a case of labour in which such means were employed with the result. In this, each pain, as well as the amount and duration of every artificial effort, was recorded, and some valuable calculations and observations were appended from the pen of Professor Haughton of Dublin, from which it appeared that the force used in parturition was much greater than was generally supposed by obstetricians.

*A Successful Method of Treating Certain Cases of Dysmenorrhœa and Sterility.* By PROTHEROE SMITH, M.D., Senior Physician to the Hospital for Women, London.—After giving the pathology of obstructive dysmenorrhœa with the usual mode of treatment, Dr. Protheroe Smith called attention to that of dilatation by bougies, suggested by Dr. Mackintosh, and the modification of it by Dr. Simpson, and his operation of incision of the cervix by the hysterotome. Dr. Protheroe Smith's experience having suggested a doubt of the advantage of this practice, he was led to adopt the plan he now advocated in certain cases indicated by conditions which he mentions. To overcome the stricture of the os internum, he used *extension-force* by means of his uterine dilator, an instrument described and exhibited, as being peculiarly suitable to this purpose. To restore the os tince to its natural form, per speculum, he incised it laterally at the commissures of the labia. Particular instructions were given for this treatment, which, during the last twenty-five years, he had employed with considerable success in remedying both obstructive dysmenorrhœa and sterility. Six cases were cited in illustration.

*The Treatment of certain Cases of Placenta Prævia and of Post Partum Hamorrhage.* By THOMAS UNDERHILL, M.D.—The author dissented from the universally expressed opinion that during syncope from "unavoidable" hæmorrhage no operative procedures should be undertaken, but considered that condition rather favourable than otherwise for podalic version. He was also of opinion that, in cases of *post partum* hæmorrhage, should syncope supervene, it was more judicious to allow that condition to continue for a reasonable time than to use rash and hasty attempts to arouse the patient. The arguments were supported by cases.

*The Value of Arsenic in Menorrhagia and Leucorrhœa.* By J. H. AVELING, M.D.—The author believed that this remedy, although its efficacy in some uterine affections was pointed out by Dr. H. Hunt in 1838, had not received sufficient attention from gynecologists. Dr. Aveling had been administering it for twelve years in cases of menorrhagia with marked success. Besides the improvement which it effected upon nutrition, respiration, and secretion, he believed it to possess a powerful decongestive action upon all mucous membranes. In all disorders of the uterus having a hyperæmic origin, he confidently recommended the use of arsenic. He administered small doses either in solution or granules, increasing them from time to time, and continuing them for weeks or months, as the necessities of the case might require.

#### SECTION D.—PUBLIC MEDICINE.

THE PRESIDENT (Dr. A. P. STEWART), in taking the chair, delivered an address, which is published at page 233.

Dr. SIBSON and Dr. ROW, on behalf of the Section, thanked Dr. Stewart for his admirable address, and expressed a hope that he would kindly allow it to be published, and that it would receive special prominence in the JOURNAL.

*The Climate of Sidmouth, with the results of Meteorological Observations; 1865-70.* By J. INGLEBY MACKENZIE, M.B.—The object of this paper was to prove, from meteorological data, the great equality of the climate of Sidmouth—the small quantity of its rainfall in comparison with other Devonshire watering-places. Its winter temperature was higher than that of Greenwich by some four degrees, whilst in summer it was much below. There were but few, if any, days in the year on which an invalid could not take out-door exercise, the soil drying very rapidly. Sidmouth was a residence for consumptive invalids at the beginning of the present century, when many of the present fashionable health resorts were fishing villages. Its proximity to London, being the nearest Devonshire watering-place, combined with its equality of temperature and other advantages, rendered it a most desirable winter residence.

*The Meteorology of Plymouth for the last Six Years.* By J. MERRIFIELD, Ph.D.—This paper contained deductions from observations taken by the writer over a period of seven years. He pointed out the various causes of error in the circumstances of the recording instruments, the circumstances of soil, etc. He made the mean temperature of Plymouth to be 52.31, within a hundredth of the result obtained by

Sir William Snow Harris over ten years. The hottest months in the year were June, July, and August, 61 degrees, 64.5, and 62.3 respectively. The coldest were January and March, the mean of the former being 42.2, and that of the latter 43.4. The highest temperature registered was in June 1866—93 degrees—which he thought must have been caused to some extent by reflected heat. The lowest was 14 degrees, in December 1869. The lowest relative humidity was in June, the highest in November. He was aware that the existence of the Gulf Stream had been questioned by many, but by the kindness of the local secretary (Dr. Littleton), he was enabled to exhibit some articles which it had washed upon the shores of Cornwall. The greatest range of the thermometer was in June and July; the least was in the winter months. In April 1865, he registered a variation of 44 degrees, and often he had had 30. The lowest was in September last—2 degrees only. The prevalent winds had a westerly tendency. The average barometrical pressure was 29.953. The mean annual rainfall of Plymouth was 38.95, the most rainy months being January, September, and December. The heaviest shower he had ever recorded was on Saturday week last, when in half an hour three-quarters of an inch fell. They went many days in the year without a sight of the sun, and there were few free from cloud. Concerning ozone he had made no observations; though no doubt it was plentiful. Plymouth appeared to enjoy an immunity from electrical storms.

Dr. WESTALL hoped that such papers were preserved. A collection referring to the chief towns and districts in the kingdom would be exceedingly valuable.—Mr. LITTLE was of opinion that the rainfall should always be registered by gauges placed in similar positions. In London they were dependent for rainfall observations upon the Observatory at Greenwich, and he did not know how it was calculated there. Before he came to Plymouth he was told that it rained every day; but he concluded he had been misinformed, as he had not seen any rain for four days.—Dr. WESTALL referred to the fact that Mr. Symons had done all that he could do to secure an uniform system of observation. It was impossible to compare rainfall observations where the gauges were not similarly placed. He hoped it would be possible to adopt the suggestion of Dr. Mackenzie for the formation of a dictionary of climate. Great errors were made upon the subject in popular works. A suggestion had been made two years ago for the publication of a full series of meteorological observations in the BRITISH MEDICAL JOURNAL, but they were dropped after many gentlemen had gone to considerable expense in providing themselves with implements and facilities for observation.—The PRESIDENT (Dr. A. P. STEWART) explained that the omission of the meteorological tables had arisen in great part from the great cost incurred in their composition.—Dr. ROW thought that in making meteorological comparisons, sufficient allowance was seldom made for tidal influence, which was very important. The temperature of the water was much more constant than that of the air; and in a locality like that in which they assembled, it was impossible but that the cooling of large tidal areas twice a day with large sheets of water must have an influence upon the atmosphere. This influence would naturally be most felt in the winter months, when the temperature of the water was considerably higher than that of the air. It was to this influence that he attributed the fact that there were spots in that neighbourhood in which snow would not lie.—Dr. NANKIVELL directed attention to the difference between the night and day temperatures as an important element in the consideration of questions of climate. At Torquay that difference was very considerable.—Dr. MACKENZIE, in reply to Dr. Atkins, said he had known cases of typhoid fever at Sidmouth, but they were of the sporadic, not the epidemic kind. The population of Sidmouth was 3,500, and had slightly increased during the last twenty years. The drainage had been continued to below low water-mark. He attributed the health of the place to the influence of the constant current of air through the valley.—The PRESIDENT inquired whether small-pox was generally prevalent in the district, and would like to have some information as to the present state of Devon in regard to small-pox inoculation. His reason for asking was that eighteen years ago a pupil came up to the Middlesex Hospital from Sidmouth, and was attacked with confluent small-pox, which he then ascertained exuberantly prevailed in an epidemic form in the neighbourhood. He learnt also that small-pox inoculation was then practised extensively there. He thought that Dr. Mackenzie was rather too sweeping in his statements upon the sending of consumptive patients out of the country. Dr. Hermann Weber had sent many to a very keen air with advantage. He had known the climate of the Engadine in Switzerland to have a very beneficial effect; and patients whom he had sent to the keen bracing air of Northumberland had likewise improved thereby. There were towns with a larger population than Sidmouth in which the death-rate was as low as 14.—Dr. MACKENZIE believed that during the late epidemic of small-pox there had not been a case in Sidmouth; nor

was he aware of the existence of the practice of inoculation. He had heard of its being done, and of an old doctor who, when asked to perform it, would refuse, but, if the applicant persisted, would lend his lancet.

*The Difficulties and Trials of a Health Officer.* By DAVID DAVIES, Esq.—The difficulties were enumerated as they had arisen in the author's experience at Bristol. The first was the difficulty of getting early information of the occurrence of epidemic disease, which at present could only be obtained by the courtesy of the general medical practitioners; or by a system of espionage, which was not satisfactory, though it worked well at Bristol. The second difficulty was the confused state of the sanitary laws. Local Boards might—not must—build hospitals for infectious diseases; and when they were built it was by no means clear who the occupants should be. Great had been the evils of the permissive clauses of sanitary legislation. The third was the separation between the registration of deaths and the sanitary authorities, the latter being unable to get the information without paying for it. He did not blame the registrars, but the system was wrong. The fourth point was the division of nuisance authorities and the want of a central power. The fifth was the non-adoption by the medical profession of an uniform nosology. Hence the returns of deaths would puzzle wiser heads than his. The nomenclature of fever was most uncertain, and some called everything fever that ended with febrile symptoms and coma. Sixthly, he placed the importance attributed by the public to the mere figures of the Registrar-General, which of themselves meant very little. Thus the death-rate of towns was swelled by people being sent from the country to die. The public would have their say, and newspaper editors wrote articles which, as a rule, were wide of the mark. No one appreciated more highly the intellect brought to bear by the Registrar-General upon the figures in his possession than himself; but, if that official knew all the details, many places reputed healthy would sink to the lowest depth, while others reputed unhealthy would rise. Seventhly, came the death of many infants under one year old, which was one of the saddest points of all. This arose largely from causes not in the control of a health officer, and rather moral than physical. Many parents were such who never ought to be, and neglect was a great cause of the infantile mortality they deplored. Here, *inter alia*, Mr. Davies said that the system of giving advice gratis, or half gratis, was one of the greatest evils of large towns. If members of the profession undertook a case they should undertake it thoroughly, or not at all.

Mr. LITTLE had been exceedingly pleased with the observations of Mr. Davies, which had been very much to the point. In London, where they registered lodging-houses under the Sanitary Act, they made it compulsory upon their keepers to give immediate information of the occurrence of diseases. If they did not, a penalty was inflicted. But that did not apply to such houses as the members of the section occupied. They might have a member of their families ill with small-pox—and that disease was just as likely to be injurious to the community in their houses as in the houses of the most poor—but in that case there existed no means by which the knowledge of the fact could be definitely ascertained. In fact, as he had stated before the Earl of Ripon, there was one law for the rich and another for the poor. It ought to be compulsory upon the medical attendants of private families to give information of the occurrence of such diseases wherever they might be, not for the purpose of the medical officer interfering with the case, but simply that the medical officer might suggest the means whereby the disease might be prevented from extending. In order to do that without giving umbrage to his medical brethren, the medical officer of health ought not to be a private practitioner. He could not speak too strongly upon that subject. In London these districts were not sufficiently large to occupy an officer of health for the whole of his time. There were forty in the metropolis, whereas, if each gave his whole time to it, ten would be enough. It ought to be made worth the while of persons to do it. There ought also to be an uniform system of action. One district might have an energetic officer who did his duty; but if the adjoining district was neglected the result must be that both would suffer. The permissive system of legislation was really most absurd. If laws were good they should be compulsory. The great object of Local Boards was to save expense; and they would not spend any money whilst they could help it. In this way the suggestions of medical officers, because they would cost money, were not attended to. He did not think the permissive law was likely to be continued. At any rate, the medical officer of health should have it in his power to say that they should be made compulsory. As to hospitals, they had some in London recently erected for the purpose of receiving paupers, but they needed others in which persons, such as servants suffering from infectious diseases, might be received upon payment. He hoped before long to see a proper registration of sickness in force; and with regard to uniformity of nosology, he held that it was a matter which rested with medical men

themselves. The subject of phthisis had not been alluded to. He held it to be of the utmost importance in connection with that disease that full and stringent provisions should be devised for securing the proper ventilation of the lower class of dwellings. This, of course, was a matter that especially affected large towns; where they often found houses built back to back, and otherwise on the score of ventilation structurally unfit for habitation.—Mr. L. ARMSTRONG had declined to be health-officer at South Shields entirely because, if he had done his duty, he should have lost some of his best patients. The recent epidemic of small-pox in that town afforded a forcible proof of the necessity of enlarged sanitary powers. They could trace it to three centres, each originating with a sailor. One sailor was removed to the workhouse, where two women and some children took the disease. However, it was stamped out there. The next case was taken to a low lodging-house, and thence it rapidly spread. A third case was refused admission at the Newcastle Infirmary, and was actually taken through the country by express train to London. There had been 3,500 cases of small-pox and 300 deaths in the town, all of which might have been prevented if the simplest sanitary precautions had been taken.—Mr. G. W. HASTINGS directed attention to the question of the area of health-districts, and to the allied subject of the way in which streams of water and water-sheds should be dealt with. In the recent proposals that had been placed before Parliament, they found Sir C. Adderley suggesting that the union should be taken as the unit area. This was bad enough, but Mr. Goschen's Bill was far worse, for it proposed the parish. His idea was that the county should be the basis of the health-district, and that border streams should be dealt with by joint boards appointed by the sanitary authority of each bordering county.—Dr. NANKIVELL, as Chairman of a Sanitary Board of Health, quite agreed with Mr. Liddle. In ordinary cases common lodging-houses were only inspected as such, and in all other respects were not noticed at all. The dealing with phthisis was likewise a very important matter. There was no doubt that health officers should be independent of private practice, and also to a certain degree of Boards of Health. He did not think things would ever be what they should be until there was some central board to make sanitary work and precautions compulsory. If such an authority were constituted and medical officers of health could not be dismissed without its sanction, they would be placed in a much better position than at present; and the result would be speedily seen.—The PRESIDENT pointed out that some towns, Manchester and Oldham being examples, had made, or were making, good hospital provision.—Mr. BENSON BAKER stated that in Marylebone there were two hospitals, one for the treatment of small-pox patients, and the other for convalescents, provision being made for those persons who were not considered paupers.—Mr. DAVIES, in reply, said that no case of typhus or small-pox could escape him four days in Bristol; but that he obtained that result by espionage. He could extinguish zymotic diseases in the lanes and alleys; but he had no such power in the dwellings of the artisans, and if the contagion reached Clifton it spread like wildfire. He also felt the difficulty arising from the existence in immediate contiguity to the city, of districts in which he had no power where typhoid fever was always to be found. Typhus in Bristol could always be traced to one of three centres—London, Glasgow, or Ireland. He again enforced the opinion that a closer attention to nosology was needed; and endorsed what had been said with regard to ventilation. He was in private practice, and had lost a good many patients since he had become a health-officer—chiefly clergymen and old ladies; but he had gained others, and he liked the work. He had a disinfecting apparatus which could be got up to 300 degrees, and which was used at 250 and found to answer admirably.

**Poor-Law Medical Service.** By BENSON BAKER, M.R.C.S.—The author stated that the problem how not to prevent pauperism had been too well demonstrated under the present administration. Division of authority and opposed personal influence had contributed in no small degree to the evil. The rapid growth of pauperism was an evidence of unsoundness in the law, and defective administration. The present system—if system it could be called—had resulted in the creation of an army of paupers exceeding a million, and costing £7,673,000 annually, the greater part of which burden fell upon those who were least able to bear it. Sickness was the great factor of pauperism, a fact which had never received the attention that it really demanded. Economy was the order of the day; the question should be therefore regarded from an economical point of view. Economy meant really this—to prevent the curable from becoming incurable, and to restrict the occurrence of preventable disease. Ireland in this respect set an extraordinary example to England and Scotland. The deaths were in England one in 43, in Scotland one in 44, and in Ireland one in 60; whilst the deaths from preventable diseases were in England one in 190, in Scotland one in 194, and in Ireland one in 308. In England the amount of relief per

head was 6s. 11d.; in Scotland, 5s. 7½d.; in Ireland, only 2s. 11½d. The position of the Poor-law medical service might be brought in England to the position which it occupied in Ireland, by the whole profession rising in one mass and insisting upon one central authority. The change had been made in Ireland in consequence of a great national calamity. Were they to wait until England passed under a similar experience? In the metropolis, during one of the most severe epidemics of small-pox, by the Privy Council's orders the Poor-law medical officers were dismissed from their positions of vaccinators, and such parishes as that of St. Pancras, with its 250,000 population, handed over to one man. He had been placed in the position of having to attend a woman suffering from small-pox, and being forbidden by the law to vaccinate her infant child. Pauperism dependent upon sickness could not be eliminated by a starved Poor-law medical system. If they adopted the Irish system they would not at all increase the present rates; but would, on the contrary, obtain a gradual decrease of relief. Nothing could be more fatal to the health of the population, or the pockets of the ratepayers, than the aggregations of large masses of sick or of poor. Poor-law surgeons should be appointed alike and paid entirely out of the Consolidated Fund. They should have superannuations; and there should be promotions in the ranks. Dispensaries and dispensers' drugs should be paid for out of the common fund.

**Poor-Law Medical Relief.** By D. T. T. MAUNSELL, M.D.—Dr. Maunsell gave an elaborate account of the various laws that had been passed since an early period in English history on the subject of Poor-law medical relief. He showed that Poor-law legislation had ever been forced on by the pressure of disease, and that recurring sickness was one of the principal factors of pauperism. Indoor relief in the various workhouses was necessary for certain classes, as the old, infirm, widows and orphans, etc., and for those temporarily out of employment owing to the stagnation in some of the multifarious occupations existing in this country; but it was in out-door relief that there was such opportunities for extravagance, or at least that it required the greatest caution in its administration. Out-door relief might be divided into Poor-law medical relief as in the Irish dispensary system, and into other out-door relief not connected with sickness: the former could hardly be abused; the latter might readily run into the supplementisation of wages, of which he gave various instances. This division of out-door relief did not exist in England, at least on any large scale, and the consequence was that whilst in England and Wales the expenditure per head was for in-door relief £8:10, for out-door relief £4:5; in Ireland it was for in-door relief but £3:10, for out-door relief £1; and for Poor-law medical relief 2s. 6d. per head of the recipients. The poor-rate in England and Wales was 6s. 11½d, in Scotland 5s. 7½d, and in Ireland 2s. 11½d per head of the population.

Dr. JOSEPH ROGERS said that, during his short stay at Plymouth, he had collected a few facts which he wished to lay before the members. He had seen in the medical press that the Plymouth guardians had been recasting their medical service. He considered that the way in which the guardians had done this was most improper, and that what had been done would prove most disastrous to the ratepayers. During the last few months, they had removed one of the medical officers, in order to cut down the expenditure. He submitted the following statement, which he had carefully prepared.

	Population.	Acres.	Salaries of medical officers.	Gross Relief.
Plymouth.	62,599	1,635	£500	£24,246
Plympton St. Mary	20,502	74,321	£385	£8,845
Totals	83,101	75,953	£885	£33,091

The expense of drugs was not defrayed by the guardians. This was under the system of limited Poor-law medical relief; and he would contrast it with the Irish system, which was based upon a thorough medical relief. The figures for two Irish towns were:

	Population.	Area.	Cost of drugs.	Salaries of medical officers.	Gross relief.
Limerick	90,756	177,951	£621 12 2	£1,430	£20,275
Waterford	60,000	125,719	£364 17	£900	£12,388

The total expenditure in Ireland included expenses under Registration Acts, Vaccination, Sanitary Acts, and Burial Grounds. All those charges were excluded from the total relief to the poor of England and Wales. The medical relief in Plymouth bore the relation of 1.48th of the gross expenditure; in Limerick and Waterford, of 1.10th of the gross expenditure. The average for all England was, that medical relief was 1.27th of the gross expenditure; in Ireland, it amounted to 1.7th. The salaries of the medical officers of Plympton St. Mary amounted to a few pounds more than the whole cost of drugs in Waterford. In addition to the £900 for salaries, Waterford had expended over £300 in drugs, which made a total expenditure of £1,200. But,

though they had paid this, the gross expenditure for Poor-law relief in Waterford was only one-half as much as that of Plymouth. It might be said that he had only taken one town; but he would call attention to Plympton St. Mary. If they united the population of these towns, they would find a total of 83,000. The population of the latter was only one-third that of the former, and yet the expenditure was £385. The total amount of relief was over £30,000. Let them compare that with Limerick, which paid £621 for drugs, and the number of inhabitants over 90,000, and expenditure just over £2,000. Waterford paid £364 for drugs, with a population of over 60,000; and the total amount of relief was just one-half that of Plymouth. Thus it must be seen that an efficient medical relief had in a most remarkable manner diminished the burdens of poor-rates generally on the Irish people. He particularly desired to call attention to the appointment of a Committee, because he was going to ask the Association to reappoint the Poor-law Medical Relief Committee which was appointed last year, and that that Committee should sit in judgment against the measure which now governed them. A new measure was to be introduced next session, which would be of great benefit to the community at large. He thought the guardians of Plymouth must have acted as they did through ignorance; and they must see it was a great mistake to cut down the Poor-law medical relief; and he trusted it would go forth, and that the guardians would cease for the future to trifle with the lives of the people. He concluded by moving the reappointment of the Committee to which he referred, and a vote of thanks to Mr. Benson Baker for his paper.—Dr. ATKINS seconded the motion.—Mr. BALKWILL supported the motion, and said he did so most cordially; for, being a druggist in the town, he was aware of the startling fact that the cost of the drugs for the Plymouth Dispensary, with a lesser number of patients than were under the Poor-law of the district, cost far more than the Plymouth guardians paid for their service complete, salaries and drugs included. As a visitor of the sick during the late epidemic of small-pox, he had become aware of the fact that the comforts ordered by the medical officers were not supplied until too late. These comforts were sometimes not supplied until a week after they were ordered, and then not unfrequently they were of no use. He had himself seen much suffering in consequence of this. When small-pox last broke out in this town, he visited the patients. There were three deaths out of eight cases; and in the house of one of these poor people there was not any bread, no coals, and not one inch of candle for the night.—Mr. HECKSTALL SMITH thought that, if the facts just mentioned were properly stated to the authorities, it would be impossible for the Board of Guardians of Plymouth or of any other place to keep the poor from their proper supply of necessities, or to stand up in support of such an administration.—Dr. ROW thought that the question should not be discussed in reference to any one locality; and he was of opinion that legislation was required to alter the present system in England.—Mr. HARPER drew attention to the heavy work entailed upon the medical officers of the towns, and said that, though the work was overwhelming, the guardians had decided to reduce the medical staff attendant on the poor.—Dr. SLEMAN said the contract between a medical man and the guardians should be founded upon commercial principles. For his own part, he considered that every contract should be entered into on the just one of paying.—Mr. GEORGE HASTINGS said the facts which had been elicited in the papers and in these discussions had shown that our Poor-law system in England was nothing but a disgrace to the country. Medical men spent a vast amount of time in educating themselves to attain the ability and power of giving the most important functions to the human race; and to ask them to spend the best years of their lives in the worst drudgery and the worst pay offered to any class was a degradation of the civil service of the nation. He believed that the Irish system was infinitely better than the English; and its institution in this country would, he thought, lead to a great diminution in general poor-relief. He did not agree with the remark in Mr. Benson Baker's paper regarding the employment of Poor-law medical officers as health officers; and he should not like to see the Poor-law medical officers made primarily responsible for the duties of health-officers.

[To be continued.]

#### COMMITTEE OF COUNCIL.

THE following ten gentlemen were, at the meeting of the General Council of the Association on August 9th, elected members of the Committee of Council for the ensuing year: M. H. Clayton, Esq., Birmingham; J. Milner Forbergli, M.D., Leeds; Christopher Heath, Esq., London; T. Heskett Smith, Esq., St. Mary Cray; G. Southam, Esq., Manchester; A. B. Steele, L.R.C.P.L., Liverpool; T. Underhill, M.D., Great Bridge; A. T. H. Waters, M.D., Liverpool; C. G. Wheelhouse, Esq., Leeds; M. A. E. Wilkinson, M.D., Manchester.

#### PRESIDENT'S SOIRÉE.

ON the evening of Wednesday, August 9th, the President gave a *soirée* at the Royal Hotel. It was largely attended both by members of the Association and by visitors, among whom were many ladies. Upwards of five hundred guests were present. The members of the Plymouth Vocal Association sang a collection of madrigals and songs during the evening in excellent style.

#### TEMPERANCE BREAKFAST.

A large number of gentlemen connected with the Association accepted the invitation of the executive of the National Temperance League, conveyed through its President, Mr. S. Bowly, and Mr. Rea, its Secretary, to breakfast at the Royal Hotel, Plymouth, on August 10. Mr. Bowly occupied the chair, supported on his right by the President of the Association, Mr. Whipple.

The CHAIRMAN briefly introduced the question of temperance, and invited the expression of opinion on the part of the medical gentlemen present upon the use of spirituous and fermented liquors and their employment in cases of disease. He became a teetotaler thirty-five years ago in spite of the advice of his medical man, and he had never had any occasion to regret it. He felt that the importance of the influence which could be exercised by a body of gentlemen so highly educated, influential, and intelligent as the members of the medical profession was not to be overrated; and in behalf of the National Temperance League, which worked by means of moral suasion, he desired that they would give their fair and candid consideration to the subject, regarding it both in its moral and scientific aspects.

The PRESIDENT of the Association (Mr. WHIPPLE) said he was there to give an opinion upon the abuse of intoxicating liquors. Their use as medicine under proper medical direction and under certain circumstances he regarded as absolutely necessary. When also the powers were much exhausted by overwork and the like, he believed that a moderate use of stimulants was desirable and requisite. When a plant was drooping they stimulated it by water. Water was not a sufficient stimulant for the human body; but small quantities of alcoholic liquor would suffice to produce the effect desired. He was not himself a total abstainer, nor was he an excessive drinker; and whilst he found the benefit himself at times of small quantities of stimulants, he must state that he had derived an equal advantage from the use of tea. That beverage had a wonderfully invigorating effect, and he attributed its advantageous influence upon himself to the fact of his being a moderate drinker. In medical practice it would be impossible to get on without the use of alcoholic drinks. There were particular cases, such as fever, for example, in which they were absolutely necessary. As to what their Chairman said about his giving up such liquors in spite of the advice of his medical man, all he (Mr. Whipple) could say was that one of the two must have been wrong, and judging from the appearance of Mr. Bowly, he was of opinion that it must have been the medical man. Mr. Whipple went on strongly to denounce the practice of morning drinking, and the drinking habits of many of the class of commercial travellers. They said they could not do business without it. That he did not believe, although he knew that champagne was sometimes furnished to unwilling customers to induce them to buy. Another thing that was very much to be deplored was the extent to which youths and young men were to be seen late at night knocking about public-houses, with pipes in their mouths, and beer in their heads. So far as the higher classes were concerned, he was glad, from his own experience, to be able to say that the custom of excessive drinking was by no means so prevalent among them as it had been. He thought they should use all their energies to cause this improvement to permeate the other classes of society.

Dr. JONES (Ross) said that in his own locality there was much cider made, and the labourers, who had very little else but bread and cheese for dinner, were compelled by the nature of their diet to take some stimulants.

Mr. ANDERSON advocated moderation. He believed those who took the least spirit enjoyed the greatest health.

The CHAIRMAN remarked that some medical men doubted the propriety of the use of spirits in cases of fever, etc., and advocated instead the exhibition of nourishing food. Would some of the gentlemen present favour the meeting with their views upon this point?

Mr. MAUDE (Bradford) believed that, whatever might be the decrease of the amount of drinking amongst the males of the higher classes, there had been a very great and sad increase in the amount of drink consumed by the ladies—the young as well as the old. This, he thought, called for the greatest care and consideration upon the part of medical practitioners. He did not believe that they could dispense

with alcoholic drinks altogether in medicine, but still he believed that they were prescribed much more frequently than was necessary.

Mr. HUTCHINSON called attention to the experience gathered in the London hospitals in connection with the administration of stimulants, and stated that from records kept in the hospital with which he was connected, it was found that the practice of those who gave the largest quantities to their patients was not more successful than the practice of those who exhibited it in smaller amounts. He did not see how they were to do without stimulants in such diseases as erysipelas and pyæmia.

Dr. RADCLYFFE HALL (Torquay) said his experience was that the milk treatment in cases of fever failed, but that the milk treatment combined with the administration of very small doses of stimulants produced the best results. He contended that medical men were not to be held responsible for not being always able to square their practice with theory. They often had to deal with patients who were in the habit of taking too much; and the way to deal with such was not to attempt to turn them out of their groove abruptly, which would not act, but to turn them into another—to prescribe, for example, the moderate use of light claret instead of stronger drinks.

Mr. SQUARE utterly repudiated this idea. For persons who were in the habit of taking too much there was no safety but in abstinence. Medical men should set the example of self-denial, and if so, an amount of good would be effected far beyond that which they at present saw. Medical men were moral and religious men, and they should neglect no means whereby they might make their influence for good felt, if only upon one patient.

The proceedings then concluded.

#### EXCURSION TO THE EDDYSTONE.

About eighty members of the Association had a delightful excursion to the Eddystone on the 10th. The Government steamer *Bann* was placed at the service of the visitors, who much enjoyed the trip. The steamer left Millbay shortly before two o'clock, and returned about half-past five o'clock, having made the journey of thirty miles, after allowing for fully half an hour's detention off the rock, within three hours. As the weather was fine the excursion passed off most delightfully, and was altogether a most charming outing. On arriving off the rock two boats were launched, and about twenty gentlemen availed themselves of the opportunity to visit the lighthouse. They were received most courteously by the three denizens of this illuminated home in the Channel, and conducted over the curious building. With the exception of these gentlemen, only eight visitors had landed upon the rock since May last.

#### VISITS TO WEMBURY AND ST. GERMANS.

At the joint invitation of Mr. V. P. Calmady and Mr. J. D. Lewis, M.P., about seventy or eighty members of the Association visited the Yealm on the 11th, being conveyed from Millbay in the steam tender *Bann*, kindly lent by the Port Admiral, Sir H. J. Codrington, K.C.B. The party landed near Wembury Church at a very convenient landing place, and were conducted by Mr. Calmady to a wooded valley close by, where an excellent luncheon was provided. The healths of Mr. Calmady, who presided, and of Mr. Lewis were heartily drunk. After the luncheon the party divided, one portion visiting Langdon Hall, whilst another proceeded to a hill close by, where extensive views were obtained of the river so far as Kitley, the seat of Mr. B. J. P. Bastard, of Wembury House, of Mr. Lewis's property, etc. Visitors were enthusiastic in praising the delightful scenery of the neighbourhood generally, and its adaptability for a watering place, for which Nature had afforded every facility. The southern aspect, the gently sloping beach, the sheltered situation shut in by woody hills, and the abundance of pure water, were highly praised. One drawback is the comparative difficulty of access, but it is understood that the landowners are ready and willing to do all in their power to remedy this defect.—Another party of excursionists left North Corner about midday and proceeded up the river Lynher as far as St. Germans, where they were most hospitably entertained at luncheon by Mr. Kerswill.

#### EXCURSION UP THE RIVER TAMAR.

The proceedings in connection with the visit of the Association to Plymouth terminated on Saturday, August 12th, with trips to Torquay, Dartmoor, and up the Tamar. Through the courtesy of the Earl of Mount Edgcumbe, Cothele Hall, the residence of the Dowager Countess, was placed at the disposal of the river excursionists, and a well-spread luncheon was there provided for them by Mr. Coffin, of George Street, Plymouth. The party, which included a large number of ladies, left North Corner at 1 P.M., and, after landing the provisions at Cothele, steamed up to the Morwell Rocks, and then returned to Cothele. Mr. Whipple, who presided at the luncheon, proposed the

healths of the Earl and Countess of Mount Edgcumbe. He observed that the noble earl had worthily followed in the footsteps of his father in hospitality and courtesy.—The toast was drunk with three ringing cheers.—Mr. Heckstall Smith proposed the health of the President of the British Medical Association, which was drunk with similar honours.—Mr. Watkin Williams, the Secretary of the Association, gave the Local Secretaries—Drs. Littleton and Row—observing that without such coadjutors it would have been difficult to carry out the admirable arrangements which had been made. In his experience he had known nothing so remarkable in connection with the Association as this, what he might term the climax of their visit. There had been plenty to admire in Plymouth and its lovely scenery, but they had had shewn them nothing to be compared with the sight he saw before him, and he desired to express his gratitude to the gentlemen who had been kind enough to bring them there.—Drs. Littleton and Row having replied, Dr. Bryan, of Northampton, proposed the ladies, which was responded to by Mr. Nicholson.

#### EXCURSION INTO CORNWALL.

By the kindness of Mr. Henwood, the President of the Royal Institution of Cornwall, and of Dr. Barham, one of the Vice-Presidents, the members of the British Medical Association were invited to join in the annual excursion of this institution, which took place on August 14th and 15th, and included the principal objects of antiquarian, geological, mining, and picturesque interest in the district west of Penzance. On Monday, August 14th, a large party were splendidly entertained at a champagne breakfast by Mr. Congdon, of Marazion, at St. Michael's Mount, and then assembled at the Penzance railway-station, from which place a start was made immediately after the arrival of the train due at Penzance at 10.44 A.M. The Fougou at Trewoofe was the first spot visited; after which the "Pipers," the "Dawns Myin," "Treryn Dinas," and the "Logan Rock" were inspected. Lunch was provided at the Land's End, after which the party proceeded to Bottallack Mine, returning to Penzance for the night. On Tuesday morning, August 15th, the excursionists assembled at the Causeway-Head, Penzance, from which place they started at 9.30 A.M. Lanyon Cromlêh was the first object of interest visited on the route; here the excursion was divided into two parties; one of which proceeded on foot across the common to Polmear, inspecting on the way the Mên-an-tol, the Mên-Scryfa, the Beehive Huts, and fallen Cromlêh at Bosprennis—the other party in the meanwhile visiting Bossulow Huts or Polmear Cove, with its interesting junction of granite and slate. The whole party then proceeded through the wild scenery of Zennor to St. Ives, where the church and other objects of interest were visited; after which they partook of lunch (for which they were indebted to the hospitality of Mr. Henwood) in the grounds of Tregenna Castle, subsequently arriving at St. Ives Road station in time to proceed eastward by the last train. Some forty members of the Association availed themselves of the opportunity of joining in this most interesting and delightful visit, and they will long remember how greatly they are indebted to their hosts for this rare pleasure.

## MEDICO-PARLIAMENTARY.

#### HOUSE OF LORDS.—Friday, August 18th.

VACCINATION ACT (1867) AMENDMENT BILL.—The House went into Committee on this Bill. Lord Redesdale moved the omission of Clause 10, which provided that, after the passing of the Act, no parent, after being fined twice, shall be subject to further fine, in respect of non-compliance with the clauses for compulsory vaccination. The clause had been received with the greatest triumph by the anti-vaccination party, and it destroyed the whole effect of compulsory vaccination.—Viscount Halifax said it would be a great misfortune if this clause were omitted. A Committee of the House of Commons unanimously agreed that it was necessary to insert this clause. The Committee then divided, and the numbers were: for the clause, 7; against, 8; majority against the clause, 1. The Bill then passed through Committee.

#### HOUSE OF COMMONS.—Thursday, August 17th.

FOREIGN DECORATIONS: DR. GORDON AND SURGEON-MAJOR WYATT.—In answer to Mr. Eykyn, Lord Enfield said,—As the services of Dr. Gordon in Paris last winter were performed with the knowledge of, and under the express direction of, the War Office, he would, I apprehend, be permitted to accept and wear any distinction, not being the decoration of a foreign order, if the French Government had asked it for him, but I cannot ascertain that any such application has been made in his behalf. I should be glad to take this opportunity of as-

suring that gentleman, as well as Surgeon-Major Wyatt, who performed such good and humane service during the siege of Paris, that my words last Friday evening had only reference to the volunteer ladies and gentlemen who worked so honourably under the Red Cross and not to them. I had to draw the distinction between the official and non-official character of the work done under the Geneva Convention.

**THE REGENT'S CANAL.**—Mr. Eastwick asked the President of the Board of Works whether he would cause inquiries to be made into the alleged insalubrious state of the Regent's Canal, which at North Gate is covered with green slime, and is even yet worse at Maida Hill, and caused alarm to persons in the neighbourhood in view of the approach of cholera.—Mr. Ayrton replied that, as far as he could ascertain, the condition of the Regent's Canal was not so bad as it had been in previous years. If anything were wrong, the District Officer of Health would be the proper person to take notice of the fact, and should that officer fail in the discharge of his duty, the Home Secretary would be bound to interfere if applied to.

Saturday, August 19th.

**VACCINATION ACT (1867) AMENDMENT BILL.**—On the consideration of the Lords' amendments to this Bill, Mr. Forster said their lordships had struck out an important clause—clause 10—proposed for the mitigation of penalties, which was passed in that House by a majority of 57 to 12. He should have had no hesitation in asking the House to disagree to that amendment if there were sufficient time; but as that might involve the loss of the Bill, which would effect great administrative improvements, they had no choice but to assent to it. It was an important clause, but not an essential one; and with the disease raging in the country it would not be safe to postpone the Bill. The Lords' amendments were then agreed to.

## MEDICAL NEWS.

**THE ARMY MEDICAL SERVICE.**—The following is a list of the gentlemen who competed successfully for the appointments as Assistant-Surgeons in Her Majesty's British Medical Service at the competitive examination held at the London University, on August 9th, 1871.

Order of merit.	Names.	No. of marks.	Order of merit.	Names.	No. of marks.
1.	Cottle, E. W.	2,060	8.	Bridges, W. P.	1,875
2.	Connolly, P. S.	2,055	9.	Rogers, J. G.	1,865
3.	Dwyer, C. E.	2,020	10.	Ash, R. V.	1,825
4.	Blond, R.	1,970	11.	Grant, W. C.	1,782
5.	Fewden, W. A. D.	1,970	12.	Connolly, B. B.	1,720
6.	Edgar, J. D.	1,890	13.	Barrow, H. J. W.	1,665
7.	Drury, R.	1,885	14.	Barrow, F. E.	1,654

## MEDICAL VACANCIES.

The following vacancies are announced:—

**BISHOP STORTFORD UNION, Herts**—Medical Officer for the Sawbridge-ward District.

**BOURNEMOUTH GENERAL DISPENSARY**—Resident Surgeon.

**BRADFORD (Yorkshire) INFIRMARY AND DISPENSARY**—Physician.

**BRISTOL**—Surgeon to the Police.

**BRISTOL ROYAL INFIRMARY**—Surgeon; Assistant-Surgeon; Dresser.

**BURY UNION, Lancashire**—Medical Officer for the Tollington No. 1 District.

**CHESTER GENERAL INFIRMARY**—Visiting Surgeon.

**COVENTRY PROVIDENT DISPENSARY**—Surgeon.

**COVAN COLLIERY, Rathfriland**—Surgeon.

**GOWER UNION**—Medical Officer and Public Vaccinator for the Western District.

**GREAT EASTERN RAILWAY**—Surgeon to the King's Lynn District.

**GREAT EASTERN RAILWAY PROVIDENT SOCIETY**—Surgeon for the East Anglian District.

**GREENWICH UNION**—Medical Officer for the Greenwich Central District.

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton**—Dental Surgeon.

**ILLINGTON**—Medical Officer of Health and Analyst.

**KING'S LYNN UNION, Norfolk**—Medical Officer to the Workhouse and Infirmary.

**KING'S LYNN**—Apothecary, Surgeon and Agent.

**LEXEDEN and WINTERTON UNION, Essex**—Medical Officer for District No. 3.

**NORFOLK and NORWICH HOSPITAL**—House Surgeon.

**OMAGH UNION, co. Tyrone**—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Eastern Division of the Omagh Dispensary District.

**QUEEN'S COLLEGE, Birmingham**—Demonstrator of Anatomy.

**SLIGO UNION**—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Carrigrohane Dispensary District.

**SOUTHAMPTON UNION**—Medical Officer for District No. 2.

**STAFFORDSHIRE LUNATIC ASYLUM, Barnston**—Assistant Medical Officer.

**UNIVERSITY OF DURHAM**—Medical Tutor at the Newcastle-upon-Tyne College of Medicine.

**UNITED SHIPBURY**—Parochial Medical Officer and Public Vaccinator.

**WESTMORELAND LOCK HOSPITAL, Dublin**—Resident Apothecary and Assistant Surgeon.

**YORK UNION**—Medical Officer and Public Vaccinator for District No. 4.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.

**WEDNESDAY** ..... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY** ..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.

**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY** ..... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

A LIVERPOOL correspondent forwards us the following cutting from a local paper.

"*British Medical Reform Association.*—On the 12th of July, the candidates for the diploma of membership were duly examined in the science and practice of eclectic medicine and surgery, at the Liverpool Museum of Anatomy, No 29, Paradise Street, kindly lent for the occasion by the proprietor, Dr. J. T. Woodhead, to whom the examiners and members of the Association tender their sincere thanks.—*Journal of the British Medical Association*, August 1st." He does not state what paper has been imposed upon; but we will ask him to call the attention of the editor of that paper to our statement that the quotation is a fabrication of an impudent and vile character. We have no knowledge of any such institution or association as the Museum and Reform Association described. There is none such in any way connected with the British Medical Association, nor any authorised to grant any medical titles. We recommend the circumstances and the institution to the notice of the police.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, August 19th; The New York Medical Record, August 11th; The Boston Medical and Surgical Journal, August 11th; The Madras Mail, June 10th; The Shield, August 19th; The Philadelphia Medical Times, July 3rd; The Philadelphia Medical Independent, August 5th; The Birmingham Morning News, August 18th; The Hackney and Kingsland Gazette, August 19th; The North Wales Chronicle, August 19th; The Liverpool Mercury, August 18th; The Civil Service Gazette, August 19th; The Hamilton Advertiser, August 19th; The Western Daily Mercury, August 10th and 13th; The Croydon Chronicle and East Surrey Advertiser, August 19th; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. A. P. Stewart, London; Mr. W. D. Husband, York; Dr. Barham, Truro; Mr. Joseph Lister, Edinburgh; Dr. Spencer Thomson, Ashton, Torquay; Mr. E. J. Worth, West Anderton; Mr. J. F. Harding, Southborough; Mr. Thompson, Stapleton; Mr. J. Crocker, Bingley; Dr. J. G. Davey, Northwoods, Bristol; A Member; Mr. G. S. Wall, Scarborough; Mr. W. J. Stuart, London; Messrs. Mayer and Meltzer, London; Dr. Struthers, Aberdeen; Dr. Sturges, London; Mr. W. Stone, Manchester; Mr. Harry Leach, Greenwich; Mr. R. W. Egan, Dublin; Mr. Rea, Belfast; Mrs. Day, Bath; Mr. W. D. Hyde, Hemel Hempstead; Mr. R. M. Mann, Manchester; Mr. David Davies, Bristol; Dr. D. Page, Kirkby Lonsdale; Dr. J. R. Wolfe, Glasgow; Mr. S. M. Bradley, Manchester; Dr. Protheroe Smith, London; Mr. C. Steele, Clifton, Bristol; Dr. Clay, Plymouth; Mr. Christopher Heath, London; M.D. Edin.; Mr. G. Terry, Mells; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Dr. Dyer Duckworth, London; Mr. W. P. Swain, Devonport; Dr. Joseph Rogers, London; Mr. Worth, Plymouth; Mr. Goadby, Plymouth; Dr. Aitken, Edinburgh; Staff-Surgeon Wells; Dr. Steele, London; Dr. Wade, Birmingham; Dr. Simms, London; Dr. Spencer Thomson, Torquay; Mr. Stamford Felsie, London; Medical Officer; Inquirer; Messrs. Marten and Sons, London; Dr. F. Page, Newcastle-upon-Tyne; The Director General of the Army Medical Department; Mr. R. Harrison, Liverpool; Dr. Parsons, Dover; Mr. Fleischmann, Cheltenham; Dr. Corfield, London; Dr. Grieve, London; Dr. Quain, London; Mr. Grantham, Crayford; Dr. Moriarty, Greenwich; etc.

## PRESIDENT'S ADDRESS,

DELIVERED AT THE OPENING OF

## THE SECTION OF MEDICINE,

*At the Annual Meeting of the British Medical Association,  
in Plymouth, August 1871.*By CHARLES BARHAM, M.D. Cantab., Truro.  
President of the Section.

## THE DISEASES OF CORNISH MINERS.

I OCCUPY this chair, gentlemen, with great reluctance. In any case I should have felt painfully my incompetence to its duties; and I should have declined accepting this, as I have declined other similar offices at this meeting, if proposed to me at the time when such appointments are usually made, on the ground of the uncertainty which hangs over the fulfilment of all distant engagements when one has "fallen into the sere and yellow leaf."

*"Vitæ summa brevis spem me vetat inchoare longam."*

But my incompetency is brought home to me with double force by my knowledge and your knowledge that this Section was to have been presided over by Professor Acland, than whom no member of our profession is more highly qualified to fill the post with honour to himself and advantage to the purposes of the Section, whether by position, acquirements, or zeal in our common cause. We may imagine, too, that he would have experienced some special satisfaction in heading your advance in this locality—in his native county, where his name is associated with all that is most worthy of honour in the character of the English gentleman. Some of you have seen the noble statue of his father, Sir Thomas Dyke Acland, at Exeter, a tribute of universal respect. His accomplished sons, emulous of his excellence, have distinguished themselves in the Church, the Senate, and the Schools, by the same elevation of public spirit and equal ability. Had Dr. Acland been here, we should have been inclined to exemplify towards himself the line inscribed beneath the statue of his father:—

*"Præsentī tibi maturos largimur honores."*

That father is gone to his rest within a few days only; and if anything is a source of satisfaction to me in acting, inefficiently as I must act, as the son's substitute here, it is that I may be saving him from public duties which he would willingly avoid. Of the causes of his withdrawal from our Association, I will say nothing, and I know very little; but we shall all deeply regret their effects. One of them is my presidency over this important Section. When the post became vacant, almost at the eleventh hour, I could not, as a member of nearly forty years' standing, give an absolute refusal to the request of the Committee of Council that I would fill it, although I regarded that request as a sort of observance of the fifth commandment—a mark of respect for seniority. I will repay it by due parental consideration for the fastness of the rising generation, and limit my discourse by the twenty-minutes sand-glass, "with a leaning to mercy." Under the circumstances, I am sure you will favour me with an extra measure of the indulgence accorded to those who "have greatness thrust upon them"; and I am further relieved by the reflection that, although I alone am bound to trouble you with an address, the business of the Section will hardly suffer from my defects, as it will be mainly conducted by Vice-Presidents who have your fullest confidence—Dr. Quain and Dr. Smart.

Had he occupied the place destined for him, Dr. Acland would probably have addressed you on the past, or present, or future of medicine, or all together; and he would have done so with his wonted talent, and with the authority with which he is invested as the head of the medical school of our greatest University. Any such attempt would ill befit a remote country doctor. Perhaps I may employ a few minutes of your time less unprofitably by inviting your attention to some topics of medical interest more or less specially belonging to these western parts, and consequently presenting some features of novelty to our distant visitors. It has, indeed, seemed to me that as, when we look into a local museum, we hope to find, not a futile attempt to imitate by shreds and patches a metropolitan collection, but full and characteristic series of specimens representing the peculiarities of the surrounding districts, so this Association, in successively visiting the seats of particular industries or localities marked by distinctive climatic or other physical conditions, may fairly expect that, whatever else may be brought under consideration, the knowledge and experience of the resident members of the profession in regard to matters of special and local character with which they are daily conversant, shall to some extent be utilised

for the benefit or entertainment of those who have left their homes to see or to hear something new. On this principle of the exhibition of "local productions", the Presidents of the Association and of the Sections are annually chosen; and on this principle I will try to present you with a sketch, in very broad outline, of the most marked diseases and causes of death of the Cornish miner; and I will slightly allude to two other local topics; and, in accordance with the dictum of Horace—

*"Segnius irritant animos demissa per aures  
Quàm quæ sunt oculis subjecta fidelibus—"*

I will, as far as I can, place the great facts before your eyes at least graphically, if my words fail in descriptive power. Those facts shall be also illustrated from the mining districts of Durham and Northumberland, where our last meeting was held, and where the condition of the miner is probably the least unfavourable in this country; and from those of Staffordshire, where it is in some respects worse, in some better, than in Cornwall. I may premise that the great masses of evidence on these matters are contained in the Reports of two Royal Commissions. The first, on the "Employment of Children in Mines", was obtained by Lord Ashley, now Earl of Shaftesbury, and, when issued in 1842, startled the country by its revelations about the collieries; abominations, in regard to the work done by women and children, at once stamped out by public indignation. In this inquiry, Cornwall and the mining districts of Devon were entrusted to me. The second Commission was presided over by Lord Kinnaird. The Report was only issued in 1864. The medical evidence on this occasion was much enriched, and derived greatly increased precision, through the direct examination of a large number of miners by Dr. Peacock and Mr. Bankart; and the statistics of the subject were elaborated with his accustomed skill by Dr. Farr. Dr. Taylor, Mr. Angus Smith, Dr. Bernays, and other men of authority, also contributed the aid of accurate science to the estimation of the impurities of the air in which the miner works. Besides these sources of information, unfortunately buried in blue-books, much has been done by private investigation; and particularly I feel bound to mention Mr. Blee, of Truro, as one of the first to work out the proportionate longevity of the mining and non-mining population of the same districts, and as having just now brought down his inquiry to the latest possible date, and furnished me with his main results.

You will, I think, get over the ground most rapidly by first seeing what a Cornish mine is—the miner's place of work. The form of this results from the geological conditions of the metalliferous veins. These have a general direction from east to west for those producing tin and copper—by far the most important—and from north to south for lead. They are more or less inclined from the perpendicular. Here is the great source of the difference between these mines and collieries as places of labour; the latter being excavations of beds of generally horizontal direction. The one is a vertical fissure through the earth's crust, filled with metallic wealth; the other, a deposit of the vegetation of eras long bygone, or, if you please, a concentration of the sunbeams of the early ages of the world, ready to be diffused again for the cheering of our winters with light and heat. In both alike, the raising the material to the surface is a process of money-grubbing, and the expenditure in it of human life and health has been too often but lightly regarded. In a double sense,

*"Effodiuntur opes, irritamenta malorum."*

Governed, then, by the above physical conditions, the Cornish mine consists essentially of horizontal galleries (or levels) run along the course of the vein for its excavation. These levels are opened at intervals, usually of sixty feet, through the depth of the workings, and access is given to them by shafts, either carried down on the course of the veins, or, more commonly, so as to intersect them. A gallery is also usually carried horizontally to the surface, as deep as may be in the mine, for the readier discharge of water. As the mine becomes deeper, separate shafts are made for the machinery, and shorter ones are also carried from level to level. The miner usually removes the vein from below upwards, and the aid of blasting is constantly called for. The air becomes impure from the breathing of the miners, from the burning of the candles, and from the explosion of gunpowder; and no means hitherto employed are adequate to more than a very partial correction of the evil, in those more advanced parts or ends of the workings especially, where the miner is often necessarily employed. The above causes also raise the temperature; but its elevation is still more due to that of the earth itself, which increases with the depth about two degrees in every hundred feet, so that it often reaches to ninety degrees, and in one instance has even reached a hundred and twenty-three degrees. Other mines, or parts of mines, chiefly the shallower, are cold and draughty, and almost all are more or less wet, rendering heat or cold more sensibly felt.

The Cornish miner usually works eight hours in the twenty-four, by day and night in a regular rotation, besides going to and from his place of work in the mine—a heavy addition to his labour, where he has to ascend a thousand feet or more by ladders, the universal mode thirty years ago, but now superseded by machinery in about a dozen of the most important mines.

This is a very imperfect sketch; but it is sufficient to show you that the Cornish miner works without sunlight, in a very impure air, in a thick cloud of smoke, and in a very hot place. His posture is also often constrained, and his labour wearisome; the immediate result being commonly a loss of five or six pounds during his work, and great prostration, with weak and irregular cardiac action at the close of it.

Underground labour is usually commenced at an early age, whilst the frame is still plastic, and when nutrition should be well maintained. Of 464 miners examined by Dr. Peacock, 40 (or 8.6 per cent.) began working underground from seven to nine, 185 (39.8 per cent.) from ten to thirteen, and 115 (24.7 per cent.) from fourteen to fifteen. These ratios for the respective ages are quite as high as those returned to me for a much larger number thirty years ago.

The ill effects of the conditions under which this underground labour is carried on are marked by the general sallowness of the class, especially as contrasted with the healthy ruddiness of the women and children belonging to it; by spareness of frame, as compared with the other workmen around; and by a certain worn and weary look, often giving the appearance of more than the real age. A pretty correct notion of the deteriorated condition of the miner, short of his being quite unequal to underground work, may be derived from the following table, given by Dr. Peacock, which shows the state of 464 boys and men found at work.

TABLE I.—Table showing the State of the Miners found at Work.

Ages.	Number examined.	Healthy.	Pale.	Worn.	Decidedly delicate looking.	Complaining of various symptoms of indisposition*
Under 21 ..	117	42	36	2	32	5
		35.8 p. c.	80=68.3 p. c.		37=31.6 p. c.	
21 to 40 ..	233	112	45	14	45	17
		48.06 p. c.	17.1=73.3 p. c.		62=26.6 p. c.	
41 to 63 ..	114	43	8	3	33	29
		37.7 p. c.	52=45.6 p. c.		62=54.3 p. c.	
	464	197	89	17	110	51
		42.4 p. c.	303=65.3 p. c.		161=34.6 p. c.	

It will be seen that one-third at least of the whole number were distinctly unhealthy.

If I had time for it, there would be no particular advantage in treating on this occasion of the ordinary disorders caused by exposure to wet and cold, or its alternation with excessive heat, which miners are always subject to from time to time. Rheumatic, catarrhal, and inflammatory affections are, of course, frequent; but they can hardly be called peculiar to the class. Dyspepsia is more so; it is often suffered from early in the miner's working life, and doubtless contributes largely to the deterioration of constitutional vigour, from which those diseases to which his death is attributed in the register derive their force, if not their origin. Another disorder, which he calls "slow fever", is distinctly traceable to his occupation, and is interesting in itself; but it is not so extensively prevalent, or so fatal, as to justify my dwelling on it here. The following statement of the results of Dr. Peacock's examination of eighty-three miners disabled by sickness will furnish a fair average of the proportionate prevalence of various forms of disorder in the class.

TABLE II.—Cases of Disease among the Miners examined in July and August, 1867.

	Cases.
Dyspepsia, or organic disease of stomach ..	1

Kidney-disease and dropsy ..	2
Disease of skin ..	2
Effects of injury (not otherwise classed) ..	2
Total ..	83

I will proceed to point out the great facts which stand in high relief on the face of the tables of mortality—the terrible sacrifice of life entailed by underground labour in the Cornish mines; and the one paramount disease, designated "consumption" in those tables, by which that sacrifice is caused. The former sad tale could not be more strikingly told than in the subjoined numerical comparison of the death-rate among miners and non-miners.

TABLE III.—Annual Death-Rate per Cent. (1) of Miners; (2) of Males, exclusive of Miners, in Seven Cornish Districts.

Ages.	In the Five Years 1849-53.			In the Three Years 1860-62.		
	Miners.	Males (exclusive of miners).	Difference in the death-rate of miners and non-miners.	Miners	Males (exclusive of miners).	Difference in the death-rate of miners and non-miners.
15 and upwards.	1.797	1.854	.057	1.938	1.785	.153
15	.890	.712	.178	.944	.750	.194
25	.896	.884	.012	.957	.832	.125
35	1.430	.999	.431	1.512	1.008	.504
45	3.531	1.476	1.875	2.974	1.250	1.724
55	6.317	2.412	3.905	6.321	1.996	4.325
65 to 75	11.123	5.861	5.262	11.051	5.331	5.720

It will be seen that while, up to the age of thirty-five, the difference is not very great, it increases very rapidly afterwards, till, from forty-five to sixty-five, the proportion of deaths among the mining class is nearly threefold that in the other. The following table shows the second great fact—the class of diseases by which the excessive death-rate of the Cornish miners is chiefly produced.

Out of 10,000 deaths (from all causes) of males above fifteen, there were registered as deaths from consumption—

TABLE IV.

	In England.	Of Cornish miners.	Difference.
15	312	247	65 less.
25	354	331	23 "
35	309	549	240 more.
45	263	1,206	943 "
55	186	1,394	1,208 "
65 to 75	85	652	567 "
Total	1,509	4,379	2,970 more.

The disease here designated consumption is not usually connected with tubercle at the ages when the mortality assigned to it is so great. It comprises the chronic forms of pleurisy, bronchitis, pneumonia, asthma, emphysema, and other chest-affections, and is characterised by slow decline, with progressive loss of breathing-power. The various structural changes have not been ascertained so precisely as might be wished, *post mortem* examinations having been rare. The miner will never die of chronic disease in hospital; and the process is abhorrent to the feelings of survivors at home, as well as very inconvenient in the cottage. The following notes of an autopsy performed by Dr. Peacock and Mr. Bankart constitute the only record of the kind presenting any fulness and accuracy of detail with which I am acquainted; and it may be regarded as a fair specimen of the complication of diseased conditions evidenced in a great many cases by symptoms and physical examination, although some of its features are exceptional.

The affection seemed to have originated in bronchitis and pneumonia, leading to collapse or consolidation of the lung; and no tubercle was found in any part of the body. The patient was a man fifty-five years of age, who had been a miner since he was thirteen or fourteen years old. He had been laid by ill for three years, though ailing for a greater length of time. The left lung was found slightly attached to the parietes by old cellular adhesions; it was voluminous, somewhat emphysematous at the edges, of a deep blue or black colour, and sparingly crepitant. The bronchial tubes contained much secretion, of a dark brown colour. The right lung was universally attached to the

parietes by strong fibro-cartilaginous adhesions. One of the ribs was carious; and an abscess had formed in the situation, containing thick yellow pus, which involved the pleura, but not the lung itself. The substance of the lung was of the same colour as the left, and entirely solid, except towards the upper part, where there were several irregularly shaped cavities, which, together with the bronchial tubes, contained a similar brown material to that found in the tubes of the left lung. The bronchial glands were also very large, hard, and of a black colour. In the bronchus of the right lung, the terminal portion of that of the left, and the commencement of the trachea, the mucous membrane was deeply reddened, and studded with small yellowish coloured deposits of lymph. The trachea and larynx were large; but the mucous membrane on the epiglottis and cordæ vocales, though thickened, was free from ulceration.

To obviate all sources of fallacy, we will throw together the deaths attributed to "consumption" and those registered under "other diseases of the lungs", and compare the mortality of the Cornish miner from these causes with that of the other great mining districts and that of all occupations in all England.

Out of 10,000 males who attained the age of fifteen, there were registered as dying of all lung-diseases—

TABLE V.

In England : All occupations.	MINERS IN			
	Cornwall.	Stafford.	Durham.	South Wales.
2,866	5,596	2,655	1,958	3,037

Hence it is clear that underground work does not entail *per se* any excess of mortality from this class of diseases; and that its lamentable excess among the Cornish miners is owing to the special conditions of their labour, of which a summary view has been given. Heart-disease is a less frequent cause of death here than in England generally—much less so than in Durham. There is sufficient evidence that the mining districts of Cornwall are in themselves as healthy as almost any part of England; but the inference drawn in the Report of Lord Kinnaird's Commission, from the small number of deaths, except from lung-disease, that the miners would be peculiarly exempt from other fatal maladies, is hardly safe; a large mortality from any one cause necessarily lessening the number of those subject to perish by other causes.

Although not strictly within my subject, a cursory glance at the comparative frequency of death by accident among Cornish miners will be interesting. It is furnished by the following table.

TABLE VI.—*Death-Rate by Violence, per Cent. of Males aged 15 Years and upwards in five Years, 1849-53.*

Ages.	All England.	MINERS.		
		Cornish.	Stafford.	Durham.
15	.089	.200	.754	.243
25	.098	.211	.768	.223
35	.115	.188	.823	.333
45	.144	.237	.882	.370
55	.160	.148	.680	.375
65 to 75	.183	.209	.684	.290

I can only point to the much larger proportion of these fatal accidents at an early age—the age of carelessness—compared with the total deaths. The loss of life thus caused in Cornish mines, although considerably greater than in the community generally, appears insignificant by the side of that in the Staffordshire collieries, with which those of South Wales nearly correspond.\*

It is satisfactory to me to be able to state, from the data furnished by Lord Kinnaird's Commission, and from the more recent inquiries of Mr. Blee, that there has been some progressive lessening of mortality, both from disease and from accident, in the thirty years since the date of my own report. The former amendment, which is coincident with a like change for the better among the surrounding population, may arise in great measure from freer command of the necessities of life; the latter is a good deal owing to the introduction of substitutes for ladders into many of the larger mines.

I have no time for comment on the great facts I have stated; and my audience can need none. Their application to civic life, where

\* The plans and sections of Cornish mines, and the comparative ratios of mortality from various causes at different ages in the several districts, were very clearly shown by coloured diagrams, which we cannot reproduce.

similar agents of disease and death are at work in mitigated intensity, is transparent.

It was my wish and intention to say something about the prevalent diseases of Plymouth from 1727 to 1752, as they are described by that excellent example of the old physician, Dr. Huxham, who has placed them on record, month by month, together with a minute meteorological register, during the whole of that period. But I must content myself with remarking that the prevalence of intermittent fevers at that time—they have been nearly extinct here during the present century—may be attributed in great part to the former marshiness of a very large tract, now in the centre of the town; an evil influence probably intensified by an unprecedented term of thirteen years in succession, with rainfall much below the average.

I cannot conclude without endeavouring, in the fewest possible words, to point out to you a new weapon against disease and delicacy of the chest, in the climate of the Isles of Scilly. Placed in the midst of a warm sea, frost of any severity is quite unknown, and the summer-heat is never intense.\* The extreme range of the thermometer is from 75 deg. to 28 deg. In short, the climate is by far the most equable in the British Isles. The rainfall is much less than on the mainland. The vegetation is almost tropical; the aloe, said to flower in England once in a century, may be seen blooming every summer, and the mesembryanthemum dazzles everywhere. To reside there is to have the benefit of a sea voyage, in a genial air, without the chance of being drowned.

## CLINICAL MEMORANDA.

### WASP-STINGS.

A FEW days ago, I had a hasty summons to see a lady who was said to be nearly suffocated, having been stung by a wasp in her mouth. I arrived within an hour of the occurrence. Her whole face was very much swollen, and the eyes nearly closed; the neck and the upper part of the chest and the arms were swollen, and dotted over with a red rash. Her breathing was very short and hurried; but she could swallow without much difficulty. The tongue and inside of the mouth were also swollen, so that I could not examine the throat; but I could see the mark of the sting in the centre of the inside of the upper lip. The accident occurred in drinking wine at luncheon; and I was told that the symptoms commenced almost immediately afterwards, and were at their height within half an hour, when she was cold and faint, and the breathing worse than on my arrival. Ammonia and oil had been applied to the sting, and had taken away all the pain; and the treatment now was to constantly foment the face with hot water, the vapour being also inhaled through a sponge over the mouth. This had a marked effect in reducing the swelling of the face; and on leaving it off for a few minutes, it evidently began to increase. I saw my patient again in the evening; all the urgent symptoms had subsided, but there still remained considerable swelling of the face, much of which had not subsided even on the following day. By a strange coincidence, the next day, I was shown a leg very much swollen from the foot to the knee, and quite hard and very hot, from a wasp-sting in the calf of the leg. As such accidents must be common at this season, they must affect some persons more severely than others, or such cases, as I have mentioned, would be more frequently met with.

Mells, Frome, August 19th, 1871.

GEORGE TERRY.

### IRON IN SCARLATINA.

I NOTE in the JOURNAL of August 12th some remarks by Dr. Russell Aldridge on the use of iron in scarlatina; and as I happen to have had not a little experience in that ailment, am glad to be able to confirm his views relative to its treatment. Having repeatedly seen the best results from the use of iron in small-pox, I determined to see its effects in scarlatina; and during the past few years have had reason to place it as a well-proved remedy, particularly in those cases in which the throat-affection was a prominent symptom. I usually employ the perchloride with chlorate of potash and the solution of the acetate of ammonia, to help, with warm baths, in promoting diaphoresis. If deglutition be difficult, and the little patients very averse to being dosed, I generally use a stronger solution of the medicine as an application to the fauces, believing that it does good not only locally, but generally. The too frequent accompaniments of this disease—glandular, ophthalmic, renal, and other mischiefs, have been most certainly modified, or altogether prevented, by a somewhat early administration of quinine.

Bingley, August 17th, 1871.

JAMES CROCKER, M.R.C.S.E.

\* The rainfall at Plymouth from 1727 to 1752, and the climate of Scilly, were shown by coloured diagrams.

## FASHIONS IN MEDICINE.

*The President's Address, delivered at the Annual Meeting of the Metropolitan Counties Branch, July 17th, 1871.*

By J. RUSSELL REYNOLDS, M.D., F.R.S.,

Professor of Medicine in University College, and Physician to University College Hospital.

THERE are "fashions" in medical science as well as in medical practice; and, like fashions in other quarters, they have their uses and abuses,—they effect some good, and they do some harm. The use of fashion in scientific matters is this, that great attention is bestowed upon the object that may be said to be "fashionable," whether that be a method of work, a direction of work, or the employment of some agent which is believed to be capable of effecting certain results; and that this great attention resolves itself, as times goes on, into a sifting process, which enables those who fall in with the popular method, direction, or agency, to separate the useful from the useless, and to "throw away the worse half." The evil of fashion in matters medical is this, that, by the individual, the sifting process is ignored; there is often easy acquiescence in, and unquestioning adoption of, the principle or agent which is felt to be in vogue; and thus either or both may be employed to the exclusion or neglect of means and agencies which we can ill afford to lose. All multitudes, masses, or sets of men have a tendency to run into extremes, and individuals who make up such masses are not free from the influences to which classes are exposed. It is hard work for any one to set himself against, and make way against, the current by which he finds himself surrounded; he too often finds it easy and convenient, and thinks it wise, to fall into the wake of others, and thus add force to the stream by which he and they are carried onwards. The result may be happy or disastrous; but very commonly, without being one or the other in an extreme degree, it is eminently unsatisfactory and disappointing, and the physician or surgeon has to work his way back again almost to the point from which he started, knocking against broken pieces of systems and of thoughts which he might have pressed into his service a few months or years before.

There is, I believe, when any current of thought or work sets in strongly in matters medical, some true reason for its existence; and it would be well if the sifting or critical process were at once adopted, in order to avoid the evils I have sketched; but the leading is sometimes so strong, and the movement that is made by the individual so unconscious, that not until he comes into contact with awkward, unexplained, or unthought of facts, does he recognise the direction in which he is drifting, or appreciate the aids which he has run by in his easier course.

I have been led to make these remarks because I think that, in the present day, we have set undue importance upon certain elements or features of disease, and have disregarded other equally important guides in that which is our real work—the recognition and treatment of the various "ills that flesh is heir to." Is it not true that, for some ten years past, we have practically ignored what our patients can say to us about their feelings, and have based our judgments and therapeutics upon our own direct observation of the phenomena of disease? Is it not the "fashion," I would ask, to direct attention almost exclusively to what has been termed "objective" symptoms, and to pass over as valueless, or nearly valueless, all the statements that patients make, and indeed all that group of symptoms which has been termed "subjective"? To me it appears that such is now and has been the practical tendency of the last ten years, and that our patients and our profession have suffered from that tendency. Permit me, therefore, for a few moments to direct your attention to this question.

The great value of so-called "objective" symptoms is this—first, that there is an *exactness* about them which is both attractive and valuable, and it is possible to weigh some, and to measure others; secondly, that there is a possibility of *recording* them, which is gratifying and useful; and thirdly, that the records we can make of them form the materials for *comparison* between one case and another, and between the different epochs of the same case. No one can set a higher value than I do upon these elements—exactitude, record, and comparison; and I earnestly hope that our profession will never fail in due regard to those essential conditions of its work; but it seems to me that attention to symptoms which can be so measured, weighed, and compared, has often led the mind away from other features of disease which will not submit themselves to our scales, crucibles, or thermometers, but which are among the earliest—often the only—indications of departures from health, and which may truly guide us in our diagnosis, prognosis, and treatment.

The great value of so-called "subjective" symptoms is this, that they tell us of changes, of diseases—in the true sense of the word—in the

suffering man that cannot be either weighed or measured; that they occur often before any other objective phenomenon of disease presents itself; and that they thus, alone and of themselves, constitute for weeks, months, or it may be for years, the whole history of many most important cases.

It may be replied, that the statements of a patient are often valueless; that they show nothing definite, and point to no therapeutic act; that they are often the result of fancy, or of something worse; and that it is wiser to ignore them, and lay hold of the tangible and true. This kind of statement is, I think, open to all the objection which it makes to the reception of such testimony with regard to disease. It is eminently subjective, and so liable to personal misuse. But, further, I would ask are not the phenomena which we can weigh and measure often thoroughly outside the object we have in view—the treatment of a patient? Is not much of the record of cases a mere collation of exact and learned lumber, from which no good has yet come, or is likely to come? And, if we would duly consider the matter, is not a phenomenon of sensation, of thought, or of feeling, of as great importance to the well-being of a man, as is one of secretion, or temperature, or weight? Again, is it not simply because we have not yet been able so to observe, arrange, analyse, and compare these "subjective" symptoms as to give them a definite value, that we have regarded them so lightly? And, lastly, is it not true that such symptoms must have a real pathology—must be but the expression of some morbid changes, for which we may have no name, but which are, in themselves, as definite and important as any others which we have been able to examine more minutely, and express more exactly? In other words, is not the diminished value of subjective symptoms a fault of our profession and of its mode of work, rather than a demerit, or fallaciousness inherent in the facts themselves?

Let me illustrate the value of some subjective symptoms by a few examples from actual practice, and show in what way and to what degree they may be utilised.

Of certain blood-diseases, the earliest indications are often of this neglected class: obscure discomforts of feeling in the region of the epigastrium—a form of dyspepsia, which it is sometimes difficult to place in any category—which baffles treatment directed in accordance with all proper principles, and is sometimes looked upon as "hypochondriacal"—may often be at once relieved by treatment based upon the hypothesis of gout. Sensations referred to the heart, to the chest, to the head, palpitation, vertigo, or the sense of dyspnoea, may be disregarded, although they are urgent enough to hinder work, and make life miserable; and yet, after months or years of fruitless therapeutics, they may yield at once to a well-directed treatment based upon the diagnosis of the particular blood-change. Is it not possible that a careful consideration of subjective symptoms might lead to an early diagnosis, and to a successful application of means for relief, and thus ward off the development of the disease?

Again, some of the earliest indications of such disease as carcinoma of an internal organ are often purely subjective; a sense of weariness, of depression of spirits, of carelessness, or really indisposition, from feeling of inability to attend to affairs, may be the first warnings of a malady which might be postponed, if not averted. Are not patients who have these symptoms sometimes rallied for their fearfulness, and, because nothing can be found, advised to do this or take that which subsequent history proves to have been not only useless, but injurious?

In heart-diseases of the very gravest kind, subjective symptoms have often been the earliest and the only evidence. Some feeling of distress—abrupt, sudden, unexpected, and unprovoked—has given alarm to a patient; but when his physician sees him the distress is past, the sounds are natural, the beats, though feeble, may be regular, and there is nothing to be seen or heard that should not be observed in one who is tired or overdone. "Nothing is the matter" is the common verdict; and the symptoms may go on, disregarded by all but the sufferer himself, until some terrible catastrophe occurs, and the certificate of death is either "angina pectoris," or "fatty disease of the heart." Is it not possible that, in some such cases, an earlier attention to warning symptoms might have done something to arrest the malady? or is it not certain that it might, at least, have prepared the patient or his friends for the solemn issue?

In lung-diseases, it has seemed to me that subjective symptoms are often the earliest indications that something is going wrong. Before there is any definite attack of asthma, there are often feelings—unprovoked and unaccountable—of dyspnoea and distress, which are allowed to be dyspeptic or hysteric, but which might, by careful examination, be separated from one or the other of these categories. So with phthisis, and so with emphysema. Often, before either of these diseases has so far developed itself that physical signs will reveal its presence, there may be symptoms of its existence. In the latter disease, the sense of tightness of chest and shortness of breath, with a little dry hacking,

may exist long before the percussion of the chest reveals undue resonance, or auscultation shows any lengthening of the expiratory murmur. Might we not here do something by early notice of subjective symptoms?

In nervous diseases, the application of the remarks I have made are endless. The early symptoms of ataxy and of general softening of the spinal cord are often such as are subjective only; feelings of weight, or want of equilibrium, or of restlessness, which go for nothing when the patient is under the stimulus of the physician's presence, and can walk firmly, and stand on one leg with his eyes shut; but which, nevertheless, when neglected, creep on until a malady is obviously present which our science may arrest, but can rarely cure.

The early subjective symptoms of brain-disease are too numerous for detail. I will only allude to a few examples, which I am sure you can multiply indefinitely. The "general paralysis of the insane" often passes unnoticed until it is highly marked; and yet at an early period some apparently trifling change in the feelings of the patient, some exaggeration of self-importance, or slight egotism of manner, might have given the alarm, when found in conjunction with certain slight and occasional physical weaknesses which have to be looked for to be found.

The early symptoms of "softening of the brain" are often complained of and disregarded, or set down to dyspepsia or fatigue, simply because they are subjective. A feeling of bewilderment, or of want of mental grasp or grip; an inability to take in new notions; a listlessness or carelessness, with sometimes a sense of well-being, are among the most significant of the signs of cerebral decay. Might we not here often arrest and even postpone indefinitely the progress of disease?

In epilepsy, it often happens that long before the attacks have developed into even the minor seizures of *le petit mal*, the patient has been conscious of some strange and sudden mental condition which he cannot describe, but which is significant enough. Here, and in allied cases, could we not do much by an early recognition of the possible disease? In all these cases I think we could. A scrutinising attention to the minutest departure from health, in mind, or emotion, or sensation, would, I believe, help us greatly in the estimation and prevention of disease; and we must ever remember that in the practice of our noble profession we have to deal with man as a whole, to examine him and to treat him as such; that by neglecting any part of the information which he can give us with regard to his sufferings or his wants, we shut out from ourselves one great source of information which we can ill afford to lose; and that by putting aside that kind of knowledge of his state, which can come to us only through the workings of his own mind, we rob ourselves of those elements for a correct diagnosis, without a due establishment of which all our attempts at treatment must be either empirical or fruitless.

### MODERN MEDICAL DOCTRINES.

*Extract from the President's Address, delivered at the Conjoint Annual Meeting of the East Anglian and Cambridge and Huntingdon Branches, at Norwich, June 30th, 1871.*

By PETER EADE, M.D. Lond., M.R.C.P.,  
Physician to the Norfolk and Norwich Hospital, etc.

[AFTER thanking the members of the Branches for the compliment paid to him in his election as President, and offering them a welcome to Norwich, Dr. Eade gave a brief sketch of the history of the city, referring especially to its honourable position in the pursuit of the sciences and arts, and especially in the annals of medicine. He then proceeded to give a review of the progress of medicine during the year.]

With regard to the year that has passed, I would venture to express the opinion that, since our last anniversary, the science of medicine and its allied branches of knowledge have continued to progress. We may not have had such a valuable boon as chloral provided for us, nor such a great theory propounded as that of the safety-giving influence of carbolic acid after operations; but still I think that those who have perused our JOURNAL and the general medical literature of the country, will agree with me that there has been no check to the steady persevering work of our medical inquirers, and also that in this work various members of the British Medical Association have borne their full share. Even if nothing else had been done, the discovery of the inoculability, not only of portions of the integument, but even of the epithelial scales—of the very dust of our skins—upon the raw surface of another individual, would be almost enough to mark a distinct era in our advancing knowledge. Coming as it does upon the heels of Villemin's discovery of the inoculability of tubercle and other organised matter, there is no doubt it is helping to clear the ground for our thorough understanding of the pathology of pyæmia, of all cellular

and many contagious diseases, and—may I not say?—of phthisis itself. For it is very clear that, if we can see that isolated particles or cell-dust from the skin can live on a fresh surface and there grow and increase, there is no difficulty in believing that similar particles shed from the surface of the pulmonary mucous membrane can be inhaled by a second person, become transplanted on to his mucous membrane, and constitute there the starting point of a fresh and similar disease. I am of course aware that this possibility is by no means demonstrated, and that tuberculous particles differ considerably from ordinary nucleated epithelial scales; also, that there is much negative evidence to be adduced against this view. But when we remember that, whatever their microscopic characters, tuberculous matters have been proved to be capable of reproduction, and also call to mind the many instances which are constantly occurring of untainted individuals nursing the consumptive and themselves quickly becoming victims of the disease, there seems reason at least for believing that this is not unlikely to be shown hereafter as a true fact of this disease, and that the opinion long entertained of the occasional contagiousness of pulmonary phthisis is founded in truth. It is not long since the communicability of typhoid fever and cholera was vehemently contested. We now know (thanks, I believe, mainly to the researches of two eminent members of this Association—Dr. W. Budd, and the late Dr. Snow) that both these diseases are communicable by the reception into the system of particles—possibly mere poisoned epithelium—discharged from the mucous surfaces of diseased individuals.

It is really most lamentable that the true clinical history of such a disease as consumption, which destroys one-sixth or one-seventh of the whole population, and which is open to the observation of every one of us, should still be wrapped in such impenetrable darkness. The discovery of its inoculability into lower animals would seem to be the one ray of possible light which has lately been shed upon it—for the distinction of phthisis into several varieties, and the more accurate recognition of its various pathological forms, has as yet done little for its elucidation, and has not even enabled the best observers to agree as to the interpretation of the best known facts. In illustration of this, and of the consequent need for more work in this direction, hear what a reviewer of Niemeyer's recent *Lectures on Phthisis*, writing in the *Edinburgh Medical Journal* for December last, says. "There is no work," he writes, "on the treatment of phthisis in the English language so advanced in its pathology. It leaves the crude theories of Laennec and his followers far in the rear, and, by showing the essential dependence of tubercle on preceding inflammatory processes, it also shows, etc." Now contrast this with the views expressed by one of the most able and experienced physicians of our own country in the special field of consumptive disease. No longer ago than April last, Dr. Cotton wrote in our own JOURNAL to this effect. "Phthisis is, in my opinion, one of the diseases of organic degeneration, consisting essentially in the development or deposition of a certain lowly organised and variously constituted material, which we call tubercle. In the great majority of consumptive cases, I believe that such deposition is not due to inflammatory action—any inflammation, whether pulmonary, bronchial, or pleuritic, which may accompany it, being of a secondary kind." Dr. Cotton goes on to say that many cases of phthisis do begin with some form of pulmonary inflammation; but his general opinion on the subject I have quoted above in his own words.

Three or four years ago, at the meeting of our Association at Oxford, I read a paper in which I ventured to propound the opinion that a lowered vitality—nervous and anatomical vitality—of the pulmonary tissues was an essential element of the development of tubercular growths; and that, as tubercle itself was a low form of cell or nuclear growth, so it flourished only at best in lung-tissue, whose vital resistance was lowered by abstraction—either directly or reflexly—of nerve-power, so as to render it an appropriate soil for the development of this lower type of growth. All increase of knowledge since this time seems to have rather strengthened this view; and certainly a capability of previously healthy individuals for receiving and permitting the growth of inhaled tubercle-germs upon their pulmonary mucous membranes, when exhausted by nursing and anxiety, would not militate against it. Whether the result be actually induced in this disease, to quote the words of Mr. Paget, in his recent lecture on Dissection-Wounds, "by mere diminution of a normal power of resisting changes," or (as Dr. Carpenter has shown to be much more probable) by the production in the fatigued organs of some material on which morbid poisons may multiply and flourish, seems uncertain; but the tenor of this passage evidently is to show the belief of both these eminent physiologists and pathologists in the power of implantation and growth of living particles on or in lung-tissues, which they could not invade when these were in possession of their normal vitality. Other examples of this effect of lowered innervation in permitting the springing up of a lowered type

of growth are well seen in the hypertrophy of connective tissue, which accompanies the progress of the disease known as Duchenne's paralysis; in the formation of pus in parts where nerves are compressed or interfered with by tumours or injuries; and in the development of cancer elements in lymph exuded after an injury, and so placed beyond the reach of the necessary nervous control.

The great tendency of medical thought has of late unquestionably been in the direction of nerve-pathology and nerve-therapeutics. The nerve theory has in great measure—and doubtless rightly—superseded the humoral theory; and, as a result of the increased attention directed to the subject, the number of disorders found to be referable to some disease or derangement of nerve or nerve-centre, goes on ever increasing. The more, too, the ganglionic or sympathetic system is studied, the greater is found to be the number of ailments which are referable to a diseased condition of its elements. Take as a single example the great abdominal ganglionic centres, and see what a multitude of disorders can now be referred to their morbid conditions, some of which but a very short while ago were not only without a locality, but even without a name; Addison's disease; other forms of melasma; anæmia idiopathica; and probably hypochondriasis and some forms of jaundice; besides various reflected disorders, such as certain cases of mania, probably some examples of delirium tremens, and other familiar diseases and functional disorders, most of them characterised by epigastric sinking or other uneasiness.

But by far the greatest change of opinion has occurred as to the number and variety of symptoms and disorders which are now looked upon as due to causes acting at a distant part of the system, but producing their effects far from their source, through the medium of connecting nerves and nerve-tissues. Much, very much, has now been done in this direction. The work which was begun by Prochaska, continued and developed by Marshall Hall and Brown-Séquard, has indeed borne great fruit; but I venture to think that no limit can at present be set to the possible results of further investigations and inquiries in this direction. Not only have many hitherto unexplained affections been satisfactorily explained on this principle, but there seems reason to believe that the true *modus operandi* of the causes of many of our most common acute diseases may be—as some of our best thinkers have lately tried to show to be probable—through some agency of a reflex nature.

Take the simplest of all—the case of a common cold, with its resultant chill, and sore throat, and catarrh. It may indeed be true, as has long been held, that some resulting inefficiency of cutaneous action may allow of accumulation in the blood of perspiratory matters, and so give rise to some of the phenomena witnessed; but it is very plain that all the facts of this disease are by no means to be so explained, and that some further *rationale* of their action is required. Even if we leave out of the question the strange circumstance that the sore throat, or catarrh, or bronchitis, is frequently produced by merely getting the feet damp, or sitting for a few moments in a small current of air, or by exposure to other very partial cause, this old perspiratory theory—which was taught in our student days, I presume, to very many of us now present—fails to afford an intelligible explanation of the true nature of a simple cold.

But, if we allow a reflex explanation for a common cold, must we not at once agree to the further hypothesis, that all the so-called mucous inflammations of the respiratory tract—laryngitis, bronchitis, pneumonia—are or may be of the same nature and character, though differing in situation and intensity, and that they are in fact but varied results of a reflex paralysis—of a removal of the nerve-power of the vaso-motor nerves governing the vessels of the “inflamed” parts, and allowing the relaxation, congestion, and subsequent exudation of *liquor sanguinis*, in which this process of inflammation consists?

An investigation of the reason why removal of the vital heat, or vital force or nerve-power, from a given distant part, by moisture or current cold, should produce a catarrh, a cynanche, a bronchitis, a pneumonia, a rheumatic fever, would seem to be a subject worthy of the closest attention, and likely largely to increase our knowledge not only of these diseases themselves, but also of the direction in which nerve-force is apt to travel from various parts of the surface to other parts. In other words, it might lay bare the knowledge of the existence of great and definite nervous arcs or channels, of which at present we can only have a bare suspicion.

A common cold is the commonest, apparently the simplest, and certainly the most easily studied, of all these inflammations of the respiratory mucous membranes (these possibly partial reflex-paralyses. Might not the concentration of our inquiries upon the intrinsic nature of this disease unfold to us the secret history of the more serious chest-diseases, and point out to us not only their essential nature but the means of cure?

We all know and believe in the common adage, that we cannot cure a cold. Are we not fast coming also to the conclusion that we cannot cure a pneumonia, and is there any reasonable doubt that the tumid, red, congested condition, which we see in “inflamed” or catarrhal nostrils or throat, represents the exact condition of the mucous membranes lining the air-tubes in bronchitis or the lung-tissue in pneumonia? In this respect I think that practice is outrunning theory; for, whilst the essential nature of pneumonia is yet undetermined, the almost universal practice now in its treatment, in addition to the warmth of a bed, is the application of external warmth to the inflamed part by means of constantly renewed hot poultices. Possibly we might go further and do better, were we to apply this artificial warmth to the exact part from which vital heat or nerve-force was removed by the cold or wet which caused the illness. It seems reasonable to suppose that the same nervous arc or circuit through which the nerve-force was abstracted might often be the best channel for its restoration.

Assuming also that these internal inflammations are but forms of reflex paralysis, do we not see at once a reason why so-called remedies are often so useless for their check or cure, and why nothing but a certain period of rest and care, a period sufficient for the re-development of the normal nervous power of the diseased part, suffices for restoration to health? and why also rest, and chiefly physiological rest (as has recently been pointed out by Dr. Gull), is often almost the *only thing* that is needed for such restoration?

But, after all, I would ask, what is this doctrine of physiological rest, but stating in other words the need of time for the restoration of inflamed, *i.e.*, exhausted, or semi-paralysed parts? The “six weeks” that are said to be good for rheumatic fever; the four or five days that are known to be essential before a cold or a pneumonia can get “the turn” towards recovery; do but express the fact that this period of time is that in which the nerves of the part are able to recover from the exhausted condition which precedes, and allows the rise of, that particular form of disease. We may possibly neutralise the lactic acid of the blood in the one case, or the bilious or perspiratory poisons in the other, and so help to make the recovery more rapid; but in the absence of such or other complications, the rest and the vital nourishment by properly regulated warmth or temperature would seem to be the essentials of the treatment.

Before I conclude my address, there is yet one other thing worthy, I think, of mention in connection with this subject of nervous disorders, and also of some value in a practical point of view; and that is, that in considering disease and disease-causes, in this light of reflected causation, it may be worth while to remember that, as the bodies of the lower animals are not only divided into small sections, but also into the larger segments or divisions of head, thorax, and abdomen, so it is probable that some similar marked physiological division of *our* bodies also exists in the nervous sense, and that, though no anatomical line of demarcation is perceptible in the spinal cord, yet probably a definite physiological division exists defining the point of separation and of junction of the nerves appropriated to these three great segments of our bodies. Certain it is, at all events, that irritation reflected along the cord produces special symptoms which may in practice be distinctly classified in this sense, and of which we may perhaps get our best illustration if we call to mind the various symptoms produced by a *diseased or disordered uterus*, and observe how readily they may be grouped with reference to these three great segments of the body:—*e.g.*, the frontal headache, the vertigo, the puerperal convulsions or apoplexy, the mania, puerperal or otherwise, referable to the cephalic segment; the globus hystericus, the sighing and yawning, the intercostal neuralgia, the palpitation, the paralysis of upper limbs, referable to the thoracic segment; the nausea and vomiting, the abdominal pains and cramps, the pulsating aorta, and possibly the albuminous urine of pregnancy, referable to the abdominal segment. I add the albuminuria, for I, for one, am by no means satisfied with the explanation usually given of uterine pressure being the cause of this symptom, and would venture to express the opinion, founded on some observation, that not only albuminous urine, but also some of the graver seizures which are met with at the puerperal period, such as the comatose and apoplectic attacks (belonging to the cephalic segment), and the pleuritic and pneumonic attacks (referred to the thoracic segment of the body), are but examples of exhaustion of the nerve-force of the pelvic nerves producing as a result exhaustion by reflexion in these distant parts and organs.

A SON of Mr. Watkin Williams, General Secretary of the British Medical Association, has lately been elected by competition to a valuable foundation scholarship at Winchester College, being placed fourth in a list of twelve successful competitors. There were in all 111 candidates.

## ON THE PROGNOSTIC VALUE OF HÆMOPTYSIS.\*

By J. B. BRADBURY, M.D., M.R.C.P.,

Physician to Addenbrooke's Hospital, Cambridge; Medical Lecturer in Downing College; etc.

HÆMOPTYSIS is usually regarded by medical men as a symptom of such grave import, that when a patient informs us he has been spitting blood we regard it as tantamount to telling us that he is suffering from organic disease either of the lungs or heart.

The chief object which I have in view in this paper is to endeavour to show that pulmonary hæmorrhage is not a symptom of such unfavourable augury as we are apt to consider it, but that it not unfrequently occurs in persons in whom neither phthisis nor serious cardiac disease can be detected.

It will be well at the outset to enumerate the chief conditions under which hæmoptysis usually takes place, and then to consider the value to be attached to its occurrence in the several diseases of which it is but one form of expression. Expectoration of blood (exclusive of those cases in which it arises from a blow on the thorax, or from the mouth and fauces, or from ulceration of the larynx and trachea) may occur as follows: In vicarious menstruation; in hysterical women, though the catamenia are regular; in pregnant and suckling women; in the hæmorrhagic diathesis, purpura, scurvy, etc.; in bronchitis; in emphysema and asthma; in pneumonia; in pulmonary consumption; in pulmonary apoplexy; in disease of the heart and great vessels; etc.

The hæmoptysis which is vicarious of menstruation is probably the most favourable form of blood-spitting. A short time ago a young woman came to me stating that she was spitting blood. Upon inquiry, I found that she had no symptoms indicative of pulmonary disease beyond the raising of blood and a slight cough; she had not, however, menstruated *per vaginam* for a considerable time. Physical examination of her chest revealed nothing abnormal. I ascertained that the hæmoptysis occurred periodically about once a month. I accordingly concluded that the case was one of menstruation by the lungs; and the result of the treatment adopted served to confirm this view of the nature of the case.

I am aware that it has been stated, on very high authority, that these cases ultimately turn out to be phthisical, and I do not wish it to be understood that I am of opinion that all such cases terminate so favourably as the one I have just recorded; indeed, I have at present an out-patient at the hospital who every month suffers from epistaxis and hæmoptysis—in all probability vicarious of the menstrual discharge—and in whose lungs there are unmistakable signs of pulmonary mischief; still this is probably a mere coincidence, and is not necessarily connected with the diverted course of the catamenia. Dr. Pollock of the Brompton Hospital, in his work on the *Elements of Prognosis in Consumption*, writes as follows: "When menstruation is suddenly checked, a hæmoptysis is a frequent event, and may be regarded as vicarious, and with less import of pulmonary mischief than under other circumstances" (pp. 297-298).

Hæmoptysis also occurs in nervous and hysterical women, without there being any irregularity of the catamenia or any pulmonary or cardiac disease. This form usually ceases when the climacteric period is passed, and never returns.

The hæmoptysis which sometimes occurs in pregnant and suckling women is a form which is not sufficiently recognised by medical men in this country—little, if any, notice being taken of it in the English textbooks on medicine. Trousseau thus speaks of it: "There are some women who, during pregnancy, and others who, during the whole time they are nursing, spit blood; the hæmorrhage ceases spontaneously after delivery, or at the end of lactation, as the case may be, and is not symptomatic of pulmonary tubercle nor of cardiac disease." (*Clinical Medicine*, vol. iii, p. 140; New Syd. Soc.)

It is not my business to explain the cause of the hæmorrhage in the above cases, as I am only concerned with the prognosis, which, from what I have said, you will have concluded to be favourable.

Persons who suffer from what, for want of a better term, is called the hæmorrhagic diathesis, are liable to attacks of profuse hæmoptysis. A case of this kind is recorded by Dr. George Johnson, in the *BRITISH MEDICAL JOURNAL* for Feb. 12th, 1870. Dr. Johnson's patient was a blacksmith, who had frequent attacks of pulmonary hæmorrhage extending over a period of twelve years, and who, at the time of Dr. Johnson's writing, pretty certainly had no organic disease of the lung either as a cause or a consequence.

Closely allied to these cases of hæmoptysis, are those occurring in habitual drunkards, and in scurvy, purpura, and the hæmorrhagic ex-

anthemata, e.g., typhus, small-pox, etc. In all these instances we probably have a morbid tenderness of the walls of the blood-vessels, occurring without any assignable cause in the hæmorrhagic diathesis; but in chronic alcoholism, purpura, scurvy, etc., it is probably owing to a deterioration of the blood "so modifying the nutritive state of the walls of the blood-vessels as to impair their resisting power"—(Niemeyer).

If the habitual toper can be induced to indulge less in his favourite drink, the prognosis is not unfavourable. I have in my recollection the case of a young man whom I occasionally saw when I was a pupil some thirteen or fourteen years ago, who suffered from repeated attacks of this form of hæmorrhage, and who seemed completely to recover from several of them. He could not, however, be induced to forego the pleasures of the bottle, and he ultimately fell a victim to pulmonary consumption, probably induced by one of these attacks of hæmoptysis in a way which I shall presently explain. I have also a case of this kind under my care at the present time, which I am watching with considerable interest. The patient has had three severe attacks of hæmoptysis since last August, and is at the present time progressing rapidly towards convalescence from the last attack; the lung-mischief not having as yet, however, entirely disappeared.

There is one form of bronchitis with which spitting of blood is generally associated—I allude to the plastic form. In some of these cases the bronchorrhagia is the first symptom. The hæmoptysis may recur at intervals until the fibrinous casts of the bronchial tubes are expelled. Of thirty-four cases of this disease recorded by Dr. Peacock in the fifth volume of the *Pathological Transactions*, there was entire recovery in twenty cases, four became chronic, and ten died, so that nearly sixty per cent. recovered.

Ordinary acute bronchitis is also sometimes attended with the expectoration of bloody sputa, and even with copious hæmoptysis; and these are the cases in which the prognostic powers of the physician become sorely taxed. For instance, a patient has an attack of bronchitis supervening upon a severe catarrh, and during the attack the expectoration is streaked with blood. There may be no evidence of pulmonary mischief beyond the bronchitis; i.e., no diminished respiratory murmur nor prolonged expiration, nor dulness on percussion under either clavicle, nor any bronchial breathing, nor, in a word, any physical signs indicative of consolidation of the lung. Now, what is our prognosis in such a case as this? If there be no strong hereditary tendency to phthisis in the family, and if the bronchial mischief disappear under the administration of appropriate remedies, we may augur favourably of the case; if, on the other hand, the predisposition to phthisis be great, and the catarrhal symptoms in either apex be persistent, the prognosis is grave. I have at present under my care a young man of the age of 18, whose case is of the latter type, and I confess I am afraid he will become consumptive. In these cases especially, however, our prognosis must be rather a balance of probabilities than one of absolute certainty.

Blood-spitting is a more frequent symptom of pulmonary emphysema than is generally supposed. Dr. Walshe says: "Emphysema of the lung, as its anatomy would prepare us to expect, antagonises pulmonary hæmorrhage of all kinds" (*Diseases of the Lungs*, 3rd ed., p. 416.) This is a statement which I cannot endorse, for I had lately under my care two patients suffering from emphysema, accompanied with hæmoptysis, in whom the most careful physical examination failed to detect any evidence of phthisis, or of considerable hypertrophy of the right side of the heart. Cases of the same kind have been observed by other physicians, amongst whom I may mention Dr. George Johnson, who writes as follows: "In several cases of hæmoptysis that have come under my observation, emphysema of the lung has been the only structural change that I could discover." (*BRIT. MED. JOUR.*, Feb. 12th, 1870.)

Persons with emphysema of the lung frequently live to a great age; hence in these cases a favourable prognosis may generally be given. Hæmoptysis occasionally occurs in cases of severe asthma, and sometimes continues for so long a period as one month. The quantity of blood expectorated varies from a few streaks to as much as a pint. Dr. Hyde Salter says, "where it has once occurred it is very apt to occur again. . . . In one case that came under my observation, this hæmorrhage occurred for years at almost every attack. It evidently depended here on an unusual completeness of apnoea and its resulting blood-stasis; and yet no permanent injury was sustained by the lungs, and the ultimate recovery of the patient was complete". (*On Asthma*, 2nd edition, pp. 88-89.)

Acute inflammation of the lungs is occasionally attended with copious hæmoptysis, in addition to the sputa being tinged with blood. I have not met with an instance of this kind, and writers seemed divided in opinion as to what the prognosis should be—one (Johnson) regarding the hæmorrhage as unconnected with tubercle, another (Walshe) stating that such cases are "almost positively connected with tubercular disease" (*Diseases of the Lung*, 3rd edition, p. 421).

\* Read before the Cambridge and Huntingdon Branch.

All who have carefully watched the revolution which medical opinions occasionally undergo must have been struck with the recent change in our ideas as to the nature and causes of pulmonary consumption. Since the time of Laennec, phthisis has been regarded by most physicians as due to tubercular deposit in the lungs, the result of a constitutional vice, which we call the tubercular diathesis. Recently, however, the views of Dr. Addison, which had not met with the attention they deserved in our own country, and which seem to have been altogether unknown on the continent, have been revived by Niemeyer and others, who regard pulmonary consumption as by no means always the result of tubercular deposit in the lung, but as being frequently the result of pneumonia, without any deposition of tubercle, although this new formation may in some cases co-exist with the products of inflammation of the lung; but the tubercles have in the majority of those cases only developed themselves at a later stage of the disease—their development only in very few cases preceding the pneumonic processes.

The products of any of the three forms of pneumonia—viz., common acute pneumonia, acute catarrhal pneumonia, and chronic catarrhal pneumonia, may undergo cheesy metamorphosis; but the products of the latter form most frequently undergo this change, and lead to the formation of cavities in the lungs.

We may, then, have three forms of phthisis—viz., the pneumonic, the tuberculo-pneumonic, and the tubercular. The first two of these forms chiefly concern us as being connected with hæmoptysis, spitting of blood being a rare symptom in acute tuberculosis.

Phthisis caused by chronic pneumonia was not considered by Niemeyer to be a particularly dangerous disease. He says: "I do not hesitate to assert that the chronic inflammatory processes which lead to consolidation of the lung and to the formation of cavities, usually show a decided tendency to heal; and that, under appropriate treatment, persons with extensive consolidation and great cavities may often for a long time be kept in a tolerable state—nay, comparatively even in a state of good health. *The greatest danger to most phthisical patients is the development of tubercles*" (*Lectures on Phthisis*, p. 11.)

Niemeyer had also arrived at the conclusion, and rightly so, I think, that pulmonary hæmorrhage is sometimes a cause of consumption—a view which was entertained by Hippocrates, Cullen, and other old writers, who mention a "phthisis ab hæmoptoe". Cases have been recorded by Drs. Bäumlér, Weber, and George Johnson, which tend to confirm Professor Niemeyer's view; and there can now be little doubt of the fact that an attack of hæmoptysis may cause blood to be aspirated into the smaller bronchi and air-cells of the lungs, where it may act as an irritant and set up inflammatory changes, the products of which may either undergo complete resolution or lead to the formation of cheesy products, which may ultimately soften and thereby shorten life. Such an accident may also happen during the progress of phthisis, but I am of opinion that it is not so common as Niemeyer would have us suppose; and my experience certainly coincides with that of Walshe and others, who do not regard attacks of hæmoptysis, unless the hæmorrhage be very profuse, as materially accelerating the fatal issue.

It occasionally happens that hæmoptysis is the immediate cause of death in phthisis; and in these cases a rupture of a branch of the pulmonary artery in a vomica has preceded the fatal termination. Such cases are, however, not of frequent occurrence.

Unless, therefore, the hæmoptysis of phthisis be followed by an increased temperature, and by a persistent frequency and irritability of the pulse, our prognosis, *quoad* the hæmorrhage affecting the prolongation of life, need not in the majority of cases be unfavourable.

Pulmonary apoplexy, when attended with hæmoptysis, so frequently depends upon disease of the left side of the heart, especially of the mitral valve, that the prognosis in pulmonary infarction must necessarily be the same as that of the cardiac disease, of which it is a consequence, and which will presently come under our consideration. Before leaving the subject of pulmonary apoplexy I wish, however, to mention that it occasionally—very rarely, I acknowledge—proves rapidly fatal, owing to the copious hæmoptysis which attends it. I have recorded in the *BRITISH MEDICAL JOURNAL* for Jan. 14th, 1871, such a case in which the patient died within twenty minutes from the time of the supervention of the hæmorrhage, and in whose heart and lungs no organic mischief could be detected either before or after death, with the exception of a large patch of encysted pulmonary apoplexy at the base of the left lung, which was found only on post mortem examination.

In disease of the heart and great vessels, I must acknowledge that spitting of blood is a grave symptom, and that it by no means unfrequently warns us that the time has come when the physician, and the patient, too, alas! must combat to the death against which the batteries of steel, digitalis, iodine of potassium, etc., can no longer hold out.

I have already trespassed too long on your patience, and will, in con-

clusion, only remark that one of the objects which I have had in view in reading this paper has been to elicit discussion on this important subject, and to ascertain from those of greater experience than myself whether their opinions are in harmony or in discord with my own.

## NOTES OF A VISIT TO THE MILITARY HOSPITALS AT BONN, WITH REMARKS UPON THE PHYSIQUE OF THE TROOPS RECENTLY RETURNED FROM FRANCE.

By DYCE DUCKWORTH, M.D.,  
Assistant-Physician to St. Bartholomew's Hospital.

IN the course of a holiday tour, and while at Bonn, I paid a visit to the military hospitals to see the last of the wounded in the recent war, and was very kindly conducted over them by Dr. Kalt, who, although a civil practitioner, had charge for some months of a number of the cases. There are now from two to three hundred wounded men in Bonn, and they lie in huts which were hurriedly built at the beginning of the war for the reception of French prisoners. As none of the latter were sent to Bonn, many of the huts were pulled down, and the remainder converted into small hospitals. They are built of wooden framework, into which concrete has been introduced, and are placed in rows upon the Exercier Platz. A large and airy hospital has also been made in the military riding school.

The former buildings very much resemble the Camp at Aldershot in their general aspect.

I learned that the wounded came from before Metz and Paris, a few from the engagements at Wörth and Gravelotte, and many had confronted the army of General Faidherbe about Amiens and in the north of France. Only one Frenchman lay amongst them, the last of a considerable number. The cases were mostly the result of Chassepôt-bullet wounds, and some were from shells. There were many injuries to knee and wrist joints, and in not a few instances the balls were both known, and also believed to be, in the limbs. I saw no examples of conservative surgery.

On the whole, the hospitals proved very healthy, and the deaths reached a small percentage. An outbreak of hospital gangrene occurred early this year which threatened to prove formidable. Dr. Kalt employed, with the best results, the following treatment—actual cautery freely to the wounds, or pure carbolic acid in less severe cases, also wine and quinine plentifully. Every comfort appeared to be supplied to the men, and the air of the huts was quite satisfactory.

Many of the cases were quite convalescent, and while some were learning to use their crutches others were trying on wooden arms and legs. Dr. Kalt informed me that much venereal disease had befallen their troops while in France, and some severe cases of sloughing bubo, which had threatened to cause grievous loss of integument, were lying in one of the huts. Owing to great care, the ulcerations had been limited considerably. It is feared that syphilis may be found to spread in Germany, and to be introduced amongst the peasantry when the troops return to their homes, and this Dr. Kalt naturally regarded as a sad trophy of the war. He also believed the invasion of France would have a disastrous effect upon the morals of their younger soldiers, which was much to be deprecated.

Bonn seems likely to become a more important university than it has hitherto been, not but that it has always been one of the leading schools in Germany. In a few years the professors will possess almost unrivalled means of teaching technology and other applied sciences, and Bonn will only be second to the largest schools for clinical purposes by reason of the smallness of the town. At Poppelsdorf, one of the suburbs, large anatomical laboratories are being built, in addition to the splendid chemical and agricultural institutions already existing in that place, and there is at present a new obstetrical *clinique* being erected, with a river frontage, at the northern extremity of the town. Both medical and surgical *cliniques* are to be built adjoining the obstetrical one, so that remarkable changes in the appliances of the medical faculty are approaching. Bonn, like most other German medical schools, was bereft of her students last winter, as they volunteered for service in France as dressers.

While I was in Bonn the 8th regiment of the King's (Rhenish) Hussars made a triumphal entry into the town, and were received with intense enthusiasm and rejoicings. The men were in the finest possible condition, and no more active or worklike troops could possibly be seen. They were bronzed and travel-stained, and gave infinitely more

satisfaction to my eye than the smartest of our light cavalry regiments on their too well-bred horses.

At Coblenz and at Ems, also, several infantry regiments entered the town in triumph. All the men were apparently in the most robust health, and were well grown and seasoned. It may be hoped that they will keep their vigour in garrison in Coblenz. New wooden barracks are being erected for many of them near one of the now deserted French camps, but the accommodation in the fortress of Ehrenbreitstein, now, as on previous occasions when I have visited the barracks there, is simply too foul and abominable to describe. Large numbers of the Landwehr were being dismissed to their homes after their one year of hard service.

I was pleased again to observe how excellently well the men were shod. The soldier's boot, *par excellence*, is that of the German infantry—the large, easy, broad-toed Wellington boot—into which the trousers can be tucked when marching over muddy or dusty ground; and never will the British infantry soldier be fairly dealt with till he has the same supplied to him instead of an ugly ill-fitting Blucher boot with untidy gaiters. I would fain hope that we may soon see a change in this respect in our army; as also in the fashion of carrying the knapsack which, excellent as it is in the German and French armies, the weight being supported by the waist, is as bad as can be in the British service, since the weight of the pack together with the cloak is thrown cruelly upon the axillary blood-vessels and nerves.

The individual German soldier is certainly a marvellous fighting machine. His education, his intelligence, his practical professional training, and, not least, his powers of endurance and digestion, render him indeed a formidable enemy, while his devotion to his country and Kaiser is fired by the closest personal interest, which, if I may judge by what I saw at Ems, the latter takes in his troops.

Mayence, July 12, 1871.

## CASE OF CHRONIC ILEUS.\*

By R. H. MEADE, F.R.C.S.,

Consulting Surgeon to the Bradford Infirmary.

ON November 7th, 1870, I saw a married woman, about 40 years of age (with Mr. Sugden of Bradford), the mother of a large family, and then between seven and eight months advanced in pregnancy, who was suffering from vomiting in a most troublesome and intractable form. It had commenced gradually several months before I was consulted, and was thought at first to be dependent upon the pregnant state; it became slowly worse, however, and resisted all remedies. When I saw her, she was very weak and feeble, but not much emaciated; she could take food in small quantities for two or three days in succession, without much feeling of sickness, until it began to accumulate in the stomach, or, rather, in the upper part of the intestinal canal; but when this became filled, she would vomit a large quantity of yellow pultaceous matter, in appearance like pea-soup, having a fecal odour. The bowels were very sluggish, but a small natural stool passed occasionally by the aid of enemata. The patient complained of no pain, but only of weakness and prostration; and, after a free attack of vomiting, she generally felt better for a day or two. The complaint was evidently of the nature of chronic ileus, but no history could be obtained at the time of any cause leading to it. No trace of hernia could be discovered, and the enlargement of the uterus prevented any tumour or thickening of the bowels from being felt through the abdominal walls.

The urine showed no traces of disease of the kidneys, and no ulceration or other disease of the cervix uteri could be found. The patient had a slightly jaundiced cachectic look; and from the gradual way in which the complaint had arisen, and progressed from bad to worse, Mr. Sugden suspected that there might be malignant disease of the intestine.

After suggesting one of two plans of treatment which had not been already tried, and carrying them out without success, I thought it right to recommend the induction of premature labour, thinking it possible that the pressure of the pregnant uterus upon some portion of the bowels might interfere with their action. On November 16th, this recommendation was carried out. The child lived a few hours, and the mother soon recovered from the effect of the operation, which was a little hazardous in her exhausted state.

For a short time after the uterus was emptied, the patient appeared to improve, and the stomach retained more food; but all the former symptoms of ileus gradually returned, and she slowly sank and died on the 7th of February, 1871, exactly three months after I first saw her.

\* Read before the Northern Branch.

She never suffered much pain, and there were no symptoms of peritoneal inflammation; she became very anæmic, and for some weeks before death almost pulseless; but she never became much emaciated, though for some time she had taken hardly any food. The stercoraceous vomiting continued to the last.

This case was so obscure throughout, that I felt anxious to examine the body; and, consent being obtained, I assisted Mr. Sugden in opening the abdominal cavity on the day after death. We soon found the cause of the mischief; for the extremity of the vermiform appendix of the cæcum was fixed by adhesions of old standing to the small intestine, or, rather, to the mesentery close to the bowel, on the right side of the abdomen. There were no signs of recent peritonitis, but the portion of small intestine which was in a measure bound down, though not crossed, by the band formed by the appendix, was externally of a darker colour, from vascular congestion, than the neighbouring parts. The part of the bowel thus affected would be a portion of the ileum at about one-third from its commencement. The mucous membrane appeared quite healthy, and the canal was quite pervious, though it appeared somewhat contracted opposite the point to which the end of the appendix was fixed. The large intestines were quite empty, but healthy, and so were all the other abdominal organs (the only parts of the body examined).

After making the examination, the husband of the patient was particularly questioned as to whether his wife had ever had any severe attack of pain or inflammation of the bowels; and he then remembered that, during the very early period of her pregnancy, while staying at the sea-side, he found her (on going to see her) suffering from a very severe attack of abdominal pain or spasms; but as it soon passed off, he thought no more about it. The sickness began soon afterwards, and was put down to the pregnant state, and the real cause forgotten.

REMARKS.—This case is interesting in several respects. Firstly, it was rendered very obscure by being complicated with pregnancy, and it was difficult to say what influence that state had in producing the symptoms, until after the failure of the induction of premature labour to relieve them. In the second place, it shows that it is not necessary that the canal of the intestine should be obstructed or much constricted for the production of symptoms of ileus. It appears that, if the natural peristaltic and other free movements of the bowels are interfered with, their functions cannot properly be carried on, though symptoms of acute strangulation are not produced, as where the intestine is tightly constricted.

Cases of ileus from perforation of the extremity of the appendix cæci by some foreign body, and its consequent inflammation and adhesion to the bowel or mesentery, are not very uncommon; but the appendix in these cases generally acts as a band of constriction fixed across some portion of the intestine. An interesting case of this kind which I saw, was under the care of one of my colleagues (Mr. Parkinson) in the Bradford Infirmary in January 1868. The patient, a young man, had had symptoms of enteritis ten years before; and at the time of his admission, suffered from very severe pain in the right iliac region, with incessant vomiting and obstinate constipation. No remedies giving any relief, and the seat of strangulation being apparently indicated by the pain, the operation of gastrotomy was performed by Mr. Parkinson, with the consent and co-operation of his colleagues; and when the abdominal cavity was opened, the constricting band formed by the appendix was found and removed, and the patient was very much relieved, though he sank twenty-eight hours afterwards from exhaustion. In this case, a portion of the ileum was crossed and tightly pressed by the vermiform process of the cæcum, which was attached at its extremity by old adhesions to the mesentery. No doubt the strangulated portion of bowel had here been forced under the adherent appendix during some movement of the intestines, immediately before the symptoms of obstruction came on, though the extremity of the appendix had probably been fixed in the position in which it was found during a period of ten years, during the greater part of which time it had not interfered with the natural movements of the intestines.

## THE USE OF IRON IN SCARLATINA.

WITH pleasure I observe the letter of Dr. Russell Aldridge in the JOURNAL of the 12th instant. For more than six years I have adopted a treatment similar to that which he urges in cases of scarlatina, and with much success. I have preferred to use the tincture of the sesquichloride of iron, rather than the permanganate. So far as the scarlatina anginosa is concerned, my treatment and Dr. Aldridge's are strictly uniform. I shall certainly be extremely glad if the profession generally will follow our example.

ROBERT McL. FRASER.

Darlington, August 16th, 1871.

## PATHOLOGICAL MEMORANDA.

## POST MORTEM INSPECTION OF THE HEAD.

THE accompanying photograph represents an instrument which I have devised for facilitating the *post mortem* examination of the head. A real necessity existed for such an instrument; and this, after a year's trial at the Leeds Infirmary, has been found to answer its purpose well.

The instrument consists of a solid base of brass, with two thumb-screws, by means of which it can be firmly fastened to the *post mortem* table or coffin-board. Attached to the base by two strong hinges is a radial slide, also of brass, in which is fitted a steel spring or clip for holding the head, capable of being moved to either extremity of the slide, and of being held fast at any point by means of two thumb-screws. The blades of the clip are made to secure the head, as in a vice, by means of a leather strap passed through their extremities over the forehead. The backward and forward movements of the radial slide are limited by a quadrant with thumb-screw, and enable it to be set at varying angles with the base. The instrument is also fitted with clips of different sizes, and of lighter make, covered with leather, for use in the operating theatre, in cases where the head is required to be held steadily, and in which chloroform is inadmissible or otherwise unnecessary.

Leeds, July 1871.

T. R. JESSOP.

## THERAPEUTIC MEMORANDA.

## CHLORAL IN TOOTHACHE.

For some time past I have been in the habit of using chloral hydrate, not only as an internal sedative in cases of severe dental neuralgia and of caries where it was at the time inadvisable to permit extraction, but more frequently as a direct local application to the carious tooth. A few grains of the solid hydrate introduced into the cavity of the tooth upon the point of a quill, speedily dissolve there; and in the course of a few minutes, during which a not unpleasant warm sensation is experienced, the pain is either deadened, or more often effectually allayed. A second or third application may be resorted to if necessary. The hours of agony that various circumstances may otherwise entail, are in this way avoided; and in the last instance under my notice, a young lady in a delicate state of health, suffering intensely from a carious tooth, received immediate relief from this application. She lived at a great

distance from a dentist, and was unwilling to have the tooth extracted without some anæsthetic; and the chloral hydrate was the means of obtaining a sound night's rest. I find in my notes her own report that "the toothache was relieved in a few minutes; aching did not return all night; and when it did in the morning, was again stopped by the same means."

Kirkby Lonsdale, Westmorland.

DAVID PAGE, M.D. Edinburgh.

## REPORTS

OF

## MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

## LEEDS GENERAL INFIRMARY.

## CASES TREATED BY ELECTRICITY.

(Under the care of Dr. CLIFFORD ALBUTT.)

II. *Hemiplegia*.—The following cases of hemiplegia, among others, are, or have recently been, under treatment at the Leeds Infirmary.

CASE I.—Mrs. B., a healthy mother of a family, aged about 40, was brought to the hospital, hemiplegic on the right side. She was quite unable to stand, and the right arm was useless. The history pointed pretty certainly to embolism of the left Sylvian artery, which accident had taken place about five months before. Her speech, which had been slightly affected, was now natural, and her limbs, before unmovable, could now be moved a little in bed. She had been under careful medicinal treatment at home, and her general health was fairly good. The muscles of the affected limbs were somewhat wasted, but only so far as disease would account for; their susceptibility to faradism was diminished, but was still present in considerable degree. Faradism was ordered to be applied to the nerves and muscles of the arm and leg daily. In a week the patient could move the arm and leg more freely; in a fortnight she was out of bed; in a month she was walking with ease; and in five weeks she returned home able to use her arm well, and to walk—with a limp, it is true—but with ease enough for all practical purposes. The muscles of the right limbs had recovered much of their normal tone and volume.

CASE II.—Murdoch, a man about 50 years of age, but prematurely senile, and with stiff and tortuous arteries, sallow complexion, and urine of low specific gravity, was seized, about four months before admission, with a fit, attended with unconsciousness and with left hemiplegia. A hæmorrhage into the right encephalic centres seemed a certain diagnosis. On admission as out-patient, he could hobble about with difficulty, but his arm was behind his leg in recovery. He could scarcely grasp any object; he could not hold his stick in the left hand, nor could he make with his arm any movements of pronation, supination, abduction, elevation, etc. By resting the elbow upon the table, he was just able to feed himself with the hand if required to do so. He was ordered to attend three times a week for faradism. His limbs were found somewhat wasted, but still preserving a degree of reaction, and in a few weeks he could perform all movements with the fore and upper arm and with the hands. He could throw the arm quickly above the head, whirl it round, pronate and supinate the hand, clasp and unclasp the fingers, and so forth. There remained, however, a decided deficiency of grasp in the left hand. The leg improved in like manner, but was from the first better than the hand.

CASE III.—Another patient was in the house at the same time, suffering from right hemiplegia and aphasia, of ten months' duration, due probably to a sudden occlusion of a syphilitic artery while he was sitting on a chair in a shop. He presented the following characters. The right leg had advanced a good deal towards recovery, and he could walk freely, but with a limp; the right hand and fore-arm were fairly good in rapid opening and shutting of the fingers, though behind the left; pronation and supination were fair likewise; but in the upper arm there was palsy, which grew worse in the higher muscles. The biceps and triceps muscles were weak, while the deltoid and scapular muscles were almost entirely palsied. The pectoralis major was weak like the biceps. The voice was decidedly affected; but words, though hesitating, were never lost, as they had been before. Faradism was ordered in this case also. The leg remained almost stationary; the muscles of the fore-arm improved a little, but a very striking change was seen in the deltoid, scapular, and humeral muscles. After a very few applications the patient could perform movements with the humerus, and in a fortnight could throw the arm freely up in the air. No other parts but the right limbs were faradised, and the voice remained unaffected, or rather it became a little but decidedly worse.

CASE IV.—In the fourth case there was hemiplegia in the left arm and leg, due probably to syphilitic disease of the encephalic arteries. The palsy was of ten months' standing, and both limbs were wasted and much contracted. Galvanism was ordered to the encephalon directly, and to the nerves and muscles of the limbs; these latter were likewise faradised. There was some reaction to the galvano-contraction, and much deficiency in farado-contraction.\* He derived no benefit whatever after a fortnight's treatment, and was discharged incurable.

CASE V.—The fifth and last case which we shall now report was one of a young woman who was attracted by the recovery of Mrs. B. (Case I) to the Infirmary for the purpose of electric treatment. She had great weight, weakness, and numbness, of the right arm and leg. Her age was 22. Her menstrual functions were much disordered, and she had some leucorrhœa. Faradism did her more harm than good; galvanism applied to the limbs did a little, but very little, good; but careful regulation of the menses, suppression of the leucorrhœa, and steel tonics, relieved her.

Dr. Clifford Allbutt said that the foregoing cases were good examples of the kinds of hemiplegia which the medical man was called upon to treat. In the first three, electricity was of great and astonishing benefit; in two, neither form of it was of the least value. The last case was one of those of functional hemiplegia in women which were fully described by Dr. Allbutt in this JOURNAL some months ago (October 1st, 1870). In that communication he stated that in his previous cases neither form of electricity was of much value compared with medicinal regulation of the uterine and intestinal functions, and the administration of tonics. Case IV was too far gone for much relief; there was probably extensive encephalic degeneration, consequent upon syphilitic arterial disease; and, moreover, the nerves and muscles of the limbs themselves had undergone grave trophic degenerations of a secondary character.

Leaving these cases on one side, the relief of the first three may well give rise to much interesting speculation. The methods of electrical treatment of encephalic hemiplegia are three; namely, by direct application of the continuous current to the encephalon itself, by galvanising the sympathetic in the neck, and thus reaching the encephalon indirectly; and, thirdly, by local faradisation, as already described. Dr. Allbutt said that the first two methods really do not deserve the name of method at all. The first process was introduced by Remak, and is much favoured at the present time by Benedikt. It has been proved, no doubt, by Erb that the skull and membranes offer little resistance to the passage of the current, and that the encephalon can undoubtedly be galvanised; but this is the one single fact which lies in the midst of a waste of loose assertions and random applications. No cautious person can allow that process to be dignified by the name of a method which consists only in a casual galvanising of the head, without any rule or any distinct notion of the limits within which the agent is valuable. It is admitted even by Benedikt himself that galvanism of the encephalon may be attended with very grave or even with fatal consequences; and yet he urges its use without offering any indications for or against it in particular cases, and without distinguishing, save in the loosest way, the particular benefits to be attained. It is not, indeed, to be required of any therapist that he must explain the mode of action of his remedy before recommending it; but, if we grant this immunity, we shall look the more rigorously for evidence that he has minutely investigated those facts which belong to his own department. It is absurd to tell us that a certain hemiplegic began to move his limbs after an application of the current to his head; we must have a series of such cases carefully recorded, with their varying phenomena and results marked out. Dr. Allbutt believes that hemiplegia, more than any other palsy due to organic disease, is susceptible of relief under strong mental impressions of any kind. This source of error must, therefore, be especially guarded against. Again, the state of the muscle, before and after the application, must be more adequately recorded, and the precise results not only noted at the time, but also for some subsequent time, in order to ascertain their permanency. Again, it is quite insufficient to say that galvanism was applied to the head; the observer must say exactly how it was applied in each case, and he must distinguish, as far as may be, between the effects of various doses† and between the action of the positive and negative poles, which are endowed with very opposite properties. Dr. Allbutt's own opinion is, that galvanism, applied directly to the encephalon, is very injurious so long as any active change is going on within it, but that, when the disordered parts have recovered their stability, then such applications seem to be of value in restoring the normal molecular activity. This is analogous to its action

in cases of overwrought or depressed brain, when 'very gentle direct applications of galvanism are useful, together with rest, good nourishment, and other remedies. The use of direct galvanism, with the hope of promoting absorption of effused products and the like, as we so often hear, he believes to be both useless and dangerous. The application of galvanism directly to the sympathetic, in the hope of reaching the encephalon, Dr. Allbutt says is not in any way more deserving of the name of a method. It lacks, indeed, the first basis of the former scheme; for we do not know, in the first place, whether we can influence the cervical sympathetic in any definite and decided way at all; and if we can, the evidence at present is against such influence being translated to the brain proper. The conclusions of Donders and Callenfels, so often quoted in proof of secondary effects seen in the vessels of the pia mater on cutting or irritating the cervical sympathetic, have been denied by every one who has repeated the experiments. Then, again, the central ganglia have a different supply from that of the convolutions; and, finally, how do we know that working upon the vessels will help the brain to mend itself? or whether, if it do, contraction or relaxation is the means required? The careful comparison of the alleged effects of various doses can alone settle such points; and we know of no such series. It is far from unlikely that the effects attributed to a galvanised sympathetic are due to reflex action, and may be called forth by any strong impression upon the cutaneous nerves of the region.\* We have much physiological evidence of such modes of action, and we have clinical evidence also in such cases as the effect of cold douches or blistering the nape in dissipating coma. Therefore, the effects of galvanising the tract of skin overlying the sympathetic must be compared with the effects of irritating other tracts in the neck. Dr. Allbutt has done this, and finds the results of galvanism to any part of the neck to be much alike, and to resemble the effects of a blister to the same parts. We are thus brought to localised faradisation as the only method deserving the name of a method.

No one who has read Duchenne's thorough analysis of the clinical results thus obtained can doubt that here we have a method, and one of some value. Its results awake in us many curious speculations. How is it that a hemiplegic patient may be thus strongly affected by a remedy applied to the limbs? It has been made tolerably clear that localised faradisation of the limbs has little influence beyond the limbs, and in particular has little effect, and perhaps none, upon the centres. It may, therefore, be used gently very soon after an attack of hæmorrhage; and Dr. Allbutt, indeed, advises its cautious application from the time that the symptoms of central perturbation have passed away. The great relief often given by one application in a case of some standing like those above quoted make one error very clear to us, and that is the mistaken belief that the degree of the palsy is a measure of the amount of central mischief in apoplexy; and it makes it clear, moreover, that those writers are wrong who urge central applications rather than peripheral on the ground that to electrify the periphery is to be led away from the true seat of the disorder. It is absurd to suppose that a man takes up his bed and walks after a few days of faradism, because the faradism has affected his corpus striatum or its vessels. It is clear that some modification of nerves or muscles in the limbs themselves is produced. It would seem that, after a hæmorrhage, say, there is a tendency in the affected parts to rest in the hemiplegic state long after the centres are, in a measure, restored. There must be some perpetuated habit or state of innutrition which needs dispersion. The results of acupuncture in cases of muscles palsied by disease, lately published by Mr. Teale, are probably of a kindred nature, and often much resemble the effects of faradism in the manner of their appearance. The third case recorded above helps us curiously in this discussion. This man presented, what we so often see, a fore-arm recovered and an upper arm still palsied. How is this to be explained? Probably in this way, that an invalid tries to use his fingers and hand for little immediate wants from an early period of his illness; but he is not called upon so much to arouse his upper arm, which remains helpless accordingly. In this way may, perhaps, be explained the earlier recovery of the leg in some cases, as one of the patient's first hopes and requirements is to test his power of standing and walking. It is not until much later that he tries to move his whole arm in any vigorous or regular way. The same may be said of the voice, which often recovers early, and which is exercised and solicited with anxious hope from the first days of the illness. Of course much must depend upon the precise seat of the central mischief; but if it be, as Dr. Hughlings Jackson suggests, that each part of the limbs is represented in every part of the corpus striatum, we can understand that, on partial destruction of the centre, we should have to expect not complete circumscribed palsies, but a general loss of capacity throughout the limbs. Add to this the tendency of the voluntary organs

\* It is often difficult to estimate slight losses of farado-contraction, as the reaction of the two sides often differs in health.

† Dr. Rutherford has done much to add to our experimental knowledge in these particulars.

\* Irritation of branches of the fifth nerve upon the face with the dry pole of an induction-coil may set up serious intracranial disturbances.

to sink into habits of inaction, and we have some means of explaining their recovery on application of the faradic stimulus, without the necessity of supposing that the portion of the centre once destroyed is ever rebuilt. Nothing is more unlikely than that faradising the limbs can rebuild it. Finally, the same course of reasoning would lead us to anticipate that a recovery of this kind must always be incomplete: and this is so. These paralytics after faradisation never, or scarcely ever, recover entirely, but they attain a certain point beyond which there is no advance. Dr. Allbutt even thinks that the continued application of faradism when this point has once been attained is not only useless but injurious. In more than one case he has seen ground distinctly lost by pushing the treatment beyond this point of compromise; and he thinks that in the careful use of the interrupted current we have the best test for the amount of central mischief. It is clear from what has gone before that the amount of palsy is of little value as a test of the amount of central mischief, for in some cases, as in the case of Mrs. B., a bad hemiplegia may clear up so far as to show that the amount of central destruction is by no means great, and that the palsy bore an accidental rather than an essential relation to it.

**ERRATUM.**—In the previous section (Infantile Palsy, June 17, 1871), a confusion between the first and third persons was due to the omission of some marks of quotation.

### THE DARLINGTON HOSPITAL.

#### CASE OF HYDROPHOBIA: DEATH: REMARKS.\*

(Under the care of Dr. J. R. FOTHERGILL, Physician to the Hospital.)

J. N., forty years of age, a farm-servant, was bitten on July 13th, 1870, in the little finger of the left hand, by a stray dog, which afterwards proved to be mad. The wounds healed, and he remained in his ordinary health until Thursday, August 11th. Previously to this date, he had always enjoyed excellent health, and he was of industrious and temperate habits.

On the night of August 11th, he became very ill; he had little sleep, was extremely restless, and had severe rigors. He went out in the morning, still feeling ill and unfit for work, and fell asleep in the field on his hands and knees. During the afternoon he felt great thirst; and, on some water being brought, he found himself quite unable to drink it. He again passed a restless and sleepless night; and the next day (Saturday, August 13th) he was seen by Mr. Cockroft of Hurworth. The symptoms noticed on that occasion were loss of sleep and appetite, and change of manner. The patient said there was nothing the matter with him. Mr. Cockroft saw him again on Saturday, the 14th. He found him in bed. He was wild-looking and restless, and complained that he could not drink. When offered fluids, he had violent spasms, and respiration was difficult. Hyperæsthesia was well marked, and he was very irritable. He was then sent to the Darlington Hospital.

On admission, he was in a state of great nervous excitement, talking constantly, but connectedly; and, on being offered a glass of water, he appeared to tremble with fear, started back, and begged it should not be brought near him—complaining at the same time of great thirst. When Dr. Fothergill arrived, the patient was in bed. He was quite sensible, and able to converse, although there was much excitement of manner, and twitching of the facial muscles. He complained of pain in the little finger of the left hand, extending up the arm and over the left side of the chest. He said that he could not swallow fluids; and, when some water was offered to him, he shuddered and drew back, his face becoming fixed, and his whole body appearing convulsed. When, however, he was induced to shut his eyes, and some water was put into his mouth with a teaspoon, he succeeded in swallowing it, though it produced tremors of his whole frame. In consequence of the distress produced by the sight of liquids, and as at the same time he could swallow them when he did not see them, and considering their ingestion as the first step towards relief, a long flexible tube was procured, and one end placed in a tumbler of water, carefully covered with a cloth. He was easily induced to place the other end of the tube in his mouth, and to swallow, though with some effort, about half a tumbler of water, with which he seemed pleased and refreshed. He was ordered to take water, beef-tea, and milk, through the tube; and to have a dose of chloral at bedtime. His pulse was 63, of good strength. The tongue was covered with a brown fur.

July 15th. He had passed a restless night, having slept about half an hour in snatches. He had taken through the tube about two tum-

blers of water, also a cup of tea and two eggs. He swallowed with less difficulty, but still with an effort; the rigidity of the chest when fluids approached him being well marked. He still complained of the pain in the left finger, up the arm, and over the left side of the chest; and also said (indicating his hyperæsthetic condition) that the ward was too large and lofty, and that the air felt very cold as it went down his throat and into his chest. Pulse 86; tongue moist, but covered with whitish-brown fur. As his bowels had not been moved, he was ordered an ounce and a half of black draught; and, to relieve the spasm, half a drachm of bromide of potassium every four hours.—9 P.M. His bowels were moved at noon. He took two cups of tea and two eggs about 4.30 P.M. He had passed a quiet afternoon, and said he felt better. He had passed ten ounces of urine during the twenty-four hours. Pulse 80; temperature 100.8 deg.

July 16th, 10 A.M. He had had several hours' sleep during the night, but with considerable excitement during the intervals. He had had eggs and beef-tea, and had fed himself with a spoon. At Dr. Fothergill's request, he took a tumbler of water in his hand, and, though slightly agitated at the idea of it, drank it off. He complained of numbness of his hands. Pulse 88, irregular; temperature 101.8 deg.—10 P.M. He had taken plenty of beef-tea and other food to-day. His manner was still excited. Pulse 96, irregular; temperature 101.8 deg. The bromide of potassium was discontinued. Stimulants were ordered.

July 17th, 10 A.M. He had passed a quiet night, having slept four hours. There was much less agitation, although the twitchings of the facial muscles continued. He still took beef-tea and eggs, but asked to be fed, instead of feeding himself. There was decided numbness of both hands, and inability to use them. He could raise them to his neck, but could not unbutton his shirt-collar. Pulse 92; temperature 100 deg.—9.30 P.M. He had passed a quiet day, almost free from excitement. There was no twitching of the facial muscles. He took food freely, but preferred to have it given. He still complained of the numbness of his hands. His memory was decidedly impaired. Pulse 96; temperature 100 deg.

July 18th, 10 A.M. He passed a restless night, having slept about half an hour. The twitching of the facial muscles had reappeared. His mind was confused and wandering, though he could answer questions rationally. The paralysis had extended to the lower extremities to such an extent that he could not stand or make any use of them. Pulse 92. Temperature 100.4 deg.—9.30 P.M. He slept about six hours during the day. The attendant stated that, when he awoke, he "sobbed for about half a minute, as if he would suffocate." There was no twitching. Pulse 88; temperature 101 deg.

July 19th. He slept at intervals, about an hour altogether. There was no excitement. The general paralysis was marked. He could feed himself or get out of bed, although his appetite remained good. There was muco-purulent secretion from both eyes. The tongue appeared morbidly red through a thin white fur. Pulse 84; temperature 99.8 deg.—9.30 P.M. He had slept two hours; there was no sobbing on awaking. He had no twitching of the facial muscles. The paralysis continued. Pulse 92; temperature 101 deg.

July 20th, 10 A.M. He had had many hours of sleep. His mind was wandering. The paralysis was still more apparent. There was increased secretion from eyes, and saliva ran out of the corner of his open mouth. Pulse 100; temperature 102 deg. The breathing was shallow.—9 P.M. He was much the same. He had slept most of the day. He refused both food and drink. Pulse 76; temperature 102 deg.

July 21st, 10 A.M. He passed a quiet night, and was much in the same state as yesterday, but unconscious. Pulse 120; temperature 103.4.—9 P.M. He appeared to be sinking fast. Pulse 116; temperature 103.4 deg.

July 22nd. He died about 10 A.M. A necropsy was made forty-eight hours after death. The head, spinal cord, thorax, and abdomen were examined. All the organs were congested, but were apparently otherwise healthy. The nerves of the bitten finger were examined, and were healthy.

**REMARKS BY DR. FOTHERGILL.**—The chief points of interest in the case appear to be, firstly, that by the use of a long tube with the fluids concealed, the patient was able to take them with great comfort to himself and with probable prolongation of his life; and, secondly, the length of time that he lived, and the mode of death. He died on the twelfth day. Having escaped death by spasm of the respiratory muscles, or by starvation, he died apparently from paralysis of the respiratory muscles. Should future experience prove that food and medicine can be administered in such cases by means of the tube, one step will have been gained towards the treatment of the disease.

\* Read at the annual meeting of the Northern Branch.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, SEPTEMBER 2ND, 1871.

### THE NAVAL MEDICAL SERVICE AND THE PLYMOUTH MEETING.

THE medical officers of the fleet and naval hospitals at Plymouth showed a ready and warm courtesy on the occasion of the annual meeting of the Association at Plymouth which deserves our cordial acknowledgments, and will, we trust, cement more strongly the fraternal union which should exist between the Army and Navy Medical Services and the British Medical Association. When the arrangements were in progress for the reception of the Association, they entered into the general desire of the resident profession to meet the occasion with a spirit and liberality, which should adequately welcome the coming congress and reflect permanent credit on the locality. With this view, although not to be classed as permanent residents, they took their part in the guarantee fund and assumed a share in the pecuniary responsibilities incidental to the reception. Immediately before the meeting a special message was received from Sir Alexander Armstrong, the Director-General of the Naval Medical Department, one of the most energetic members of our Association, who was personally and intimately cognisant of those efforts by which the British Medical Association, under the immediate impulse of Dr. Markham and Dr. Stewart, secured for the service the Committee on pay and promotion of naval medical officers, which led to all the recent improvements. Sir A. Armstrong requested that the fullest facilities might be afforded for the members of the Association to visit the naval hospitals. Dr. Davidson, the Inspector-General in charge, Dr. Bernard, and Dr. Irwin, accordingly took measures to secure a reception for all members visiting the wards. The Committee of Council of the Association at its first meeting passed a special resolution inviting all the members of both services to assist at the meetings and receptions, and investing them, without distinction, throughout the meeting with the full privileges of honorary membership. This resolution was immediately printed and posted at the reception-rooms and hotels. In compliment to the two services, moreover, Inspector-General Smart, C.B., R.N., and Deputy Inspector-General Longmore, C.B., had been invited to accept the Vice-Presidency of the Medical and Surgical Sections respectively. Owing, however, apparently to some defect in the communications between the local officers and the representatives of the services, these respective and mutual attentions were by no means so thoroughly known on either side as it was desired they should be. It happened, unfortunately, that both Sir A. Armstrong and Dr. Smart, whose presence was confidently reckoned on, were unavoidably prevented from attending; and the medical officers of the services did not receive the timely intimation of the arrangements of the Association to receive them as honoured guests which would have secured their presence in

the numbers desired. Those of our associates who visited the Naval Hospital saw one of the earliest establishments in which the true principles of hospital construction were first appreciated and applied in this country, whence they have been copied into others, as Mr. Whipple demonstrated by the quotation from Tenon in his address. We have since gone beyond this model in many respects; and something might be done to improve the through ventilation of the pavilions by breaking full-sized window-openings in some of the party-walls, as has been done, for example, to remedy a similar defect in the much more recently constructed medical wards of St. Mary's Hospital, London. The practice in the wards is of the most advanced and scientific character. The admirable results attained by Dr. Bernard, when in charge of the surgical wards, by his intelligent and successful application of Mr. Lister's antiseptic methods, have already been published in the *Naval Medical Report*, and announced in these columns, and were specially mentioned by Professor Lister in his address. Dr. Irwin is carrying on this practice with, we understand, equally successful results. Very few hospitals in civil life can show such excellent results as are achieved in these wards by a strict adherence to antiseptic principles. In the treatment of some common but troublesome affections, the antiseptic method effects a saving of time which is valuable in all cases, but of which the precise value is more easily measurable in the public services than elsewhere. By opening buboes of the groin, for example, with antiseptic precaution, and employing with proper care the prescribed dressings, we understand from Dr. Irwin, it is found that further suppuration is arrested and cure very quickly effected. Dr. Bernard, in the medical wards, is carrying on an extensive series of sphygmographic observations, for which the frequent occurrence of cases of aneurism affords good opportunities. The clinical books of these wards are kept with admirable care and accuracy, and are being rapidly enriched with a fine series of graphic illustrations. The first batch of Netley graduates has arrived, and some are in practice at the Hospital. The Museum contains a few specimens of much interest, many of them recent; but it by no means adequately represents the pathological opportunities which are afforded by an institution such as this, where there occur, we believe, about three deaths in a week. Nor is it at all likely, or even possible, that it should do so, until a special officer is detailed for the post. The office of pathologist to this Hospital is one which would be most properly filled, under the direction of the principal medical officers, by some one of the more distinguished Netley graduates, who had received there an adequate training and had manifested a taste and fitness for pathological investigations. It would be an excellent opportunity for further training and exercise in pathological investigation. The Director-General of the Medical Department of the Navy will not need any argument to satisfy his mind of the advantages to the public service of the complete scientific training of his corps, and the propriety of the full utilisation of the material and resources of the establishments which he directs. At present, the Museum at the Naval Hospital at Plymouth is not worthy of the service or the country, and is only redeemed from insignificance by a few excellent specimens testifying to excellent operative skill and capacity on the part of naval medical officers. Besides placing the pathological department on a satisfactory footing,

there is some useful work to be done in reorganising the nursing. At present the female nurses or sisters of the ward, and the under-nurses or scrubbers, appear to be paid alike. The consequences do not appear to be satisfactory. A somewhat higher class of nurses might be secured, we think, with advantage, and perhaps without extra expenditure, by a better apportioning of the salaries; and by applying to the Nightingale establishment of St. Thomas's Hospital, an improvement in this part of the *personnel* might be effected which could but be advantageous to the patients and just to the medical officers. The general administration of the hospital would thus be on a par with the professional care of the patients, which is excellent.

We cannot conclude these brief notes of a short visit without a word of commendation for the baths, which are of white marble and excellently arranged. They are, we believe, a recent addition.

The medical officers of the fleet, the surgeons of the *Agin-court*, and Staff-Surgeon Wells, were equally courteous and warm in welcoming our associates, with the medical officers of the naval hospitals, and to all our thanks are due. While regretting that more was not made of this opportunity of drawing closer the bonds which unite our brethren in the services to their colleagues in the British Medical Association and in civil life, we may express the hope that some good may come of this brief opportunity for intercourse. The British Medical Association has already found opportunities of rendering the most important services to naval and military medical officers here and elsewhere. It would be desirable on all accounts that by joining the Association in greater numbers the medical officers should enter more intimately into the movement of medical life and science on shore, and avail themselves of the weekly opportunities afforded by the *JOURNAL* of exchanging thoughts, experience, and sympathies, with the great body of their common profession. It is our wish to cultivate the closest relations with our naval and military brethren, and to forward in every way their professional, social, and scientific interests.

#### THE GEOGRAPHY OF PHTHISIS.

THE investigation of the geographical relations of disease has of course a special importance in indicating places of refuge to which we may direct those suffering from diathetic predisposition to constitutional affections. Localities traditionally free from scrofula or from phthisis presumably enjoy physical advantages which have procured them that immunity, and offer prospective advantages of residence to persons who have reason to fear attack, or in whom already symptoms of constitutional taint or individual susceptibility are already developed. The study of these physical conditions has a yet wider scientific and therapeutic importance. It is possible that by a scrutiny of the climatic conditions, of the soil, elevation, water-supply, diet, or modes of life, characteristic of the favoured regions and of their inhabitants, we may discover facts bearing upon the general causation of these maladies, and leading to a clearer perception of their pathology and the means of arresting their extension in places where they are prevalent. Dr. Charlton of Newcastle, in an interesting paper, of which we have recently received a copy, but of which only a limited number have been printed, has discussed some of the peculiarities of those regions where phthisis is unknown, and has pointed out some curious facts worthy of further study. The following countries are enumerated as being undoubtedly free from phthisis: Iceland and the Faroe Islands; the Kirghis Steppes of Russia; and the elevated plains of the Andes in South America. In Shetland it was rare until the beginning of the present century. Analysing the conditions of life

and climate, he points out that in Iceland it is certainly not the cleanliness of the people, their diet, or the purity of the air in their dwelling-houses, that produces the immunity in question. The Icelandic washes as little as the Norwegian peasant, who is said to come into contact with soap and water but twice in his life—viz., at his birth and at his decease. The Icelandic dwellings are models of unwholesomeness; and the food, consisting of stock-fish and rancid butter, is pre-eminently difficult of digestion. In Faroe, the sanitary condition is described as little better. The houses are not quite so nearly subterranean dwellings as those of Iceland; more milk, perhaps, is drunk, and more flesh-meat is eaten, but both fish and flesh are preferred in a putrid state. Few of the Iceland or Faroese houses are situated much above the sea-level. In the Kirghis deserts a nomad population of nearly a million souls lives entirely free from phthisis. These deserts are actually one hundred feet below the sea-level—a most untoward circumstance for those who maintain that phthisis is never to be found at a certain elevation. It has been suggested that it is the diet of the Kirghese which preserves them from phthisis. Their principal drink is the fermented mare's milk or koumiss, an agreeable subacid and slightly intoxicating beverage; and to this the immunity from pulmonary phthisis is ascribed. The advocates of this theory would have been greatly delighted, says Dr. Charlton, had they known that in Iceland and Faroe the favourite drink is a partially fermented liquor, named *blanda*, and that, in proportion as this drink has been left off in Shetland, where we often enjoyed it forty years ago, so has phthisis increased in the latter islands. In accordance with this theory, koumiss establishments were formed near St. Petersburg, and even in Germany; but after some years of trial they were relinquished, and it was decided by the medical profession of Russia that, to profit by the koumiss treatment, it was necessary to go and drink it in the Kirghis desert. There is no doubt, however, in Dr. Charlton's mind, that, like cod-liver oil, koumiss is a most wholesome and fattening and beverage, that, unlike cod-liver oil, it seems to rarely disagree with the weakest digestions.

No climatic question has been recently discussed more vigorously than that of the influence of high elevation on the arrest of phthisis. Dr. Charlton analyses some of the evidence on this subject. Brehmer maintains that, in Northern Germany, phthisis hardly exists at an elevation of 1,700 feet above the sea, but that the line of safety rises to a higher point as we go southwards. He has himself high-level stations for consumptives, at about 1,800 feet above the sea, in North Germany. At St. Moritz and elsewhere in the Engadine, English consumptives are now braving the climatic severities of "an almost arctic winter", at stations upwards of 5,000 feet above the level of the sea. At the Andes, on the high-level plains of Carmarca, 8,000 to 10,000 feet above the sea-level, nearly upon the equator, phthisis is unknown. It is common along the low coast-line of Peru; but the better classes there find safety in flight to those plains when the early symptoms are developed. Should they return to live in Lima, the disease may recur; but on the high-level plains it makes no progress. Brehmer believes that phthisis is mainly ascribable to a want of vigour of the circulation; and he ascribes the beneficial influence of high elevation to its powerfully tonic influence on this function. The equal immunity enjoyed by the residents at the low level of the Kirghis steppes he has not explained. He accounts for the like privilege of the Icelanders by the supposition that they have naturally an accelerated pulse. Unfortunately for his theory, says Dr. Charlton, it was pointed out more than sixty years ago, by a yet living observer, that the pulse of the Icelanders is peculiarly slow.

After all, therefore, our author concludes that we cannot really at present account for the immunity of certain localities under such very opposite conditions. A drink of half-fermented whey, the koumiss, which was specially introduced to the notice of members at the recent meeting at Plymouth, is a leading and peculiar article of diet common to the Icelanders, the Faroese, and the Kirghese; but it is unknown on the high levels of the Andes. We have yet to learn how far the immunity of the high lands of America is borne out by the life-history of the in-

habitants of the newly discovered high lands of Central Africa. Dr. Charlton's conclusions are that, while we admit the probability of the influence of the fermented drink, the blanda and koumiss, among the Icelanders, the Faroese, and the Kirghese tribes of Russia and Tartary, we cannot deny the good that is effected by a residence at the altitude of 2,000 feet and more for consumptives. It is possible, he thinks, that phthisis may be fostered by some vegetable miasm or sporules which may not exist at great elevations, in the dry sandy steppes of Kirghis Tartary, or in the bitter cold of Iceland and Faroe. We can imagine an increase of ozone at great elevations; we can hardly hope to find it so in the steppes of Tartary. Here we begin to turn the leaves of pages yet blank in the book of knowledge, and which await the superscription of some future successful student of our art.

SIR R. MURCHISON has received from Dr. Kirk, British Consul at Zanzibar, a letter, in which he states that Dr. Livingstone is moving slowly but safely towards the sea-coast.

DURING the week from July 30th to August 5th, there were 156 deaths in Florence, of which 24 were from diphtheria (which has been epidemic there), 8 from small-pox, and 7 from typhoid fever.

THE mortality in Paris during the week ending Friday, August 25th, was 823. There were 79 deaths from diarrhoea, 16 from cholera, and 6 from cholera.

THE Library of the Obstetrical Society of London will be closed from Thursday, September 7th, to Wednesday, September 20th, both days inclusive.

IN the *Court Circular* of Sunday we read: "The Queen has been suffering from severe sore-throat, headache, and grave general illness. Although greatly better, Her Majesty was not sufficiently recovered to attend Divine service."

IN his last quarterly report, the Registrar-General stated that, of all the principal English watering-places, Folkestone had the lowest death-rate. It also appears that for ten years past Folkestone has held the same enviable position, the mortality having averaged 16.4 per 1,000.

THE Norwich magistrates have committed for trial for manslaughter a midwife named Sarah Martin, for causing the death of a woman, whom she was attending in her confinement, through being intoxicated.

AT the West Derby Workhouse, Liverpool, in the year, with a population of under a thousand persons, as much as thirteen hundred pounds' worth of excisable liquor has been consumed under medical certificate. A committee has been appointed to inquire into the matter.

THE Austrian Ministry has declined to comply with the request of the College of Professors, supported by the Consistorium of the University, that Professor Karsten should be suspended from taking part in the examination of candidates for the degree in medicine.

A SOCIETY for the relief of persons apparently drowned—for the same purposes, in fact, as the Royal Humane Society of this country—has lately been instituted in Leghorn by a philanthropic physician of that place, Dr. Giacomo Ancona. This is the first institution of the kind which has been formed in Italy.

IN accordance with the will of the late Dr. Lacaze, a prize of 10,000 francs is to be awarded by the Faculty of Medicine of Paris every second year to the best work on phthisis and on typhoid fever alternately. The first prize will be awarded at the end of the academical year 1871-2, for the best work on phthisis. Essays (with a distinguishing motto and the author's name in a sealed envelope) must be sent in before July 1st, 1872. The prize is open to foreigners.

AN additional contribution of £1,000 has been made by "G. R. F." to the funds of the Metropolitan Convalescent Institution, Walton-on-Thames, Mitcham, and Hendon.—Mr. John Stone has made a third donation of £100 to the Worcester Infirmary.

#### FOOD FOR MARCHING REGIMENTS.

COLONEL SHAKESPEAR, with a great appreciation of the evils of a commensariat including meat killed in the morning and boiled hard for an hour in the afternoon, suggests that Australian tinned mutton, warmed up with potatoes, makes an unexceptionable hunter's stew, and affords a ready means of providing a rapid camp-meal at half an hour's notice for the Berkshire campaigners. For campaign purposes, the virtues of the Swedish felted cans have never yet been properly utilised. With these, half an hour's fire in the morning keeps the food slowly stewing on the march, and supplies a tender and savoury meal, ready at the halt.

#### METROPOLITAN PITFALLS.

THE epidemic character of particular kinds of accidents has been a frequent subject of casual comment; and it is sometimes difficult to accept the assurance of statisticians that such accidental accumulations are only apparent, and not real, aberrations in the operation of cyclical laws. Just now we have an epidemic in the metropolis of cesspool-accidents, from the rotting of imperfectly covered and unused cesspools, which have become dangerous pitfalls. One fatal accident of the kind at Woolwich has been the signal for others less serious, but sufficiently disquieting, and for a general probing of suspicious holes in gardens with clothes-props and other similar domestic implements. The result has been, we read, that a large number of communications have been addressed to the parish authorities all over the metropolitan district, from which it is inferred that London is honeycombed with secret wells and cesspools, covered, but left insecurely protected, since the completion of the main drainage, and of which the brickwork and the foundations are rotting and giving way. Here is a piece of work for the Metropolitan Board of Works—when its autumnal holiday is over. Meantime, we hope that insecure well-covers and rotting brickwork will be kind enough not to "give way". Our metropolitan, no less than our imperial legislators, require an autumnal relaxation; and we must trust to the civic and suburban cesspools to show in the interim a proper firmness.

#### SOMETHING ROTTEN.

THE doctrine *Qui facit per alium, facit per se*, is most properly applied to those offenders on a large scale who vend wholesale poison for the million at a temptingly low price, in the shape of rotten fruit, which costermongers try to retail to the poor. It is no moral excuse that the fruit is openly sold to the costermongers as damaged, and at so low a price as one hundred and five melons for fifteen pence. These said melons, fair to the eye, but utterly putrid and quite unfit for food, were subsequently, in the case which came under notice last week at the Mansion House, vended in the street at a shilling a-piece. The "openness" with which the damaged and putrid fruit was sold by auction was rather an imputation on the sanitary inspector of the City, whose information seems to be sadly at fault on the subject, than an excuse for the sale. One might have thought that the notorious fact that the sale by itinerant vendors of damaged fruit in the streets, as a source of danger especially to be guarded against in seasons such as this, would have turned the attention of the inspectors to the sources of supply. They seemed, however, to have been singularly inert; and it is to the public spirit and intelligence of a merchant named Pagnani that we are now indebted. The costermonger, Henry McDowell, who was arrested for selling the putrid melons, was with difficulty restrained from offering himself a sacrifice to his disbelief in septicity. At the last, he still wished to eat some of his own rotten fruit. If the auctioneers would make the same offer, and the inspector were induced to share the choleraic feast, a severe form of justice would be dealt out. But pomological suicide is not within the permitted punishments of the

English law; and, as the costermonger was not allowed to satisfy his sense of honour and carry out his east-end notions of the *kari-kari*, moderate fines or judicious reprimands will probably satisfy the further ends of justice; and we can only wish the inspector a "happy despatch" in preventing the further distribution of rotten fruit, purchased at prime sources at a nominal cost; and to this same end we call the attention of officers of health and their depending inspectors throughout the country.

#### DEATH OF A DOUBLE-HEADED CHILD.

WE read in the *Boston Herald* that this remarkable phenomenon, which arrived in this city a few days previously and was shortly to have been exhibited to the public, died on July 19th. The child, a girl, had two heads, four arms, and two legs, upon a single body; and the two portions of the body were so intimately connected that the death of one rendered that of the other inevitable. The child had enjoyed excellent health from her birth, nine months ago, until within two weeks, at which time one-half exhibited signs of illness. This, however, was but temporary. It recovered and was bright and playful. Soon after reaching Boston, the other half was taken sick, and died at five o'clock in the afternoon, the other surviving until eight o'clock in the evening. The spectacle is described as "strange and unparalleled." Upon one end of the body reposed the head of the dead infant; upon the other that of the live one with its eyes still bright and curious and its lungs in full breathing order. All that medical aid could accomplish was done, but it was found unavailing. The child died in the presence of its parents. The corpse presented the appearance of two infants asleep. Apparently they escaped the ordinary suffering incident to death, for the countenances had the expression of repose. Several physicians were desirous of having the body examined, but it was doubtful whether the parents would consent. They reside in Monroe county, Ohio, and carry on a farm. They have other children, although none of these have exhibited any unusual development."

#### SAFETY FOR SEASIDE-BATHERS.

THE terribly frequent and fatal accidents attending sea-bathing this year ought not to pass without a serious effort to arrest so distressing a loss of life in the future. We cannot think that all is done that ought to be done for the security of bathers when a rickety tub on wheels is pushed down to the edge of the surf, and inexperienced bathers are left to the mercy of the undertow and to the accidental exploration of deep pools or dangerous currents. Granting that most of these accidents are due to rashness or inexperience of the bathers, measures ought to be taken by the local authorities to save bathers from the fatal consequences of error in enjoying the healthful exercise which tempts thousands to the seaside towns, and in many instances constitutes the chief sources of prosperity to those towns. We believe that the local authorities of these towns would find it a proper and useful advertisement, if they could announce that one or more boats were stationed off the bathing-places, with proper means of rendering assistance, if required by accident; and in every place full directions should be prominently posted at the bathing-stations, warning bathers, experienced and inexperienced, of the precautions useful to adopt, the course proper to pursue, and the special sources of accident to be avoided. Such a boat and such directions are always to be found on the *Serpentine* during bathing hours, and have been the means of saving many lives which would otherwise have been sacrificed.

#### ENGLISH QUARANTINE.

It is of very little use stopping ships and disinfecting their holds, if the crews and passengers cannot be prevented from landing and disseminating whatever contagion germs they may happen to bring with them. At the meeting of the *Liverpool Health Committee*, it was a subject of complaint that no local authority had such power. The Committee had to consider on Friday a communication from the Government, reminding them that in 1866 cholera was introduced through foreign immigrants into Hull and other eastern ports, and asking them to

guard against such importation under present circumstances. They have replied to the Privy Council by alleging that no power exists in any local authority to restrain immigrants from going about the town, or to detain them in quarantine on suspicion of cholera or choleraic diarrhoea. In the recent evidence given by the Medical Officer of the Privy Council before the Royal Sanitary Commission, it was expressly stated that quarantine was simply a political and commercial expedient, intended to meet the prejudices of other foreign trading ports, and was not so organised as to have any sanitary or preventive value for this country. Under present circumstances, it is not without interest to know whether English quarantine is still a purely commercial expedient, as then described by Mr. Taylor, Mr. Helps, and Mr. Simon; and to ascertain whether it is hygienically a reality on which we can in any degree depend, or a sham by which we must not allow ourselves to be blinded. Our present information as well as past experience points in the latter direction.

#### PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.

THIS hospital had a narrow escape of being burnt down on Thursday of last week. By the efforts of the troops and borough fireman, the flames were fortunately confined to the laundry of the building.

#### A SENSIBLE RECOMMENDATION.

AT an inquest at Upper Norwood, touching the death of John Burman Messenger, aged nearly eight years, who died from drinking vitriol out of a ginger-beer bottle, the coroner said he thought some Act of Parliament should be introduced in order to prevent chemists from supplying deadly poisons without labelling the bottles, so that even the attention of the youngest might be called to the fact. He was sorry to say that several cases of neglect in such matters had lately come under his notice, and he trusted that the next session of Parliament would be productive of a Bill specially framed to meet the case. The jury recommended that some steps should be speedily taken to prevent the sale of deadly poisons in unlabelled bottles.

#### SANITARY REGULATIONS IN THE CITY OF LONDON.

THE City Commissioners of Sewers, with other public bodies, have been asked to assist the Government officials in their endeavours to prevent, if possible, the introduction of cholera into London; and there is reason to believe that some new and stringent regulations, especially with regard to shipping, will shortly be made and publicly notified by the Privy Council. In the meantime, the City Commissioners have, by a widely circulated notice, drawn the attention of inhabitants and owners of houses within the City to the various legal provisions made with a view to prevent nuisances, and consequently disease. It may not be uninteresting to give some of the more important of these provisions, premising that the dustmen in the employment of the Commissioners have been instructed to call at every house at least twice a week to remove dust, rubbish, and refuse of all kinds; and daily to clear out all public dust-bins, and cart away the contents. Any owner or occupier allowing stagnant water to remain, or the water-closet to overflow, is liable to a penalty of £2; and penalties may also be imposed upon persons either neglecting the sanitary orders of the Commission, refusing to discontinue any noisome trade after notice to do so, permitting common nuisances in houses, or keeping live cattle in cellars. Butchers or others are liable to a fine of £20 for exposing diseased meat, fruit, fish, or other provisions; and the same may be seized and destroyed. The Commissioners recommend families freely to use chloride of lime and carbolic powder in their houses, and request that every where the utmost cleanliness should be observed in respect of the condition of areas, basements, cellars, kitchens, and all damp and dark places. They also warn people not to allow the accumulation of rubbish, and to be careful as to the state of their water-butts and cisterns. They add that it is not only necessary that the inspectors should diligently perform their duties, but also that the owners and keepers of houses should be more than ordinarily careful in the management of their property.

## SMALL-POX IN SANTA CRUZ.

THE above town is just now entering upon a condition from which we in this country are just emerging; viz., an epidemic of small-pox. We have not many particulars of the matter, but it is reported that small-pox has been for some little time prevalent in Santa Cruz, though we cannot say for certain that it has yet assumed an epidemic form. There is one thing, however, quite certain, and that is, if the vaccination is not promptly and properly looked after, the ravages of this disease will be very great.

## IMPROVED WATER-SUPPLY.

THE Grand Junction Water Company have offered, through Dr. Lankester, the Medical officer of St. James's parish, to supply standpipes at all courts, lanes, alleys, and places where imperfect water storage is provided, and to provide an extra supply of water for flushing. The inhabitants will thus be enabled to draw the water especially for drinking and cooking purposes directly from the Company's mains, instead of the common receptacles, which are likely to be tainted. This is a timely and excellent offer. The Company will bear the expense, and their example deserves to be noted and followed.

## THE HEALTH OF MINERS.

AT the last annual meeting of the Royal Cornwall Institution, a paper was read on "The comparative health and longevity of Cornish miners", by Mr. Robert Blee. In 1847 the Royal Cornwall Polytechnic Society published in its fifteenth report a paper on the health and longevity of the mining and other populations of the Redruth Union. The tables accompanying that paper bore evidence of the great extent to which the health of the mining population had been affected during a period then not long preceding, by the labours in which they had been engaged. In the quarter of a century which had nearly expired since that paper was written, much good had been done by the society, and by isolated companies of adventurers, in the hope of lessening the dangers of the miners' occupation. Mr. Blee had directed inquiry mainly to three points, as in the paper read in 1847, viz., the proportions in which miners died at different ages, the diseases of which they died, and the comparative number of fatal accidents which had occurred among them, taking the four principal mining parishes in the union—viz., Redruth and Illogan, Camborne and Gwennap—for a period of ten years from January 1860. On the whole, the children of miners did not show a rate of mortality very different from those of other classes. In Redruth and Illogan, the infant children of miners died in somewhat larger proportions, while in Camborne and Gwennap the difference was in favour of the miner. Miners of feeble frame or peculiar susceptibility to disease very early succumbed to the fatal influence of their occupation. Twenty-eight per cent. of the miners registered had died between the ages of 10 and 30 years of age, and of non-miners only 13 per cent. had died between those ages. Between the ages of 40 and 60 years, the difference was largely increased, miners dying at that period in the proportion of 36 per cent., while for other males the proportion was only 20 per cent. Miners living to the age of 70 were 9.07 per cent.; men of other occupation, 31.06 per cent. In the two periods 1847 and 1871, it was shown that, whilst up to 50 years of age fewer miners now died than died twenty-five years ago, now many more died at more advanced ages. He concluded that much of the improvement in the working classes was due to the increase of wages, and the lessened price of bread and other necessities of life. Miners died in immensely larger proportions from disease of the chest than other classes, namely, 49 per cent. against 27 per cent.; and the protection from this cause of death, most imperatively required, seemed to be efficient ventilation, improved modes of ascent from the depths of the mine, and careful protection from the great and sudden changes of temperature. It was shown that out of those who were accidentally killed, 70 per cent. were under 29 years of age, and one-half of these were youths 13 to 19 years old. It was a question whether miners were sufficiently remunerated for the perpetual risk of life and limb they encountered; but that could only be satisfac-

torily determined by more minute investigation than was generally given it. The manner in which miners were paid was chargeable with much of the disadvantage to health under which the men earned their bread. A man, on commencing work, had to labour two months before being entitled to any pay. He was thus often compelled to purchase his goods for those two months, and too generally in perpetuity afterwards, on credit. He condemned the practice of paying men together in bank-notes, which caused them to adjourn to a public-house to change the money, and thus were tempted to spend it. While thanking the Royal Cornwall Polytechnic Society for what they had done for the advantage of the working miner, he begged them not to think that they had already done all that might be done for his benefit, and asked them to continue their exertions on his behalf. In the discussion which followed, Mr. Hill said the adventurers were always desirous of doing full justice to the miners; and if this was alleged to be not so, perhaps they would get some of those scenes which had disgraced the north of England. He spoke very highly of the conduct of the Cornish miners now as compared with years ago. Mr. C. Fox said the last return showed that there was a death every other day from the mode in which the men were raised from the pits. Captain James, as a miner, spoke highly of the miners' position now, and denied that they were dissatisfied. The President praised the conduct of the Cornish miner. They should be careful to invite in no way the Legislature to interfere in what was unnecessary, and in what was not absolutely required, at the expense of the adventurers.

## WHOLESALE VACCINATION-PROSECUTIONS AT BRIDGWATER.

LAST week there were fourteen vaccination-prosecutions brought before the county magistrates at Bridgwater. The authorities very wisely had selected a case, as an example, from each of the neighbouring parishes, so that the large district of Bridgwater was represented, so far as the unvaccinated are concerned, at the bar of the petty sessions in the borough town on Thursday last. Out of the fourteen cases, eight were condemned in costs, and two in fines and costs (the former were six-pence each); five were dismissed, and one was adjourned. The effect of the summons was to stir up the parents or guardians of the children to get them vaccinated before the summons became returnable. By so doing, they saved the fine, and only had to pay the costs. The three cases that were dismissed were those in which the medical officers were proved not to have given certificates, although the children had been vaccinated. The clerk thought that these gentlemen should be made to pay the costs. A person in court made the sensible remark, that a child is not *legally vaccinated* until a certificate has been given that it has been so successfully. There have been twelve deaths from small-pox, according to the last quarterly returns. The guardians are still haggling about the expenses of a separate hospital, and are pursuing a policy which has been from the first the cause of the extension of the epidemic into the neighbouring parishes. In case of the invasion of an epidemic, would it not be practicable to pitch a tent as a temporary hospital until a more durable structure could be secured or erected? In case of a hostile invasion of another kind, the volunteers would have to practise this kind of drill. During a severe epidemic of jail-fever which broke out two hundred years ago in Bridgwater, those not attacked encamped on the neighbouring hills for many weeks, not returning until the bill of health was clean in the town.

## EPIDEMIOLOGY OF SMALL-POX.

DR. DE RENZY states that in the Punjab, where small-pox is always raging, and slays its victims in thousands, our mortuary statistics show that the mortality from it begins to decline every year in June, the decrease in the number of deaths being steadily progressive in July and August. In the month of September or early in October the disease reaches its *minimum* of destructiveness. The deaths show a marked increase in November, and the increase continues, but somewhat unsteadily, in the succeeding months up to the end of May or beginning of June, when, as already stated, it attains its *maximum*. The cause of the fluctuation is altogether unknown.

## THE MIDDLESEX HOSPITAL.

MR. GEORGE LAWSON has been appointed Extra Surgeon to the Middlesex Hospital; and Mr. Henry Morris to the office of Assistant-Surgeon, rendered vacant by the resignation of Mr. Henry Arnott. By Mr. Lawson's promotion, a vacancy as Assistant-Surgeon will occur.

## PROSECUTIONS UNDER THE VACCINATION ACT.

A MAN named Tarr has been brought before the magistrates at Manchester, charged with neglecting to have his child vaccinated. He alleged that one of his children had been poisoned through vaccination, and he refused to become a party to "murdering" the other. The magistrate declined to discuss the wisdom of the law, but adjourned the case for evidence as to whether the child was in a fit state for vaccination.—Mr. John Pickering, a town councillor of Leeds, and a member of the Board of Guardians of the Leeds Union, was summoned before the magistrates sitting at the Town Hall on Monday last, for not having had his child, who was born on December 11th, 1869, vaccinated. He was ordered to have the operation performed within fourteen days. He had previously been fined three times.

## THE CORONERS OF MIDDLESEX.

THE Home Secretary has lately forwarded to the Middlesex magistrates an instrument under his hand, fixing the salary of Mr. Bedford, the coroner for Westminster, at £474:6:2 per annum. The Chairman said the amount fixed was that recommended by the justices. The Accounts and General Purposes Committees submitted a report showing the expenses which the coroners had incurred between the 1st of July and the 12th ult., and recommending that the charges made be paid. Captain F. B. Morley moved the adoption of the report, and pointed out that, whereas Mr. Humphry held twenty-nine inquests more than Dr. Lankester, his expenses were less by £69:15:6. However, by law the magistrates had no option but to pay the money. The motion was agreed to.

## ADVICE TO ST. PANCRAS.

A PERVERSE fate affords some of the St. Pancras guardians only too many opportunities to commit themselves. They are clearly unfortunate in their selection of officers, and, with whatever good intentions, unable to keep order or discipline in their establishment, or to procure satisfactory treatment of the inmates. According to the evidence before the coroner, the nurses employed are neither sober, trustworthy, nor attentive to the sick. They give medicines that are not ordered, and contrive to convert a paralytic old man into a gasometer by untimely chemical decomposition of chalk in his intestines; put on mustard poultices on Thursday when they are ordered for Wednesday; fail to make their rounds in the wards; are found at night, "not sober," in an easy chair, when they ought to be attending to ailing patients; and, while the patients are suffering from this neglect, and waiting for the inebriate night-nurse, they are enlivened by the screams of Mrs. Macintyre when beaten by her husband, the casual ward porter, at two o'clock in the morning. It is satisfactory to find that the porter was "admonished"; but it is by no means reassuring to learn that the chief anxiety of one guardian was as to the preservation of nurses reported for neglect, inebriety, crazy conduct, and ribald conduct. Nor is it at all surprising that the General Purposes Committee is unable to control and regulate properly this large establishment, when we find its chairman sitting officially at the Board, so little able to command himself as to allow himself to provoke by shocking insult an officer giving evidence, and to employ epithets as gross as "liar" and "coward". It is unnecessary to say that the circumstances disclose not the faintest justification for such charges but rather the contrary; for, whatever were the provocation, the employment of such language by a person sitting in an official capacity at a public board can on no grounds be defended. We heartily trust that, for its own sake, the General Purposes Committee will require its chairman either to offer a most ample apology for his disgraceful conduct, or compel him to withdraw from a

position which such breaches of propriety degrade and scandalise. We have the cause of local self-government too much at heart not to grieve sincerely at such evidences of incapacity and want of decency. They tend seriously to compromise the promise and usefulness of institutions which every Englishman must desire to see purified, elevated, and extended. The better part of the guardians of St. Pancras assuredly cannot be insensible to the degradation which such conduct as this brings upon every man belonging to the Board. It is for them to insist upon reparation. Meantime we venture to advise Dr. Ellis not to yield to the irritation of provocations, but to pursue an uniformly conciliatory though firm course, calculated to make the guardians respect him and themselves.

## STATISTICS OF OPERATIONS.

MESSRS. WALTER WHITEHEAD and S. M. Bradley of Manchester are at present engaged in a statistical work of some magnitude and importance. They are occupied in collating statistics of British surgery; and it is their purpose to issue returns every year of all the operations, including obstetric and ophthalmic surgery, performed in the public medical charities of the British Empire. An endeavour is also being made to secure returns from some foreign sources—Paris, St. Petersburg, Vienna, Berlin, and a few American hospitals, so as to draw a comparison between the results of surgery in different countries. It is also intended to obtain meteorological charts, and trace the connexion, if such exist, between vicissitudes of temperature and barometrical pressure with the death-rate. Comparisons will also be made between the results obtained in town and country hospital practice. The labour of collecting and analysing such statistics will be considerable; but, if successfully carried out, it will obviously be very valuable; and it is to be hoped that the work on which they are engaged will not be hampered by any want of response on the part of the authorities to whom they apply for returns. They purpose issuing blank forms, with full particulars of the nature of the returns which they require, to every public charity throughout the kingdom; and hope to publish the collated results on the 1st of May in each year. The first contribution will appear in the forthcoming number of the *Manchester Medical and Surgical Reports*, of which these gentlemen are the editors.

## A REMARKABLE CASE.

UNDER this title the *Times* publishes the following.

A very peculiar case, which has baffled several doctors, and which in a strange manner shows how life can be prolonged without anything in the shape of ordinary nutrition, has just come to light at a place near Preston. In the fold of Ennell-lane, which closely adjoins the village of Walton-le-Dale, and which is about a mile and a half from Preston, there is a cottage wherein for three years a young woman has been lying bedridden, and for between one and two years has had nothing to eat. Her name is Ann Riding; she is thirty-three years of age, and resides with her aunt. Prior to being taken ill, she was a strong, healthy young woman, never losing a day's work, and was employed as an operative at the mill of Messrs. Horrocks, Miller, and Co., Preston. Shortly after sickness set in she left work, was compelled to take to her bed, was medically attended, and for three years has been gradually sinking. Several doctors have at times attended her, but none of them have been able to give her any substantial relief; and six months ago remedial operations were abandoned, and the case left to itself, the idea of the aunt being that the "Almighty had to do with it", and that it was useless continuing to incur expense for medicines without any hope of a cure. For sixteen months the young woman has had no food at all, the only thing she could bear being a drop of water with which to moisten her lips. She is frequently asked if she will not have food, but always refuses it: she had no desire for it, and how she has for such a long period existed without anything possessing the least affinity to meat is a mystery. She is conscious, but very weak, gets a little sleep, and cannot bear a lighted candle in the room at night-time. It is supposed that she is suffering from abdominal atrophy; but the exact nature of the case is not positively understood, and it puzzles every one who is made acquainted with it, and especially when it is recollected that for a year and four months she has not had as much meat and drink as would have been requisite to sustain an infant a single day. The relatives in charge of the young woman are humble, honest people, and make no "show" of the case, which is hardly known in the district.

## A CORONER'S PRECEPTS.

IN a recent and most distressing case of child-murder, the coroner held an inquest, and, on his own authority, ordered a medical examination of all the women who lived in the house where the crime most probably occurred. All were to be examined, though the state of one only could give ground for suspicion. A writer, who justly comments upon this extraordinary proceeding, observes that he found, however, two medical men to carry out his precepts, which seems rather extraordinary; the police also helped him by bringing back to the house a person not in regular custody. The coroner's ready mode might be an effectual one, but it was such as no man in this country had legal power to use. The medical gentlemen, no doubt, believed the coroner's precepts to be peremptory, but in obeying them they were from first to last placed in a most distressingly false and painful position.

## THE REGISTRAR-GENERAL'S CHOLERA-PRESCRIPTION.

THE Registrar-General's last weekly return of births and deaths has appended to it some remarks on the treatment of cholera more startling than trustworthy. The Registrar-General, not content with advising that in all cases treatment should be applied early, informs the public that his own opinion is in favour of a repressive or astringent treatment of diarrhoea, notwithstanding his admission that in medicine various theories prevail, and that cathartics have been commended by some eminent physicians. So long, however, as eminent physicians differ upon this important practical question, the Registrar-General might advisedly abstain from attempting to cut the knot by an authoritative expression of opinion. The incompetence of this great statistical authority to deal with a purely medical question is shown by the following statement in his report with reference to the choleraic discharges. He says: "The serum escapes with great velocity, and, when once out, is as difficult to replace as the blood from a bleeding wound." Now, it is perfectly well known that the ordinary choleraic discharges, so far from consisting of blood-serum, which is a highly albuminous fluid, are composed mainly of water, with a very small proportion of organic matter. Thus an erroneous statement as to the character of the discharges and their resemblance to loss of blood is actually made the means of terrifying the public into the adoption of a mode of treatment which some high-authorities believe to be highly injurious, inasmuch as repressive drugs retain within the system the poisonous sewage-materials with which the air and the water, and even the patient's blood, are known to be contaminated. Among those who differ from the Registrar-General is a pathologist and physician of perhaps equal authority, whose views we recently solicited, and obtained the opportunity of placing before our readers—Sir Thomas Watson. The hundreds of parents who are weekly losing their children from diarrhoea will derive small comfort from being told by the Registrar-General that they have lost them "chiefly because the cases are not treated in their early stages". The tendency of this official statement will be to bring unmerited discredit upon those medical men who, having been called in early, have failed to cure their patients. If this great statistician were a practising physician, he would know, from painful experience, that no cases are more difficult to treat successfully than cases of infantile diarrhoea in large towns. The disease is excited and perpetuated by the breathing of impure air, and in the majority of cases a cure can be effected only by removing the patient from the poisonous atmosphere of the town to the purer air of the country. A natural result of the Registrar-General pronouncing dogmatically upon medical questions, and prescribing what, upon most insufficient evidence, he believes to be a valuable preventive drink, is, that one of his readers publicly requests "that a receipt for some simple and trustworthy remedy should emanate from the same source, and be published." This writer evidently believes that the Registrar-General is a high practical medical authority, which, with all due respect to him and his most useful office, we venture to say he is not. If any authority can properly be asked to make public recommendations as to treatment, it would be the Royal College of Physicians. In

1866, a Committee of the College was requested by the President to undertake this duty. They took much trouble about their anxious and responsible task, and felt much greater difficulty in carrying it out than the Registrar-General finds. Their report was a compromise, evidencing a deep distrust of cut and dried prescriptions such as are now being issued from Somerset House.

## FEMALE MEDICAL STUDENTS.

MEDICAL pursuits appear by no means to indispose the female mind to matrimony, or to terrify wooers. One of the *septem contra Edinam* is about to better the example of her metropolitan leader, and will be shortly married, while still a student of medicine.

## THE NEW METROPOLIS WATER ACT.

THE object of the statute lately issued is to make further provision for securing to the metropolis a constant supply of pure and wholesome water. It is with the recited Act (15 and 16 Vic., c. 84) to be construed as one Act. "From and after the passing of this Act (Aug. 21), every company shall on Sundays, as on other days, supply sufficient pure and wholesome water for the domestic use of the inhabitants within their water-limits." After eight months from the passing of the Act, every company, when required so to do in the manner directed, is to provide and keep throughout its water-limits a constant supply of water for domestic purposes, and make such water reach the top storey. After six months from the passing, the metropolitan authority may make application for a constant supply within such district; and, when not provided, an appeal is given to the Board of Trade. There are various regulations set forth in the statute, which is to be published; and penalties are to be recovered for non-compliance. The companies may require owners and occupiers to provide proper "fittings", which term includes communication-pipes, and also all pipes, cocks, cisterns, etc., used or intended for supply of water by a company to a consumer, and for that purpose placed in or about the premises of the consumer. Power is given to enter premises for the inspection and repair of the fittings. There are provisions as to fire-plugs. The Board of Trade may appoint persons to inquire and report on the quality of the water. It is an imperfect measure; and, even in passing it, the Government have expressed their sense of its imperfection, and their desire for its further amendment next year. Lord Shaftesbury considers it as just better than nothing; and the Metropolitan Board of Works, fearing it may stop further legislation, as possibly worse than nothing.

## SCOTLAND.

By a munificent donation of £1,000 from Mr. R. B. Stewart, of Ascog Hall, and other money, a hospital is to be erected for Rothesay.

WE regret to announce the death of Mr. William Flockhart, of the eminent firm of chemists, Duncan, Flockhart, and Co., Edinburgh. Although not a member of the medical profession, Mr. Flockhart was intimately acquainted with the leading medical men in Edinburgh, and afforded frequent and valuable assistance in many ways to those labouring in pharmaceutical and therapeutical science.

## ST. KILDA.

THE great infant mortality of St. Kilda has been the subject of continued correspondence in the *Times*. With regard to the hoarding of manure, one correspondent alludes to a village, nearly a mile in length, of which almost every house consists of but one room without window or chimney, in which at night are collected the whole family, together with their sheep, poultry, cow, and pony, if they possess as much. All the droppings and refuse are swept together during a great part of the year into one large heap at an end of the hut, and only cleared out for manure when the plot of ground is sown or planted. Yet in this village there is a population of healthy and hardy men, equal in strength and stature

to any he is acquainted with in the British Isles. He adds: "I should therefore attribute the mortality to other causes, but principally to the continual intermarrying of a population already closely related, who have little or no communication with the outer world." Another correspondent states as the result of his inquiries that about ten days after birth the jaws begin to relax, the lower one soon sinking quite powerless, and, through inability to suck, the baby wastes away in a few more days. Rear-Admiral Otter, who was in charge of the admiralty survey of the Hebrides, records it as his opinion that the infant mortality is due to the character of the mother's diet, which consists almost entirely of the oil of the fulmar, which gives to the inhabitants, he says, a peculiar odour, and renders the mothers' milk of a character unsuited to the child. As a proof of this, a child born during his stay thrived well, the mother being supplied with meat and other nutritious articles of diet.

#### ALLEGED FORCIBLE AND ILLEGAL CONFINEMENT IN A LUNATIC ASYLUM.

AN extraordinary account is published in the *Isle of Man Times* of the forcible confinement of a Manx gentleman in the Crichton Royal Institution, Dumfries. The certificate of lunacy is stated to have been signed by three medical men; but since his confinement has been discovered by his friends, he has been certified to be perfectly sane.

## IRELAND.

#### IRISH CORONERSHIPS.

THE coronership of one of the two districts into which Neath is divided has been vacant for three months. It is rumoured that there will be no appointment to the vacancy, but that the local magistrates will conduct the inquiries pending the introduction of a Bill abolishing altogether the office of coroner in Ireland.

#### SANITARY AFFAIRS IN DUBLIN.

MR. BENSON BAKER, who has been visiting Dublin on a doctor's holiday, and has been investigating its sanitary condition, has addressed a letter to the Dublin papers, in which he draws a gloomy, but, according to a public authority, not over-coloured, picture of the state of the city.

"No one passing through your streets," he says, "can fail not only to see, but to be informed by another sense, that excreta and decomposing vegetable and other refuse are producing 'excrement-reeking air'. No one can inspect the cellars and yards of the poor without seeing the danger to which they are exposed from excrement-sodden soil. The privies and cesspools baffle description; the top water percolates through a mass of filth into the cellars, and fills the house with 'excrement-reeking air'. Water-closets and dust-bins among this class are unknown. The Vartly water is exceptionally good and plentiful, affording, I am informed, twenty-five gallons per head *per diem*. This is the only satisfactory sanitary feature of the city; but even this is not utilised as it might be. It appears that more water than is used by the citizens is wasted in the bye-wash. This might with the greatest advantage be used for the purpose of watering the streets, flushing the sewers, and would go a long way in lessening the concentrated effluvia which arise from the Liffey at low water. As might be expected under these conditions, typhoid fever is endemic in Dublin, and at present is more fatal than typhus. Thirteen thousand of the citizens of Dublin suffer from fever annually, of which nine per cent. die. In a period of twenty-five years, every citizen of Dublin will have had fever; that is, the gross total of fever will equal the population, of which one in thirteen will die. The sanitary authorities have not supplied any mode of conveyance of infectious disease to the various hospitals. I know that public cabs and cars are frequently used to convey patients suffering from fever and small-pox. I myself saw a bad case of small-pox hawked on a cooper-monger's barrow through the streets of Dublin at one o'clock in the day, accompanied by several members of the family, to the hospital. It is at once evident that Dublin is specially prepared for the reception and multiplication of cholera germs. The precautions taken for the prevention of cholera are, I must say, unique. By order of the Privy Council, when cholera is discovered amongst the shipping, it is ordered to be brought on shore; there is no special provision made

for the conveyance on shore or to the hospital. Two hospitals have been appointed to receive these cases—one on the north, and the other on the south; thus establishing a cholera-focus on each side of the city. This danger might have been readily averted by obtaining a government ship and improvising a floating hospital."

Mr. Baker's statistical observations are not without flaw, and he does not give credit for the excellent arrangements by which small-pox has been kept at bay; but his strictures are well-intended; and, from what is known of his public character and ability, they are likely to be found based upon facts, and worth serious consideration.

## THE CHOLERA.

IN consequence of the cholera being reported in Antwerp, the Minister of the Interior issued (August 24th) an order subjecting all vessels coming from that port to quarantine.

#### PRECAUTIONS IN FRANCE AND ITALY.

FROM Marseilles, under date of August 23rd, we learn that in conformity with the International Sanitary Convention, Italy is taking precautions against the spread of cholera through ships arriving from the Sea of Azov and the Baltic. The Director-General of the Public Health Department, Dr. Fauvel, is visiting the French coast on the Mediterranean, ordering similar sanitary measures to be adopted. The public health in the South of France is very good.

#### THE CHOLERA IN PERSIA,

A CORRESPONDENT writes:—The cholera appeared in April at Bushire, left that town and slowly travelled up to Shiraz, where it arrived in May. There were only a very few fatal cases, and Shiraz, as well as the whole province, is now free of the epidemic. At Teheran it broke out in the beginning of May; at the end of that month nearly a hundred persons died of it daily, but at present it has almost disappeared.

#### CHOLERA IN RUSSIA AND GERMANY.

A BERLIN correspondent writes, under date of August 23rd, that the central and north-western portions of Russia continue to be ravaged by cholera. The provinces St. Petersburg, Moscow, Wilna, Riasan, Tambov, Pskov, Olonetz, Novgorod, Yaroslav, Vladimir, Nishni-Novgorod, Vologda, Kostroma, Kasan, Tver, Tulla, Smolensk, Saratov, Mohilev, and Suwalki, are officially stated to be infected. Moscow, Vladimir, and Suwalki—the latter, bordering on East Prussia, has spread the disease to German territory—are at present the districts most severely visited by the plague. Poland proper is as yet exempt. Reliable statistics as to the number of cases are wanting; but the vast extent of its area, together with what we hear, leads to the conclusion that the disease this time is not to be made light of. In Prussia, where the circles of Lyck, Pilkallen, Oletzko, and Insterburg, have been attacked, Königsberg remains the hotbed of the epidemic. In the seven days ending the 18th, that city had 130 deaths by cholera, among which were 51 children below the age of 14. The preceding week but one-third of this number had succumbed to the scourge. Since the last returns were published, there seems to have been an improvement. As a precautionary measure, the police authorities throughout Prussia have been directed by the Home Office to pay the strictest attention to the state of the sewers and cesspools, which have to be daily disinfected and deodorised, and frequently emptied. It will be a herculean task to cleanse the Augean stables of Berlin. Perhaps the Town Council, who have been so long wavering as to which system to choose, will now at last realise the necessity of selecting one among the various modern methods of drainage. The antiquated cesspools and sewers are simply an abomination. The sale of unripe or rotten fruit is prohibited. From St. Petersburg (August 25th) it is stated the cholera epidemic is considerably abating.

#### CHOLERA IN GERMANY.

DURING the week from the 18th to the 25th of August, 320 persons died at Königsberg from cholera. Among the number 127 were children. From the 27th to the 29th of August, there were 179 cases in Königsberg, with 79 deaths. At Elbing, up to Sunday last, there had been 34 cases with 20 deaths. The first case of cholera occurred at Altona on the 19th, and up to the 26th 16 persons died of the disease. From the 27th to the evening of the 28th no fresh case of cholera had occurred at Dantzig.

## PREPARATIONS FOR CHOLERA IN VIENNA.

ALTHOUGH there is no immediate fear of an outbreak of cholera in Austria, the following regulations have been issued for Vienna and the surrounding districts. 1. All physicians and surgeons are required to report immediately any cases of cholera that may come under their care. 2. The local authorities are to take in charge and continue regularly the systematic cleansing and disinfection of all house-drains and sewers. 3. Sanitary defects in individual houses are to be sought out and as far as possible removed. 4. The food-markets and the hawkers of articles of food are to be rigorously inspected. 5. Cholera-hospitals are to be established in Vienna and the neighbourhood; and patients suffering from the disease are not to be admitted into the general hospitals.

## CHOLERA-PRECAUTIONS: PROSECUTIONS OF PILOTS.

SEVERAL Burntisland pilots have been fined for rebelling against the local authority in bringing vessels into the harbour without allowing them first to be inspected by the quarantine officer.

## THE SEAMEN'S HOSPITAL SOCIETY.

THE Committee of the Seamen's Hospital Society, being desirous of making proper provision for any cases of cholera that may apply for admission into their institution, addressed the Lords of the Admiralty, requesting the loan of a part of the *Dreadnought* hospital-ship for the reception of such cases; but the Admiralty have replied that, as the ship is at present lent to the managers of the Metropolitan Asylums Board as a hospital for convalescent small-pox patients, their lordships are therefore unable to comply with the request.

## MORTALITY FROM DIARRHOEA IN LONDON.

THE deaths in London last week were 218 above the average, and the births 57 below it. The total deaths was 1682. They included 82 from small-pox and 487 from diarrhoea. The mean temperature last week, although showing a decline upon the previous week, exceeded the average on each day of the week. The fatal cases of diarrhoea, which in the two previous weeks had been 299 and 425, further increased to 487 last week; of these 450 were of infants aged under two years, and 21 of persons aged sixty years and upwards, leaving but 16 as occurring among children and adults aged two years and under sixty. These 487 deaths from diarrhoea in London exceeded by 295 the corrected average number in the corresponding week of the ten years 1861-70, and were equal to an annual death-rate of eight per 1000 persons living. The deaths referred to cholera and choleraic diarrhoea in London declined from 40 in the previous week to 28 last week. All who died were children, mostly infants, except three. The mean temperature of the air was 63.0 deg., or 2.4 deg. above the mean temperature of the corresponding week in fifty years. The highest day-temperature in the shade was 78.7 deg on Monday; the lowest night-temperature, 50.6 deg. on Sunday. The highest temperature in the sun was 146.1 deg., on Saturday.

## THE HAMPSTEAD SMALL-POX HOSPITAL.

MESSRS. WILLIAM GREAVES, Albert E. Kynaston, and John Aikman, Assistant Medical Officers of the Hampstead Small-pox Hospital, have thought fit to write to the *Times*, bringing grave charges against the management of the institution. The following facts, they say, have been brought to their notice.

Delirious patients, more particularly children, have been tied down to keep them in their beds, and this when their bodies were covered with the eruption which is peculiar to small-pox. Strait-waistcoats have been used with the same motive. Patients in an acute ward—that is, in a ward where the sufferers are still in the height of the disease—have been provided with a totally inadequate supply of milk and beef-tea for their use during the night. On making the morning visit, they have been informed by the nurse in charge that the patients of her ward on low diet have been kept without food of any kind from 7 A.M. till 3 P.M. Complaints have frequently been made to them by both nurses and patients that food supplied has been totally unfit for consumption. Children have been found dead in bed by the medical officer, and the nurse of the ward ignorant of the fact. This, it should be observed, was through the totally inadequate number of nurses provided for the necessities of the hospital, and not through the neglect of the individual on duty. The body of a patient who died at midnight being in the most offensive possible condition, was removed into the

bath-room of the ward, and there kept until the middle of the following day, instead of being at once carried to the dead-house. In addition to the above instances, one child, if not more, has been lost, and all trace of it gone, although at one time reported as convalescent. By continuous opposition and repeated complaints to the Medical Superintendent, they say, they have done some little good; but their task has been a most unthankful one, and has brought upon them no little odium, although one would have expected a contrary effect. The two senior of them have been informed that their services are no longer required; and thereupon the third has at once refused to remain, and has resigned.

We have personally inspected on several occasions the Hampstead Small-pox Hospital; and, since the appearance of the letter in the *Times* of Tuesday, have minutely inquired into the matters complained of. The result of these inquiries has led us to a conclusion very unfavourable to the assistant medical officers, and that the complaints made are mostly childish and exaggerated. That the arrangements of the hospital are incomplete in a few details is to be expected; but it is surprising to find an institution organised to meet a sudden and great emergency conducted with so great regularity and efficiency. If strait-waistcoats have in any instances been used, they were employed by and obtained at the special request of one of the gentlemen who now enter a protest against their use; if the food have been, under any exceptional circumstances, tainted or limited, the fault has been at once remedied on representation in the proper quarter; but the statements about patients being left without food for hours and found dead in bed are apparently inaccurate and most unfairly stated. There appears, however, to be good reason to believe that a child sent to the Convalescent Hospital at Islington has been missing; but how or when, the efforts of the Committee, assisted by the police during the past few weeks, have failed to discover. The matter is still being investigated; and in the meantime we would suggest that for a hospital at some distance from Hampstead, with one to two hundred patients, convalescents though they be, a resident medical officer might with advantage be procured.

With the single and strange exception, of a child being lost sight of in the process of removal, there is nothing to lead us to believe that the Hampstead Small-pox Hospital is otherwise than admirably conducted. We regret that the assistant medical officers should have deemed it necessary to write as they have done at all; but that they should have done so without laying their grounds of complaint before the Managing Committee was, we think, very unfair to the able and energetic medical superintendent, and unworthy of their position and of their responsibility to the institution. We are informed that a Poor-law inquiry will very probably be demanded by the Chairman of the Committee.

## SANITARY EXHIBITION.

THE Social Science Association have determined, at the request of many persons interested in sanitary reform, to hold an exhibition of sanitary appliances at their forthcoming annual congress, which is to be held at Leeds from the 4th to the 11th October next. Among the articles which it is intended to receive are: Filters, water-fittings, taps, standpipes and pumps; closet-apparatus; models and plans of improved workmen's dwellings; public baths and washhouses; gymnasiums; cottage and temporary hospitals; illustrations of various disinfecting processes; hospital-ambulances; illustration of drainage; farm, and sewage irrigation works; specimens of preserved meats and other dietetic articles; improved cooling apparatus, warming and ventilating apparatus, etc. The exhibition is intended to bring under the notice of health-officers and the many men interested and experienced in sanitary questions in various parts of the kingdom, who usually attend the congress, the latest appliances of science, having for their object the improvement of the public health, and will probably form an useful as well as an attractive feature of the meeting. Every information may be obtained on application to Dr. Robinson, Honorary Secretary of the Health Department, Social Science Offices, Leeds.

CROYDON GENERAL HOSPITAL.—An entertainment in aid of the funds of this hospital was given by the friendly societies in the town on the 16th instant. The net amount of contributions will, it is believed, amount to eighty guineas.

## THIRTY-NINTH ANNUAL MEETING

OF THE

## BRITISH MEDICAL ASSOCIATION.

*Held in PLYMOUTH, August 8th, 9th, 10th, and 11th, 1871.*

## PROCEEDINGS OF SECTIONS.—(Concluded.)

## SECTION D.—PUBLIC MEDICINE.

*The Training, Qualifications, and Duties of Nuisance Officers.* By DAVID DAVIES, Esq.—The writer said that a nuisance officer should be free from all organic disease; should have had the small-pox or been successfully vaccinated, and should have passed through scarlet-fever, measles, and maculate typhus. He should have good health, excellent digestive powers, and plenty of courage. The only literary qualifications required were an ability to speak the vernacular, and to enter in his book in intelligible language the chief facts which he observed. When such a man was found and appointed, he should not make himself disagreeable to everybody; but should act in the belief that his duty was to aid in lengthening the lives of those around him, without any consideration of the manner in which those lives were to be spent. The duties of a police-officer and of a nuisance-inspector were incompatible. He should be civil and courteous, should have the respect of the clergymen and ministers, should be friendly with the relieving officers, and should have the confidence and goodwill of the medical men. He should keep his eyes always open to what was going on, and report to the medical officers. He should have some idea of natural science; and should possess some acquaintance with the principles upon which zymotic diseases were propagated, and with their chief characteristics. The inspectors should be well-paid, so as to be able to live generously, and should not be required to do any menial work, but have two labourers under them. As an average, a district containing 20,000 was large enough; the nuisance-officer should be acquainted with the plan of its sewers and drains, and should go through it once a day; and twice a week disinfect all the privies in the courts and alleys.

*On the Modes of Dealing with Outbreaks of Pestilential Fevers sanctioned by the Health Authorities of Merthyr Tydfil.* By T. J. DYKE, F.R.C.S.—As medical officer of health since 1865, the writer had to direct the modes of dealing with outbreaks of cholera, typhus, and relapsing fever. Taking the acknowledged truism, that "contagious fevers spring from single cases", he argued that the early separation of the sick from the uninfected should prevent the spread of those diseases; and proceeded to instance the modes of dealing, based upon this argument, with the epidemic of cholera in 1866, of typhus in 1868-9, and of relapsing fever in 1870-71. These means were—the removal of the sick to hospitals provided for the purpose, and of the uninfected to places of temporary refuge; the fumigation of the houses with sulphur, and then the transfer of all clothing to a stove, in which it was exposed to a dry heat of 230 deg.; the washing of all walls down to the plastering; cleansing furniture with water and carbolic acid soap, and destroying all rags by fire; the free use of disinfectants in the houses, soaking soiled clothing in water containing disinfectants, and the addition thereof to all excretions. The results which seemed to follow this practice were, that cholera, which in 1849 destroyed 1 out of 30 of the people, in 1866 claimed but 1 victim out of 391. The annual mortality from typhus was formerly 23 in 10,000 living; in the years 1866-70, it was reduced to 8 per 10,000. The rate of deaths from relapsing fever was 2½ per 1000. After the adoption of the modes of removal, etc., the duration of cholera was but six weeks, while typhus and relapsing fevers yielded in two months. The town of Merthyr used to be exceedingly unhealthy. A good supply of pure water, regular scavenging, sewerage, etc., resulted in lessening the death-rate from 36 per 1000 in the years before 1850, to 24 per 1000 in 1866-70, while the average age at death was increased from 17½ to 27½ years. The imperfect working of the sanitary laws was pointed out; but it was stated that even these, with the "hearty good-will of the authorities", could be made of great use both in preparing for the advent and for the treatment of pestilence. In conclusion, instancing the fact that relapsing fever prevailed at Tredegar for two years, and yet that no public information had been given of this epidemic, he urged the necessity of a compulsory registration of cases of small-pox, of typhus and its congeners, and of cholera, as a means through which all sanitary authorities might be warned of the nearness of danger, and thus might be enabled to burnish and sharpen their sanitary armour.

*On the Provision of Medical Attendance on the Independent Poor by Provident Dispensaries.* By C. B. NANKIVELL, M.D.—The subjects treated of were the following:—The necessity of prompt and efficient medical attendance on the working poor; the defects of gratuitous medical charities and their demoralising consequences; the evils of sick clubs in beating down the terms of their medical attendants, and including persons able to pay for medical advice; the importance of the provident principle in dispensaries in raising early and efficient medical assistance within the means of the poor; their success at Coventry, Derby, Northampton, and other places—at Northampton receiving in one year from the working people £1,880, and paying the medical officers £1,500; the importance in establishing provident dispensaries of having a sufficient number of honorary subscribers to provide a body of governors and defray the expenses of the establishment above the cost of medicine and medical attendance; the number of officers to be in proportion to number of free members, and the advantages of such institutions in practical medical education.

*Jenner and his Teachings.* By J. G. DAVEY, M.D.—The paper was designed to prove, from the early writings of Jenner, that medical men of this day had failed to practise vaccination after the manner, or rather in the light, of the first great teacher of the art; that they had ignored the preliminaries to which he attached very much importance; and had fallen, therefore, out of the path along which Jenner travelled to reach the success which he realised. From the statements made by Dr. Davey, it followed, necessarily, that Jenner's practice was very much unlike that followed at this time, and that in both theory and practice the practitioners of the day must have fallen away from the teachings of the famous physician of Berkeley. If Jenner doubted (as it was affirmed he did) the virtue of the vaccine lymph after even "five generations"—that is, after its passage through but five persons or children successively—and if he "then thought it prudent, after only five gradations", to seek other and fresh lymph from the cow or heifer, it became our duty to ponder awhile over the very dissimilar views generally entertained, as well as on the practice which these views begot. But according to the Jennerian aspect of the whole question, we were led to believe that other and deeper causes for the altered or diluted and comparatively valueless quality of the vaccine lymph now so much in use existed. The teachings of Jenner prepared us to accept, as indispensable for the production of a pure, fresh, and trustworthy vaccine lymph, whereby to insure the safety of our patients from the viruluous contagion, the aid of the horse. The grease from his heel, taken before it had lost its early pellucidity, was, it was stated, the mainspring or starting-point of that virus on which Jenner relied to carry all those which he vaccinated secure from the possible invasion of small-pox through the period of their natural lives. The same grease it was, according to Jenner himself (so said Dr. Davey), which in its passage through the cow was converted into what is the only reliable antidote to small-pox.

*The Effect of Submarine Descent on Man, and the Limits of his Capability.* By THOMAS LITTLETON, M.B.—The paper contained extracts from a communication addressed by Dr. Littleton to the ASSOCIATION MEDICAL JOURNAL (now the BRITISH MEDICAL JOURNAL) in 1855, with confirmations of the pathological views therein maintained; and in addition some allusions were made to the history of diving operations connected with the port of Plymouth. He referred also to the effects of the sudden removal of atmospheric pressure in the exit of divers from the water, which he had opportunities of observing during the construction of the Royal Albert Bridge at Saltash. He also spoke of the muscular mechanism existing in the throat of the whale, by means of which the air-passage can be closed during descent in the water; and to the practice adopted by some divers of pressing an oiled sponge into the fauces. He believed that, with the means of imitating the conditions found in the whale, man would be able to descend to as great a depth as that animal.

*Sewage-Irrigation in connection with Public Health.* By WILLIAM HOPE, Esq., V.C.—The introduction of sewage-irrigation, Mr. Hope believed, would do more for the public health of England than almost any other reform which had yet been suggested. He undertook the advocacy of it from a sense of duty, because sewage-irrigation, or sewage utilisation in whatever form, was a problem which demanded not only the co-operation of chemists, engineers, and agriculturists, but the assistance and the jealous supervision of those members of the medical profession who more especially devoted their attention to questions of hygiene. There were proposals to deal with sewage in its liquid and solid forms separately. Indeed, many persons were enthusiastic enough to believe that the average British housemaid, or the average working man's wife, could be trained to carry out a duplicate system of slop-collection—the one for the reception of urine only, and the other for the

reception of dirty water of all kinds. The Rev. Mr. Moule talked about a small area of land for subterranean irrigation as an adjunct to this system; but such an area, intersected by porous pipes, through which the stuff had to percolate under pressure, was to be looked at simply as a series of small elongated leaking cess-pools, by which the subsoil would be kept continually saturated with unoxidised solutions of animal and vegetable matter containing vibrios, bacteria, and other suspicious organisms. Besides, this subterranean irrigation would necessarily pollute any springs or wells that might be within reach. Coming then to those systems which attempted to deal with town sewage, when manufactured by all the usual appliances of water-closets, sinks, drains, and sewers, Mr. Hope observed that, if some very perfect filter were discovered which would reduce the effluent water to the same physical state as that of freshly distilled water, it would probably open up a simple and completely successful plan of dealing with the sewage. But no such filter at present existed. After a passing reference to the desirability of excluding sewage from rivers whence human beings obtained their drinking water, he went on to point out that no chemical system of purification could be successful, and, therefore, set down irrigation as the only means of dealing with the sewage question in all its bearings with a fair chance of success. Irrigation had its dangers. In the opinion of some the germs of entozoic disease might be communicated, both through vegetables grown by sewage and eaten raw, such as lettuce, celery, etc., or through the flesh of oxen and sheep fed upon sewage-grown produce; but experiments conducted for a committee of the British Association had not established that view. He had heard Dr. Letheby allege that all sewage farms were pestilential swamps, and he believed that this description was accurate to a considerable extent, for sewage farms were laid out, as a rule, by civil engineers who had never condescended to study agriculture. The engineering works for the conveyance of sewage from the town into the country were only the means; the agricultural utilisation of the sewage was the end. The means must be subordinated to the end. The equal and uniform distribution of water over the surface of land by irrigation during the night was a problem of such extreme practical difficulty, that it was not too much to say that it was a thing which could not be done. Yet, as a rule, no provision was made for storing sewage at night. No farmer applied more manure to his crops than he thought they could consume. Nevertheless, because one hundred was an easy number to remember, it was the fashion amongst engineers to lay out only one acre to receive the sewage of every hundred persons; in other words, to decree that the plants upon that acre should consume a great superfluous quantity of nitrogen. All botanist farmers knew that the most valuable of cultivated plants would not flourish—sometimes not even grow—in “water-logged” land; but engineers in large practice would argue strongly against draining land which was to be irrigated with sewage. If sewage were run on in a dark night in quantities in excess of the requirements of plants, the necessary result was a swamp. It was erroneous to conclude, however, that all sewage farms must necessarily be swampy. The application of the sewage of 100 or 150 persons to every acre of a farm for an indefinite term of years was absurd. It was evident that the reduction from 100 or 150 to 20 or 30 persons per acre would relieve Dr. Letheby’s “pestilential swamp” of its bad character; and if the land when so relieved were treated according to the teachings of science and of practical agriculture, he was confident that the swampy and objectionable character of sewage-irrigated land would vanish altogether. One of the most important things to be derived from the use of sewage was the extra supply of food which might be obtained, and especially milk for the young. He believed that one, if not the principal, cause of the debility of the town population was the absence of pure milk for the use of children, and this also was one great cause of drunkenness in the old.

Mr. F. W. MOORE asked various questions as to the practical working of the utilisation scheme. He drew attention to the serious statement of Dr. Letheby that irrigated meadow-lands were liable to breed parasitic diseases in the animals which feed in those meadows, and he said he doubted whether the ova did overcome all the disturbance of passing from the sewage to the land, and really enter the animals.—The Mayor of Plymouth (Mr. SERPELL) desired information as to how Mr. Hope would proceed to drain towns, situated as Plymouth and Devonport were, in a hilly district.—Mr. LIDDLE referred to several localities where illness had arisen near places where sewage-irrigation was used. He considered this subject of sewage-irrigation a most important one, as in its practical working other matters of deep importance to the community were associated with it, such as the question of pure water and a larger supply of food, especially of milk.—Mr. BALKWILL said it would be well for Plymouth if it could utilise its sewage; for now it was casting it into the sea, to the nuisance of the neighbourhood. He thought that the proposal made elsewhere to have double sew-

age—one for sewage proper, and the other “slops,” etc.—so as to keep the two classes of material separate, would not be found practical.—Mr. DYKE referred to the attempt being made to utilise the sewage of Merthyr Tydfil. The whole matter had been thrown into chancery. The plan adopted at Merthyr, he said, was on the calculation that thirty acres of land would be sufficient for the sewage of 10,000 population.—Mr. HOOPER drew attention to the manner in which the sewage was carried out at Croydon, and said that it was so done as to leave a nasty smell.—Mr. HASTINGS said that for his part he did not need Mr. Hope’s paper to convince him of the necessity and value of utilising the sewage by irrigation. He had heard very able men discuss the question, and he had arrived at the opinion that irrigation supplied the best and the most economical means of disposing of the sewage of our towns. Water-conveyance was the cheapest incomparably, and the cost of conveying earth in large towns was one element against the use of earth-closets. The irrigation system increased the fertility of the soil, and this fact proved to him that it was sheer waste to go on throwing sewage into the sea. So long as the sewage was thrown into the sea, millions of money would be annually wasted which would otherwise have gone into the pockets of the people. There were disadvantages in connection with the utilisation; for at Malvern the people said that cases of fever in that district were the result of the irrigation. He had himself found a bad smell arising from sewage, and had known cases of fever near where the irrigating was carried out. He should like to ask Mr. Hope if he thought it likely that the fever referred to was likely to arise from the sewage.—Mr. MOORE asked if it was not possible to carry the sewage on to the land by means similar to those adopted for watering lands on a small scale.—The PRESIDENT (Dr. STEWART) added the results of his own observations at Ilford, where a sewage-farm was carried out on Mr. Hope’s plan. His nose was not at all offended by any smell. The farm at Ilford proved that where irrigation was carried out scientifically there was no fear, but where the water in daily use was polluted, local outbreaks of fever were to be expected. Now some local outbreaks of fever came in most healthy places, and there was scarcely any doubt but that there was a connection between the outbreaks of fever at Malvern and the sewage.—Mr. HOPE, in replying, said he never found a town yet in which it would not have been the cheapest plan to carry the sewage to some distance away before utilising it. The cost for a town of a given size could not be stated, for there were expenses which would be entailed in a small and a large town alike, as for purchase of rights of way, obtaining powers, and engineering. We were now arriving at a time when, thanks to the Court of Chancery interfering to prevent the pollution of rivers, towns would have to utilise their sewage, cost what it might. It was as dangerous to throw the sewage into the sea as into the rivers, for the ova passed into the fish of the coast, and so came back. He showed that the animals fed upon the meadows badly and unscientifically irrigated with the Edinburgh sewage, which, judging by its smell, was the foulest sewage in the world, were none the worse, and no parasitic ova were found in their flesh. As to the value set upon the sewage by the farmers who once tried it, he mentioned that some Essex farmers had eagerly set down their names as customers when there was a prospect of some of the sewage being supplied; and, in fact, he obtained in two days the name of 69 farmers who farmed 40,000 acres. The sewage caused fever where it was improperly conducted to the land, as at Malvern. The throwing the sewage on the land had been tried by Lord Essex at Watford, and proved a failure in point of paying, the cost of labour being very great. He would not enter into the probable cost of using the sewage of the three towns on the adjacent lands, because he was a stranger in the neighbourhood.

The MAYOR of PLYMOUTH proposed a cordial vote of thanks to Mr. Hope. Mr. PROWSE seconded the motion, which was carried amid cheers, and was acknowledged.

*A New Mode of Hospital Construction.* By HENRY GREENWAY, M.R.C.S.—The author proposed that a portion of a hospital building should consist of flats 34 feet wide and of any required length. The floor of the flat should be water-tight and covered with sheet-lead. Within the flat should be a double row of compartments made of glass with iron framework, and placed back to back; each compartment being 10 feet square, 12 feet high in front, and 17 feet at the back, thus causing an inclined ceiling. Between the front of these compartments and the main wall, which would be of masonry, there should be a corridor 7 feet wide, 12 feet high, its ceiling to be likewise of glass. Into this corridor these compartments should open. Each compartment should be ventilated by a tube passing through the masonry wall, and then across and underneath the corridor, and which should open in the floor of the compartment through the length of a grating. Around this tube would be a water appliance to cause a draught; but this would

not make patients catch cold. The corridors could be subdivided by means of glass-folding doors, so as to form anterooms for those patients who would be permitted to leave their compartments. The proper temperature would be maintained by means of water-pipes. The compartment would be illuminated at night by transmitting light from the corridor. At each end of the flat should be placed the usual ward offices. They would be separated from the compartments by a cross passage which would unite the two corridors. In cases of emergency the nurses could be called by signals. The cost of such a building for twenty-one beds and one flat had been estimated by an able Plymouth architect, Mr. Hine, as about £3,000, or £150 a bed. The following were some of the advantages gained by this plan. Each patient was in enjoyment of his own special supply of atmospheric air, not damaged by exhalations from his neighbour. The supply was also being constantly renewed; the compartment being made of glass, no absorption of morbid products could take place in their walls, and by occasionally washing them with water they would for ever retain their purity. There would be no danger on the score of fire; and as a patient lay in his bed he saw not only the transparencies, but could look through his glass door across the corridor at the little garden outside the window. He had also the advantage of a compartment to himself, thus avoiding the unpleasantness often felt on being associated with strangers; and he would not be shocked by death occurring around him. The patient, although plentifully supplied with air, was not exposed to a draught, the under surface of the bed acting as a screen. The patients were not confined to their beds, and having no infection, might be allowed to take their meals in the corridors during the day.

*On the Estimation of Atmospheric Ozone by means of Aspirators and Acids.* By CORNELIUS B. FOX, M.D.—The author, having pointed out the great importance of estimating correctly the amount of ozone present in the air, if we would ascertain with certainty whether or not an excess or deficiency of this allotropic modification of oxygen was in any way connected with disease, proceeded to comment on the chaotic and inexplicable condition in which all ozone records were involved. The mode of estimating ozone which had been hitherto generally adopted appeared to be liable to the following sources of error:—1. Impurity of chemicals employed; 2. Impurity of paper employed; 3. Ozonometers faulty in construction; 4. Formation of the iodate of potash; 5. Bleaching and fading of the coloured tests, (a) from formation of the iodate of potash, (b) from presence of true antozone in the air, (c) from volatilisation of the iodine set free, in consequence of (a) a rapid current of air, (b) an excess of moisture in the air, (c) a high temperature; 6. Changes in the force of the wind. Brodie and others considered Schönbein's antozone to be a myth, whilst some German savants had recently proved that it was simply the binoxide of hydrogen. Dr. C. Fox believed in the existence of an antithetical state of the air, and described both the atmospheric conditions under which it occurred and its effects. This principle he named *true antozone*, to distinguish it from Schönbein's antozone, with which it had hitherto been erroneously identified. The various errors above enumerated, of which the formation of the iodate of potash was one of the greatest, were then shown to be easily obviated. This colourless salt, into which much of the iodine set free by the ozone was often converted, he decomposed by the application to the tests of tartaric acid in the form of spray, so that the whole of the metalloid might be estimated. The error arising from the changes in the force of the wind was also avoided by the use of aspirators, by means of which a certain amount of air was made to pass over the tests at a certain velocity. The two forms of aspirators which had been employed for this purpose having been adverted to, a third kind of an improved construction, which had been devised and employed by Dr. Fox, was then described. The author considered that it was important to have correct answers to such questions as the following. Have an excess or deficiency of atmospheric ozone, or *true antozone*, any effect on the public health? If so, what is the nature of this influence? What is the effect of epidemics on their amount? He proposed that a Committee be appointed by the Association to inquire into the merits and feasibility of the new scheme.

*Notes on the Institutions for the Relief of the Sick, Wounded, and Disabled of the Royal Navy.* By WM. R. E. SMART, C.B., Inspector General Royal Navy.—The medical institutions are traceable to 1588, when, after the defeat of the Armada, the seamen gave a portion of their pay to rescue their maimed shipmates from destitution. This money being deposited in an iron chest kept in the church at Chatham, was distributed to claimants by officers selected annually from the various branches of the Navy. "The Chest of Chatham" was the only medical institution until Greenwich Hospital was founded by William and Mary. Then these institutions became interdependent, the one giving out-door pensions, and the other in-door maintenance, until the year 1763,

when their means being found insufficient to meet the great demand, the State began to pay out-door pensions to the disabled sailors. Until 1796, the Chatham Chest paid for the medicines and instruments of the Navy; and until 1812, when its funds were about to be thrown into those of Greenwich Hospital, the Chaplains received the best portion of their income from it. In 1869, the State obtained entire control of the united properties of the Chatham Chest and of Greenwich Hospital, yielding an income over £148,000 a year. The inmates of Greenwich Hospital were dislodged, and the out-pension system was extended; sick pensioners being permitted to enter the naval hospitals for treatment under rather close restrictions, which might be rendered less close than at present. The naval hospitals at Portsmouth and Plymouth were built between 1750-60, and their value to the service was at once manifested. These admired establishments reflected credit on the Admiralty, but there was ground to apprehend that in case of a naval war, those now maintained would be very inadequate, and it was desirable that Greenwich Hospital should be altered in readiness for such emergency. The general health of the navy had undergone constant improvement since 1790, and was at present in such a condition, apart from the casualties of seamen's life, as to inspire hope that, by the substitution of iron-clads for wooden hulls, the health-returns of the men in the navy might be soon brought on a par with those of Londoners of the same ages.

#### THE JOINT-COMMITTEE ON SANITARY LEGISLATION.

THE following resolution was passed at the concluding general meeting of the Association in Plymouth, on August 11th, after the reading of the report of the Joint-Committee on Sanitary Organisation.

Moved by GEORGE W. HASTINGS, Esq., seconded by JOHN LIDDLE, Esq.—

"That this meeting receive and adopt the report now submitted by the Joint-Committee of the British Medical and Social Science Associations, and reappoint, as the Committee of this Association, the following gentlemen, with power to add to their number:—Dr. J. T. Arlidge, Newcastle-under-Lyne; Dr. Edward Ballard, London; Dr. W. Budd, Clifton, Bristol; Dr. Burke, Dublin; Dr. Charlton, Newcastle-on-Tyne; David Davies, Esq., Bristol; Dr. Druiitt, London; T. J. Dyke, Esq., Merthyr Tydfil; Dr. Falconer, Bath; Dr. W. T. Gairdner, Glasgow; Ernest Hart, Esq., London; Dr. Heslop, Birmingham; Dr. Lankester, F.R.S., London; Dr. James Lewis, Maesteg; John Liddle, Esq., London; Dr. W. M'Ewen, Chester; Dr. Mapother, Dublin; Dr. J. E. Morgan, Manchester; Dr. G. H. Philipson, Newcastle-on-Tyne; Dr. Arthur Ransome, Bowden; Dr. Tindal Robertson, Nottingham; Dr. Joseph Rogers, London; Dr. Sieveking, London; T. Heckstall Smith, Esq.; St. Mary Cray; Dr. Strange, Worcester; Dr. W. S. Trench, Liverpool; Dr. Nicholas Tyacke, Chichester; Dr. Washbourn, Gloucester; Dr. A. T. H. Waters, Liverpool; Dr. Edward Wilson, Cheltenham; and Dr. A. P. Stewart, *Honorary Secretary*."

#### POOR-LAW MEDICAL REFORM COMMITTEE.

THE Poor-law Medical Reform Committee, reappointed at the meeting on August 11th, consists of the following members: Dr. Sibson, F.R.S.; Dr. Falconer; Dr. A. P. Stewart; Dr. Heslop, Birmingham; C. A. Newnham, Esq., Wolverhampton; A. Fleischmann, Esq., Cheltenham; T. Heckstall Smith, Esq., St. Mary Cray; Edwin Chadwick, Esq., C.B.; S. Corrance, Esq., M.P.; Dr. Beatty, Dublin; Dr. Macnamara, Dublin; Dr. Mapother, Dublin; Dr. Joseph Rogers; W. Fairlie Clarke, Esq.; Benson Baker, Esq.; Ernest Hart, Esq., Chairman and Convener; with power to add to their number.

### ASSOCIATION INTELLIGENCE.

#### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEDICAL MEETING.

THE next meeting of the members of the above District will be held at the Church Institute, Ramsgate, on Thursday, Sept. 14th, 1871, at 2 o'clock: JOSEPH AUSTEN, Esq., R.N., in the Chair.

Dinner will be provided at the Granville Hotel at a quarter to five o'clock precisely. Charge 5s., exclusive of wine.

All members of the South Eastern Branch are entitled to attend, and to introduce friends.

Gentlemen who wish to make communications to the meeting, are requested to inform me *at once*, in order that a notice thereof may be included in the circular convening the meeting.

CHARLES PARSONS, M.D., *Honorary Secretary*.

2, St. James's Street, Dover, August 1871.

## REPORTS OF SOCIETIES.

### MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

J. HUGHES BENNETT, M.D., F.R.S.E., in the Chair.

MR. LISTER showed a patient in whom, more than six years ago, he had Excised the left Wrist-joint. Excellent movement and strong grasping powers were shown, and the patient was able for all the duties of his employment, in charge of an engine.

MR. LISTER also showed a case of Cicatrix after a Burn binding the arm to the side, in process of cure. Movement was nearly restored. He showed the method at present used of antiseptic dressing by means of carbolised gauze and antiseptic bandages.

MR. LISTER exhibited a little boy on whom, some weeks ago, he performed primary Amputation at the Hip-joint for extensive injury of the leg. Antiseptic dressings were used, and, during the whole progress of the case, putrefaction had been completely prevented. The stump was soundly and completely healed.

MR. ANNANDALE showed a case of Club-foot in process of cure, and a case of Amputation of the Hand in which the thumb was retained.

DR. A. G. MILLER showed a specimen of Fracture of the Cervical Spine from a fall from a window.

DR. T. R. FRASER called the attention of the Society to a new Mineral Water of great value recently discovered at Melrose. It is a chalybeate, but is remarkable as containing the iron in the form of carbonate and in considerable quantity, and is the only one yet known in Scotland in which the iron is in this form. It is sparkling, pure, and pleasant in taste.

DR. ARGYLL ROBERTSON showed two Eyes which he had recently obtained. In one, the fatty degeneration of the retina in albuminuric retinitis was well seen; in the other, there was calcification of the choroid.

DR. WARBURTON BEGBIE read a paper on the Therapeutic Actions and Uses of Turpentine. He gave a brief sketch of the ancient history of the drug from the time of Hippocrates, with a notice of the various forms in which the oleo-resins of the coniferæ are used or have been used in therapeutics. Oil of turpentine was described as being irritant and stimulant, quickening the circulation and augmenting the temperature of the body. In larger doses it produces a sort of intoxication; in drachm doses it is hypnotic. Externally it is a valuable rubefacient, and is absorbed by the skin so as very soon to be recognised in the breath, and by its characteristic violaceous odour in the urine. The production of this violaceous odour in its perfection seems to be a test of the integrity of the urinary organs, as it is less marked or absent in disease of the kidneys. The therapeutic actions and uses of turpentine are various. 1. As a cathartic it is uncertain, but along with castor-oil it is useful in cases of obstinate obstruction and tympanitis. 2. As an anthelmintic it is chiefly used as a cure for tapeworm; also, in the form of enema it destroys ascarides and lumbrici. 3. Though turpentine sometimes causes hæmaturia, it cures certain passive hæmorrhages. It is useful in purpura, probably acting through the nervous system; and is useful also in hæmoptysis, hæmaturia, and uterine hæmorrhages. 4. As a stimulant, it is especially valuable in adynamic fevers; as in the stupor of typhus, in certain kinds of delirium, and in the later stages of enteric fever with a dry tongue. 5. In certain nervous diseases, such as epilepsy and chorea, it is said to be very useful; but in epilepsy it is supplanted by bromide of potassium, and in chorea by arsenic. In certain forms of sciatica and crural or brachial neuralgia in the aged, twenty-minim doses thrice daily have very good effect. In the nervous headache of delicate females, and the headache which is induced by fatigue, it is a better stimulant even than strong tea, and without the effect which tea so often has of banishing sleep. 6. In all chronic discharges from mucous membranes, such as chronic and fetid bronchitis, it is very useful, and even is advantageous in gangrene of the lung in checking the fœtor. Under this head some interesting cases were given of gangrene of lung depending on the presence of foreign bodies.—A discussion followed, in which the Chairman, Mr. B. Bell, Dr. T. R. Fraser, Mr. Lister, Dr. Smart, Dr. T. G. Stewart, and Dr. Joseph Bell took part. Additional evidence as to the value of turpentine in hæmorrhage and in chronic mucous discharges was elicited.

DR. WARBURTON BEGBIE communicated a very interesting paper by Dr. MICHAEL W. TAYLOR of Penrith, entitled Case of Intestinal Obstruction from a knot on the lower part of the Ileum. A cast, made and coloured by Dr. Taylor, accompanied the paper, and added greatly to its value.—The Society then adjourned for the season.

### SURGICAL SOCIETY OF IRELAND.

ALBERT J. WALSH, Esq., President, in the Chair.

MR. WILLIAM STOKES described a method of Amputation of the Thigh, to which he gave the name of Supracondyloid Amputation. In the amputation, the bone was sawn through at a level from one-half to three-quarters of an inch above the line of the cartilaginous incrustation, the cartilaginous surface of the patella was separated, and there were two flaps—one anterior, oval in shape; and one posterior, one-third of the length of the former. The posterior surface of the patella was brought into apposition with the cut surface of the femur, and underwent ankylosis with it. Mr. Stokes exhibited a series of casts showing the results obtained after this operation. Mr. Jessop of Leeds had likewise had a satisfactory recovery in a case where he had performed it. The special advantages to be derived from this method of amputation were described as being the following. 1. The resulting stump was more useful, as pressure could be borne on its extremity. 2. There was a diminished liability to tubular sequestra. 3. The operation was less hazardous to the patient than amputation of the thigh, its situation being more distant from the trunk. 4. It was accompanied by less shock. 5. There was less tendency to the occurrence of suppuration. 6. In the posterior surface of the anterior flap, which was lined with a natural synovial membrane, no vessels or nerves were included. 7. The preserved portion of the patella acted as an osseous curtain covering the cut surface of the femur, and had never yet been known to slough away. 8. That the attachment of the tendon of the quadriceps extensor muscle to the patella, gave an increased power of extending the thigh in progression, and rendered the formation of a conical stump impossible. 9. In the supracondyloid operation, the vessels were divided at right angles to their continuity, and not obliquely, as in all flap-operations, thus being less exposed to the setting up of inflammatory action from the extent of the wounds in them.—MR. H. G. CROLY considered that the operation would be contraindicated in diseases of the knee-joint, such as "white swelling." He asked whether the patella always remained healthy in its new position, or acted as a foreign body—an accident often met with in the case of the os calcis in Pirogoff's operation.—DR. WHARTON thought that the operation advocated by Mr. Stokes was to be contrasted with Mr. Syme's percondyloid amputation, and was not intended to supersede all other amputations of the thigh.—DR. PORTER looked upon the ankylosis of the patella with the cut end of the femur as a most important characteristic of Mr. Stokes's plan. It possessed another great advantage, in the avoidance of including the open ends of vessels in the anterior flap.—MR. WHITE had, by experiments on the dead subject, tested the height to which the operator might go without opening the medullary canal of the femur, and had found Mr. Stokes's estimate perfectly correct. He strongly commended the operation in cases which were unsuited either for resection of the knee-joint or for Teale's amputation of the thigh.—DR. HENRY KENNEDY wished to know the nature of the various cases in which Mr. Stokes had employed his own method.—DR. E. STOKER suggested, as an explanation of the fact that the patella remained healthy, that the large blood-supply to that bone was not materially interfered with by the operation. The os calcis in Pirogoff's operation lost a large portion of its blood-supply, and so was apt to become necrosed.

MR. WHARTON made a communication on the subject of the Modification of Teale's Amputation, proposed by him in 1868, in a letter to the *Dublin Quarterly Journal of Medical Science*. The point of difference in the modified operation from Mr. Teale's were: (1) the absence of a posterior flap; (2) the shortening of the anterior flap by one-fourth; and (3) a consequent considerable saving of bone. Mr. Wharton was now able to speak practically in answer to the objections brought against his suggestions by Mr. Pridgin Teale and Mr. Jessop. He noticed two amputations of the thigh performed according to his method: one by Mr. William Stokes; the second by Dr. Mapother. He also brought under consideration a case of amputation of the leg by Dr. Mapother, and four cases of amputation of the forearm, by the same plan—the operators being Messrs. Porter, Macnamara, Kelly, and Mayne. He referred to an amputation of the thigh performed by Dr. Illingsworth, of the Royal Artillery; but in that gentleman's absence, and as Mr. Wharton did not witness the operation, he was not in a position to state positively whether the removal of the limb had been effected in strict accordance with the modification suggested. For instance, he was not sure whether the single flap, of which the operation consisted, was rectangular or not.—A discussion ensued, in which Dr. Porter, Mr. Stokes, Mr. O'Leary, and Dr. Darby took part.—MR. O'LEARY stated that, in his experience, the pressure of an arti-

ficial limb was always exerted, not on the tuber ischii, but on the stump. He believed that the saving of bone became a matter of but little importance in cases where the medullary canal was opened. He regarded Mr. Wharton's method as one possessing great advantages in amputations of the leg. In such, the delay necessary in dissecting up the posterior flap was obviated by the procedure in question.—Dr. DARBY dwelt on the necessity of suiting any amputation to an individual case. He always formed his flaps of the skin and subcutaneous areolar tissue exclusively.

## CORRESPONDENCE.

### PATHOLOGY AND TREATMENT OF CHOLERA.

SIR,—I believe that a large majority of the profession—certainly a majority of those who have had practical experience of Asiatic cholera—will now endorse the views of Dr. G. Johnson as to the pathology and treatment of that fell scourge, now unhappily looming in the distance and threatening our shores.

Dr. Johnson has very explicitly described the treatment which he recommends to be adopted in a given case of true Asiatic cholera; but I do not myself apprehend that he has distinctly laid down the treatment of those cases of choleraic diarrhoea which so frequently, though not constantly, precede the advent of the real disease, as the shadow occasionally precedes the substance: yet if these cases partake, even in a minor degree, of the nature of cholera, the more important becomes their successful treatment as tending to prevention.

Permit me through your columns to ask Dr. Johnson whether he would advise to treat such cases on the same principle as that recommended by him in cases of pronounced Asiatic cholera—that is, on the principle of elimination—or whether he would advise that these cases should be treated by means calculated to check the intestinal flux.

I feel assured that many like myself will gladly learn Dr. Johnson's opinion on this very important, and as yet apparently undetermined, point of practice; and I trust that he will kindly answer my query through the medium of your columns, that all readers may have the benefit of his opinion.

I am, etc.,

A. B. BRABAZON, M.D.

12, Darlington Street, Bath, August 30th, 1871.

### CHLOROFORM ACCIDENTS.

SIR,—Allow me to make a few remarks on the criticism of my paper on this subject by Professor Lister in your last number. A considerable portion of his interesting paper is taken up in urging the practice of drawing forward the tongue in cases where, although the movements of respiration continue, no air passes through the larynx; and he thinks that I "practically counsel medical men in general to disregard the drawing forward of the tongue". Now I have never written anything to discourage the practice under the circumstances, but only urged the greater safety of a plan by which such obstruction is prevented from occurring, or from occurring to a degree greater than can be overcome by raising the chin.

The object of my paper was not to discourage the use of the forceps, which may be needed, perhaps, when chloroform is given too freely, but to oppose the statement that giving chloroform upon a towel "without stint" was the safest means of doing it.

Professor Lister says "it is not true that chloroform excites swallowing"; but he admits that it excites the flow of saliva, and that this excites swallowing. Whether the chloroform excites swallowing directly, or by first causing saliva to flow, is not material to the question. I am sure that the stronger the chloroform-vapour, the more frequent the swallowing becomes. I am aware that patients ordinarily swallow very well when under chloroform; but when continued, as it often is, to the point of abolishing reflex movements, it is not so. And, as a matter of fact, blood does occasionally get into the air-passages in operations which cause bleeding inside the mouth.

Professor Lister begs "to refresh my memory with respect to the fact that Dr. Snow ascertained that, when less than about 5 per cent. of vapour existed in the air, the respiration failed before the circulation." He need not do this, for it is the very ground upon which I recommend an apparatus to secure a uniform percentage of chloroform. Dr. Snow tried to invent such an apparatus, but failed to do so. The instrument he used gives off a varying amount of vapour, according to the temperature of the room and of the "water-jacket", and to the atmospheric pressure; and it varies also with the amount of chloroform which has evaporated. The fatal cases which occurred in his practice may be evidence against his apparatus, but not against one which

really does insure accurately the maximum amount of vapour in the air to be breathed.

Professor Lister makes the extraordinary statement that "it is manifest that the average quantity taken into the lungs when this (the towel) method is employed is very greatly below that supplied by Mr. Clover's apparatus." In making this statement, he must have forgotten that the degree of anaesthesia depends upon the amount of chloroform absorbed into the blood; and, to get the same proportion into the blood, it must require the same average percentage of chloroform, whether given uniformly or in varying doses. The experiment of pouring chloroform on a towel, and noting how much evaporates in a given time, gives a very incorrect idea of what occurs in practice, when it is not possible to keep the towel always at the same distance from the face, or make the patient breathe uniformly. The comparison of what happens at the junction of the Arve and the Rhone at Geneva is a bad illustration of what occurs when chloroform is given on a towel. The diffusion of the vapour of chloroform with air in the mouth occurs so rapidly, that they are well intermixed when they arrive at the throat; but, if diffusion did not occur, the vapour should be less pungent, because the pure air coming under the towel should keep on the outside of the current.

Professor Lister says that in Edinburgh, when anything indicated an overdose, it was not failure of the heart, but an obstructed state of the respiration. How, then, does he explain the deaths which have occurred there and elsewhere, where the forceps have been used to draw out the tongue, and artificial respiration set up? These cases ought to have recovered if the circulation was effective at the time the treatment was commenced. Unfortunately, the pulse is so frequently left unwatched, that it is most probable in these cases that the introduction of fresh air into the lungs did not take place until the circulation had ceased. It is obviously impossible to say that the circulation did not fail before the respiration, if it was not watched.

I am, etc.,

JOSEPH T. CLOVER.

3, Cavendish Place, August 2nd, 1871.

## OBITUARY.

### HYDE SALTER, M.D., F.R.S.

WE deeply regret to announce the premature death of this accomplished physician at the age of forty-seven, after a painful illness lasting four months. Always of delicate health, and especially a great sufferer from asthma in early life, he had devoted a large part of his time, patience, and ability to the elucidation of the pathology and treatment of this and other diseases of the chest. His work on *Asthma* has been pronounced to be the best ever published in any language. His amiable character, and deeply religious and kindly mind, endeared him to all with whom he came into contact. In the course of a long career as a hospital physician, he has conferred benefits on many thousands of humble friends, who will hear with deep pain of this loss. His death is pronounced by Dr. G. Johnson, who has recently been in attendance upon him, to have been due to abscess of the lung arising probably from debility, due in no small measure to the enforced abstinence from food necessitated by his asthmatic tendency. He has worked bravely and well for years under great physical difficulties, and has left a name which will long be cherished and honoured, and an example of modest worth and unobtrusive merit which deserves to be commemorated.

### ARTHUR MARTIN A'BECKETT, F.R.C.S.

MR. A'BECKETT, who recently died in Sydney, was born in London in 1812, and after serving the usual term of apprenticeship, became a student in medicine of the London University in 1834, where he obtained several prizes. He became a Licentiate of the Apothecaries' Company in 1835, and passed his examination as a Member of the Royal College of Surgeons in March 1838, and became a Fellow of the same College in December 1855. He served in the British Legion in Spain, from 1835 to 1837, on the staff of Sir De Lacy Evans, and received the order of a Knight of San Fernando, also an order for distinguished conduct on the field of battle, and another cross and gold medal for the battles of San Sebastian and Irun. How much his conduct was appreciated during his service in Spain, is shown from the following extracts from letters by Sir De Lacy Evans and Mr. Rutherford Alcock (now Sir R. Alcock, K.C.B., Her Majesty's Envoy Extraordinary and Minister Plenipotentiary at Peking). Sir De Lacy Evans says, in a letter dated June 19th, 1838—"It is with the greatest pleasure that I offer you the expression of my entire and very high satisfaction with your conduct during the two years of our service in Spain, both as a gentleman and member of our society, and as a medical officer. My own knowledge of your con-

duct, acting, as you were, immediately under my observation, together with the uniformly strong and gratifying reports to me by your superiors of the useful and skilful assistance they derived from you, have, I assure you, impressed me with a sincere interest in your future happiness, prosperity, and professional advancement. Your exertions in our large hospitals in Spain, as staff-surgeon, have given advantages, in point of experience, of a various description, which few, I believe, at your age have possessed." In the letter from Mr. Rutherford Alcock, late Deputy Inspector-General of Hospitals, British Legion, Spain, dated June 18th, 1838, he says:—"I must not allow you to embark for another land without conveying to you not only my best wishes for your prosperity, but my conviction that you cannot fail to attain success in the practice of your profession. In the service of Spain, where, for two years, you were constantly under my observation in the field, and in the hospitals, your gallantry and intelligence in the first, and uniform zeal and ability in the last, were too obvious to be either overlooked or forgotten. When the Royal Military Order of San Fernando was conferred upon you, I considered it due to you, not less for your exertions and services under fire, than for the more painful, trying, and important duties which you so conscientiously discharged in the wards of our hospitals in Vittoria and San Sebastian. I have shared the same quarters with you, slept in the same bivouac, and watched you and worked with you among sick and wounded. In all these various situations your conduct as a gentleman, your skill and humanity as a surgeon, and your ready compliance as a soldier with all instructions however hazardous or trying the execution, makes me regret that a land so distant should render our meeting again for many years improbable."

He embarked from England for Sydney, New South Wales, in June 1838; and by his indefatigable exertions, zeal, and high professional knowledge, he succeeded in obtaining, and steadfastly maintaining, a high position, and an extensive practice in the colony. During a residence of upwards of thirty years in Sydney, he twice visited Europe. He was one of the first members of the Legislative Council of New South Wales, for several years one of the surgeons of the Benevolent Asylum, and, previously to his last visit to Europe, an examiner of the Medical Faculty of the University of Sydney, and a trustee of the Australian Museum. He was a trustee of the Sydney Grammar School, and a Fellow of the Royal Geographical Society of London. He was brother to the late Gilbert A'Beckett; to the late Sir William A'Beckett, Chief Justice of Victoria; and the Hon. Thomas A'Beckett, of Melbourne.

In noticing his death, a Sydney paper thus speaks of him:—"The death of the late Arthur Martin A'Beckett is a great loss to the medical profession, as well as to the community at large. As a medical practitioner he has long been favourably known in Sydney, and his skill and ability in the treatment of disease have always been held in the very highest estimation by his brother practitioners as well as by the public. But skill and ability were not the only qualifications of our departed friend. The best qualities of head and heart were his. Sterling honesty and outspoken truthfulness were his great characteristics. Honest and honourable himself, he was the fearless and unflinching opponent of every form of dishonest and dishonourable practice in others. To every species of imposture he was a sworn foe. His aim ever was to render the profession which he practised worthy of the respect and esteem of the world, and no line of conduct met with his approval which was not in accordance with this end. Such men as Mr. A'Beckett we can badly afford to lose."

#### JOHN WHITE, M.R.C.S.

WE regret to have to announce the death, on the 28th July, after a short illness, of Mr. John White, at his residence, Storey's Gate, Westminster, at the age of 73. Mr. White became a Licentiate of the Society of Apothecaries in 1819, and a member of the Royal College of Surgeons (England) in 1821. His practice in Westminster extended over a period of more than forty years. Added to considerable professional knowledge and skill, he had also acquired for himself a name for kindly sympathy and courteous urbanity amongst all classes of his patients, by many of whom he was warmly esteemed and respected as a sincere friend, and by whom he will long be held in grateful memory.

#### ROBERT SHIPMAN, F.R.C.S., GRANTHAM.

WE regret to announce the death of Mr. Robert Shipman, on July 25th last, from renal dropsy, at the early age of fifty-four years. Mr. Shipman was a pupil of the late Mr. Keal, of Oakham; and after prosecuting his studies at St. Thomas's and Guy's Hospitals, he became a Licentiate of the Society of Apothecaries, and a Member of the Royal College of Surgeons in 1839, and obtained the Fellowship of the Col-

lege in 1854. Besides a large and high-class private practice, he held the appointments of Surgeon to the Grantham district of the Great Northern Railway, and Surgeon of the second battalion of Lincolnshire Volunteer Rifles. He was formerly Surgeon to the Royal South Lincoln Militia. He was also a member of the Borough Corporation, an Alderman, and Justice of the Peace. Although his remains were buried at a distance of some miles from his residence, they were followed to the grave by about forty gentlemen unconnected with his family, including the Mayor and most of the Corporation of Grantham. His kind disposition, urbane manners, and freedom from professional jealousy, had won him the respect and esteem of not merely his professional brethren, but of all who knew him.

#### WILLIAM FAVELL, F.R.C.S., SHEFFIELD.

AMID the universal regret of the medical profession of Sheffield, one of its oldest members, Mr. William Favell, has passed away, beloved and respected by all his brethren and mourned by a large number of his patients. Mr. Favell was admitted a member of the Royal College of Surgeons in 1821, and became one of the most successful practitioners in Sheffield. His father, the late Mr. John Favell, was one of the surgeons to the Infirmary; his brother, Dr. Charles Favell, who died many years ago, was one of the physicians to that institution; and his son, Mr. W. F. Favell, is now one of the surgeons connected with it. Mr. Favell has almost, it may be said, died in harness, for it was only on entering upon his seventy-fifth year that he, nominally at any rate, retired from the more active duties of his trying and laborious profession, although up to a few weeks of his death old patients gladly sought the advice of one in whose skill and large experience they had justly every confidence. Full of years Mr. Favell has passed away, and few men among the many of Sheffield's most worthy sons will be more regretted. An intimate friend of the deceased gentleman writes to a local paper:—"Although the duties appertaining to a large family and a very extensive practice, prevented Mr. Favell from taking an active part in any of our public institutions or societies, few men were so universally esteemed in the sphere in which he moved, or won so entirely the confidence and admiration of a numerous circle of friends and patients. Careful and cautious in his treatment, clear in judgment, and kindly in manner, with always a genial turn of humour and sparkle of wit that made even his most melancholy visit to the sick-bed bring a ray of sunshine with it; his memory will long be cherished by those who knew him and reaped the benefit of his long experience and wise counsels. Although arrived at the advanced age of seventy-four, in appearance he was scarcely sixty, and his manners and conversation had all the freshness and vivacity of youth; while his erect figure, and handsome countenance will long dwell on the memory as a pleasant reminiscence, and a type of nature's true nobility." Mr. Favell was for many years a member of the British Medical Association, and some years ago filled the office of President of the Yorkshire Branch. He died on August 25th, in the seventy-fifth year of his age.

#### CHARLES ASPRAY, L.S.A.

CHARLES ASPRAY was born on November 22nd, 1804, at Olney, Bucks, where his family had followed the practice of medicine from father to son for six generations. When quite young, his father sent him to London to study at Guy's Hospital. In 1826, he became a Licentiate of the Apothecaries' Company. For twenty-six years he laboured in his profession, holding many union and club appointments. To the great regret of his numerous friends, he left Olney in 1852, wishing to give his children the advantage of a London education. For the last three years he had suffered considerably from mental depression, occasioned by hepatic derangements; his weakness was very much increased by a chronic bronchitis; he gradually sank and died on August 2nd, aged 66, the immediate cause of his death being a disease of the liver.

#### ROBERT MANN, M.R.C.S., LATE OF MANCHESTER.

MR. ROBERT MANN, late of Manchester, who died at his residence, Plas Elwy, St. Asaph, on the 14th instant, was born August 25th, 1790, near the Tower of London; his father, a Captain in the Grenadier Guards, being then quartered there. He served his time as a pupil of Dr. Anderson, of Newcastle-on-Tyne. Whilst with him, he was entrusted almost wholly with a large colliery practice; and the writer of this notice has often heard him say that he had so much hard work night and day, that he frequently went to sleep whilst travelling on horseback. After taking his diploma in 1812, he entered the 2nd battalion of Grenadier Guards as assistant-surgeon, and shortly afterwards was transferred to the 3rd West York Militia, in which regiment he was also ensign,

and saw some active service in Ireland. After the disembodiment of this regiment, he commenced his career of civil practice at North Shields, and there married Eliza, third daughter of the Rev. Moses Manners, Rector of All Saints, Newcastle-on-Tyne. His father, Captain Mann, being shortly afterwards appointed barrack-master in Manchester, he was induced to commence practice there, at the same time assisting his father in his duties. In a very short time after this he became actively engaged in a large general practice. Last year he retired finally to his country residence at St. Asaph, apparently in good health both of body and mind. The severe winter, however, kept him in close confinement to his house, and caused his health to fail. In May last he had a slight attack of paralysis, after which he gradually became weaker, and died on August 14th. He was interred at St. Asaph. The great respect in which he was held by the whole neighbourhood was evident in the shops being shut and the blinds drawn while the funeral cortege passed by. His old friend and pastor, the Rev. Canon Bently, officiated at the funeral.

The late Mr. Mann was for many years a member of the British Medical Association, and of the Literary and Philosophical Society of Manchester.

## MEDICAL NEWS.

### THE GENEVA CONFERENCE.

It is announced that the Conference prior to the Vienna Congress, which we recently mentioned as being under arrangement, will not take place. Both Germany and France have declined to send representatives, on the alleged ground that it is "unpractical and useless". It is further stated that a new organisation is already being formed in Germany—notably in Berlin—the task of which it shall be to replace the Geneva Convention by an institution based on strictly military principles.

**UNIVERSITY OF LONDON.**—The following is a list of the candidates who have passed the recent First M.B. Examination.

#### First Division.

Branfoot, Henry Seymour, Guy's Hospital  
Buchanan, Arthur, Guy's Hospital  
Colgate, Henry, University College  
Dobson, Andrew, Queen's College, Birmingham  
Firth, Charles, St. Bartholomew's Hospital  
Rayne, Charles Alfred, University College  
Schäfer, Edward Albert, University College  
Skerritt, Edward Markham, B.A., University College  
Smith, George Francis Kirby, Guy's Hospital

#### Second Division.

Addy, Boughton, St. Thomas's Hospital  
Appleyard, John, University College  
Avery, Henry, Guy's Hospital  
Baker, Edward Cresswell, St. George's Hospital  
Blake, Samuel H., University College  
Boddy, Hugh Walter, Manchester Royal School of Medicine  
Burn, G. W., St. Bartholomew's Hospital  
Crespin, E. R. B., Guy's Hospital  
Dyson, W. R. A., University College  
Harvey, Charles William, University College  
Kennedy, Edward, B.A., Manchester Royal School of Medicine  
Kerr, David Neilson, M.A., University of Glasgow  
Lees, David Bridge, University of Cambridge  
Lindsay, John, Liverpool School of Medicine  
Parry, Thomas Sharpe, University College  
Sturge, William Allen, Bristol Medical School and University College

Excluding Physiology.

#### Second Division.

Dundas, George Albert, Guy's Hospital  
Holmes, Richard, St. Mary's Hospital  
Nicolson, Arthur, King's College

Physiology only

#### First Division.

Bradford, Arthur Mudge, Guy's Hospital

#### Second Division.

Davies, Daniel Arthur, University College  
Mann, Herbert Campbell, King's College  
Gore, Edmund Henry, St. Mary's Hospital  
Sommerhayes, William, St. Thomas's Hospital  
Taylor, John (B.), Guy's Hospital  
Williams, William, Guy's Hospital

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, August 17th, 1871.

Allen, Marion Henry, Regency Square, Brighton  
Birk, Robert, Letchfield  
Bosser, John Henry, Barton in Ashfield  
Butler, Francis William, Spring Grove House, Beckham

Hosford, Joseph Alexander, Cumberland Street, Barnsbury  
Sarjant, Josiah John, Millwall, Poplar  
Steele, Edward Henry, Dorchester

The following gentlemen also on the same day passed their first professional examination.

Dixon, Thomas James, Guy's Hospital  
Pitts, Robert Zaccheus, Middlesex Hospital  
Murphy, Robert William, Guy's Hospital  
Stoney, Percy Butler, St. Bartholomew's Hospital

The following gentleman passed his examination in the science and practice of medicine, and received a certificate to practise, on Thursday, August 24th, 1871.

Newberry, William John, Liverpool Road, Holloway

The following gentlemen also on the same day passed their first professional examination.

Dickinson, William Wood, Guy's Hospital  
Hamlin, William Thorne, St. Mary's Hospital  
Maybury, Aurelius Victor, St. Thomas's Hospital

### MEDICAL VACANCIES.

The following vacancies are announced:—

ATCHAM UNION, Salop—Medical Officers for the St. Chad's and St. Mary's Districts.  
BATTLE UNION, Sussex—Medical Officers for the Mountfield and Brightling Districts.  
BRISTOL LUNATIC ASYLUM, Stapleton—Assistant Resident Medical Superintendent.  
BRISTOL POLICE—Surgeon.  
BRISTOL ROYAL INFIRMARY—Dispenser.  
CHRISTCHURCH UNION—Medical Officer for the Eastern District.  
EXETER DISPENSARY—Surgeon.  
GOVAN COLLIERY, Rutherglen—Surgeon.  
GOWER UNION—Medical Officer and Public Vaccinator for the Western District.  
ISLINGTON—Medical Officer of Health and Analyst.  
KING'S LYNN UNION, Norfolk—Medical Officer to the Workhouse and Infirmary.  
LEXDEN and WINSTREE UNION, Essex—Medical Officer for District No. 8.  
MONMOUTH HOSPITAL and DISPENSARY—Dispenser.  
NORFOLK and NORWICH HOSPITAL—House-Surgeon.  
NORTHERN HOSPITAL, Liverpool—Physician.  
ST. SAVIOUR'S UNION, Surrey—Medical Officer for District No. 3.  
SOUTHAMPTON UNION—Medical Officer for District No. 2.  
TOWCESTER UNION, Northamptonshire—Medical Officer and Public Vaccinator for the Towcester District and the Workhouse.  
UNST, Shetland—Parochial Medical Officer and Public Vaccinator.  
WEST RIDING OF YORKSHIRE CONSTABULARY—Surgeon for the Mirfield District.  
YORK UNION—Medical Officer and Public Vaccinator for District No. 4.

### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

MULHOLLAND, Owen, L.R.C.P. Edin., appointed Medical Officer, etc., for the Tullyvin Dispensary District of the Cotehill Union, co. Cavan.  
SHIPMAN, George W., Esq., appointed Surgeon to the Grantham District of the Great Northern Railway.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

#### DEATHS.

ANDERTON, Henry, L.R.C.P. Ed., at Newbury Park, near Birkenhead, aged 87, on August 1st.  
DAY, William M. H., Esq., Assistant House-Surgeon of the Bristol Lunatic Asylum, at Bath, suddenly, aged 53, on August 29th.  
HALL—On August 29th, at Sneinton, near Nottingham, aged 83, Sarah, sister of the late Marshall Hall, M.D.  
MANN, Robert, Esq., Surgeon, late of Manchester, at Plas Elwy, St. Asaph, aged 80, on August 14th.  
NEWBOLD, Ambrose, M.K.Q.C.P., at Carnew, co. Wicklow, aged 44, on Aug. 7th.  
PEEKINS, John S. S., Esq., Surgeon, at Exeter, from the bursting of an abdominal aneurism, aged 26, on August 17th.

**ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.**—The following scholarships and prizes have been awarded for the winter and summer sessions 1870-71:—Jeafreson Exhibition—E. Crétin. Senior Scholarship in Medicine, Surgery, Materia Medica, and Therapeutics—H. E. Bridgeman, W. Farmer, and T. Stafford (equal). Senior Scholarship in Anatomy, Physiology, and Botany—1, C. Firth; 2, R. W. Leftwich. Junior Scholarships—1, E. Crétin; 2, P. H. Dicken; 3, A. F. Stevens. Kirkes Medal—D. P. James. Bentley Prize—H. Taylor. Practical Anatomy (Senior)—Foster Prize—P. Benson; 2, H. J. Hott; 3, H. A. Nicholls and H. Wilcox; 5, E. Milner, F. W. Strugnell, and J. L. Whitsett; 8, J. F. Dixon; 9, P. Haig; 10, W. L. Webber. Wix Prize—H. E. Bridgeman. Hichens Prize—F. E. Jackson. Practical Anatomy (Junior)—Treasurer's Prize—G. Andrew and S. Verco; 3, J. T. Duncan; 4, A. F. Stevens; 5, J. Mills; 6, H. Boulter and P. H. Dicken; 8, J. J. Weakley; 9, J. W. Groves; 10, E. J. Burgess.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAY ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.

WEDNESDAY .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY ... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.

FRIDAY ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

SATURDAY ... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with *halfpenny* stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

NOTICE TO ADVERTISERS.—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

## PORTABLE GALVANIC BATTERY.

SIR,—In answer to the inquiries of "An Associate," I beg to state that Gaiffe's pocket batteries are surpassed, in my opinion, by Duchenne's portable battery, which, although somewhat larger (seven and a half by four and a half by two and a half inches), is a far more perfect instrument. It is made by Charière, and answers every purpose. One of the great objections to Gaiffe's pocket-battery is, that the electric current becomes after a few minutes very feeble, whereas no diminution in the strength of the current is noticeable in Duchenne's instrument for a long time. The current in this latter battery is sufficiently powerful to kill a small animal, and can be regulated, so that, on the other hand, it may be employed to galvanise the testicles. A full description of it is contained in Dr. Duchenne's (*de Boulogne*) "De l'Electrisation Localisée."

I am, etc., CORNELIUS B. FOX, M.D., M.R.C.P., Lond.

AN "ASSOCIATE" asks what is a Störhr battery? There are, I think, two: one a zinc-carbon combination, and another where Störhr has arranged six pairs of Bunsen cells, so that the metals can be lifted out when not in use. The latter is very powerful. Then, as to an apparatus at once small, strong, portable, for resuscitation of drowning cases, still-born infants, apnoea under chloroform, etc., it is well to graduate the current, to have large moist sponge electrodes pressed firmly over the phrenics at the outer borders of the sterno-cleido-mastoid and lower end of the scapuli, to interrupt the current three times a minute, and avoid shock of sudden closure of a severe current. The Gaiffe battery, with elements acted on by bisulphate of mercury, is weak. Better is Remak's; better still, perhaps, the small electromagnet turning with a handle. I have used such an one: it is easily carried in an ordinary bag.

I am, etc., CHARLES KIDD, M.D.

Sackville Street, August 14th, 1871.

P.S.—It is satisfactory to find that the points so long urged in the JOURNAL as to this remarkable means of saving life, are now so widely recognised by Beard and Rockwell in America, Ziemssen, Remak, and others at this side of the Atlantic. Great care is required as to sudden shock in chloroform accidents, or applying the force to the heart direct, or pneumogastric; it is scarcely exact, however, to doubt that the right side of the heart is obstructed. Lallein, and Perin, and Duroy set that point at rest long ago. And the use of the battery is obviously to relieve the right heart through a newly set-up artificial respiration.

SIR,—An "Associate" can obtain Gaiffe's apparatus from Mr. F. MacElroy, Electrician, 5, Caermarvon Street, Cheetham Hill, Manchester. Let him ask for "Appareil d'Induction Volta-Faradique, Breveté S. G. D. G., A. Gaiffe, à Paris." There is only one thing needed to make it perfection, and that is, that the batteries shall not leak. Believing, as stated, that they would not leak, I invested in one (£3 3s. the price, I think); but in a very short time I found that it was a case of misplaced confidence; a leak did occur, and the metallic connections being dissolved, it is not difficult to imagine the effect or result on the working of the coil. The instrument is powerful enough for all medical purposes where an interrupted current is advisable; and whenever the makers can warrant that leakage is impossible, there will then be no instrument, in my opinion, which is its superior.

I am, etc., THOMAS SKINNER, M.D.

Dunedin House, Liverpool, August 12th, 1871.

SIR,—In answer to the inquiries of "An Associate" in last week's JOURNAL, about Gaiffe's battery, I beg to inform him that Ernst, of Charlotte Street, Fitzroy Square, has one.

I am, etc., GEORGE CHARLES COLES.

20, Great Coram Street, Russell Square, W.C., August 22nd, 1871.

## MEDICAL WITNESSES' FEES.

SIR,—I should feel much obliged by your opinion of the following case. On Friday, August 11th, I was summoned (not in pen and ink, but by a policeman) to appear and give evidence before a magistrate in a case of assault. The prisoner was remanded till the following Monday, when I had again to appear. He was further remanded till Thursday, the 17th, when I was obliged to attend for the third time. The Clerk to the Magistrates asked me if I expected a fee for my attendance; and when I said yes, he informed me that I must sue the defendant for it, who, I may say, is only in the receipt of one and three-pence a day, as a pension. I did not, under the circumstances, claim it. Could you tell me whether I have a right to demand the same from the clerk? If you think this is worthy of insertion in your JOURNAL, I should be glad to see it published.

I am, etc., W. D. HYDE, M.R.C.S.E., L.A.C.

Hemel Hempstead, Herts, August 17th, 1871.

## THE COMMITTEE ON "CHOLAGOGUES."

SIR,—May I without impertinence ask, through your columns, how it is that the report of what I understood to be a Committee of the British Medical Association on the action of mercury, etc., is constantly announced in the advertising columns of the JOURNAL as the report of the British Association? I believe Dr. Hughes Bennett obtained, also, a grant from the British Association for the expenses of his Committee. But as I believe something like £150 or £200 has been granted him from the British Medical Association—a by far less wealthy and unsubsidised body—it seems to me a little hard that our Association should be altogether ignored. If this Committee be a Joint Committee of the British Medical Association and the British Association, that should appear on the face of it, as in the case of the State Medicine Committee; as it is, I am not altogether satisfied with the treatment which our Association receives in return for this, its most extensive and liberal grant.

I am, etc., MERCURY.

## "DYKE V. THE ST. PANCRAS GUARDIANS" APPEAL FUND.

DR. BATHURST WOODMAN begs thankfully to acknowledge the receipt of the following subscriptions to the Fund now being raised for the purpose of carrying on the appeal in the above suit: the history and particulars of which, together with a report of the trial, he will be happy to forward on application.

Mr. Morrant Baker, F.R.C.S., St. Bartholomew's Hospital -	£1 1 0
Dr. Barnes, Grosvenor Street -	1 1 0
Dr. Billing, Grosvenor Gate -	1 1 0
F. Gordon Brown, Esq., M.R.C.S., Finsbury Circus -	0 10 6
Dr. Andrew Clark, Cavendish Square -	2 2 0
George Critchett, Esq., F.R.C.S., Harley Street -	2 2 0
T. B. Curling, Esq., F.R.S., Grosvenor Street -	2 2 0
Dr. Herbert Davies, Finsbury Square -	2 2 0
Dr. Langdon Down, Welbeck Street -	2 2 0
Dr. C. R. Drysdale, Southampton Row -	1 1 0
Dr. Edmunds, Fitzroy Square -	2 2 0
Peter Gowlland, Esq., F.R.C.S., Finsbury Square -	1 1 0
Dr. Hardwicke, Maida Hill -	1 1 0
Jonathan Hutchinson, Esq., F.R.C.S., Finsbury Circus -	1 1 0
Dr. Hughlings Jackson, Bedford Place -	1 1 0
Dr. Little, Brook Street -	2 2 0
James Luke, Esq., F.R.S., Maidenhead -	1 1 0
Dr. Morell Mackenzie, Weymouth Street -	2 2 0
C. F. Maunders, Esq., F.R.C.S., New Broad Street -	2 2 0
F. B. Pearce, Esq., F.R.C.S., Haverstock Hill -	2 2 0
Walter Rivington, Esq., F.R.C.S., Finsbury Square -	1 1 0
Edward Symonds, Esq., Camden Town -	2 2 0
James Teevan, Esq., F.R.C.S., Chesham Street -	2 2 0
James Watkins, Esq., Gloucester Road -	1 1 0
Dr. W. Bathurst Woodman, Christopher Street -	1 1 0
A. K. -	1 1 0
One Behind the Scenes -	1 1 0
A Hater of Injustice -	1 1 0
F.R.C.P. -	0 10 6

Further subscriptions are earnestly and respectfully requested, and may be forwarded to Dr. Bathurst Woodman, Honorary Secretary, 6, Christopher Street, Finsbury Square, E.C., or paid in to the account of the Fund at the London and Westminster Bank, Lothbury.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, August 26th; The New York Medical Record, August 18th; The Boston Medical and Surgical Journal, August 18th; The Madras Mail, June 17th; The Shield, August 26th; The Philadelphia Medical Times, July 10th; The Philadelphia Medical Independent, August 12th; The Birmingham Morning News, August 25th; The Sheffield and Rotherham Independent, August 29th; The Norwich Argus, August 26th; etc.

## COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. Barham, Truro; Mr. Joseph Lister, Edinburgh; Dr. A. P. Stewart, London; Mr. W. D. Husband, York; Mr. Dyke, Merthyr Tydfil; Dr. Ferrier, Aberdeen; A. F.; Mr. W. P. Swain, Devonport; Dr. Spender, Bath; Mr. Symptom, Lincoln; Dr. Brumwell, Mossley; Mr. R. W. Egan, Dublin; Dr. J. I. Mackenzie, Sidmouth; Dr. Henry Bennet, London; Dr. Charlton, Newcastle-upon-Tyne; Dr. W. B. Woodman, London; Dr. Littleton, Plymouth; Mr. Wm. Eddowes, Pontesbury; Dr. Griffiths, Oldcastle, co. Meath; Dr. Wiltshire, London; The Rev. Dr. Haughton, Dublin; Dr. Rushton Parker, Liverpool; M.R.C.S. Eng.; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Dr. Nankivell, Torquay; Mr. Ashton, Walton-le-Dale; Dr. Marshall, Preston; Dr. Gilbertson, Preston; Dr. Brabazon, Bath; Mr. Newbold, Wexford; Mr. Higginbottom, Nottingham; Our Manchester Correspondent; Mr. Nash, Hatch Beauchamp; Dr. C. B. Fox, Scarborough; Dr. Kidd, London; Dr. George Johnson, London; Mr. Benson Baker, London; Mr. Scattergood, Leeds; Dr. Skinner, Liverpool; Mr. Hemingway; Dr. Nicol, Bradford; Dr. Collyer, London; Dr. Aitken, Edinburgh; Dr. Meadows, London; etc.

# EDUCATIONAL NUMBER.

## PLAIN TRUTHS TO MEDICAL STUDENTS.

THE few words which we shall offer to students this year will be, in the main, a repetition of what we said last year. We stepped aside then from the beaten track, and, in lieu of the traditional exhortations and glorifications, we told them plainly of shortcomings which mar their usefulness and success in after-life, and disfigure their course of education. The past year has singularly proved the usefulness and attested the fruitfulness of the advice which we offered. We repeat it. The students who come to our medical schools are in a large proportion deficient in preliminary education, and wholly untrained in any kind of scientific knowledge or method. They come too young, and too little instructed. They come often under the influence of effete traditions, and looking for success under conditions which can and ought only to bring failure. No student should enter a medical school till he is seventeen years of age: he should look upon the prescribed four years not as the *maximum*, but as the *minimum*, period of study. He should bring to his medical school not only the ordinary humanities of a little Latin and Greek, but a well grounded preliminary acquaintance with the facts of natural science.

We see with great satisfaction that there is a growing tendency to demand of students at their stages of subsequent candidature for diplomas a knowledge of the things themselves which constitute the art and science of medicine, and not merely of that which may be said or written about them. The student will remember that he will henceforth be asked at the day of trial to put up a fracture, instead of repeating a lesson how it ought to be put up; to discriminate and describe specimens under the microscope, instead of writing out descriptions which he has committed to memory; and to produce and reason upon chemical reactions instead of merely enumerating them. It is a painful but not unnatural consequence of the introduction of these practical tests that students coming, as we have said, half-educated and ill-trained to our medical schools, and still under the influence of the old traditions of cramming and book-work, have failed in very large proportions to satisfy the actual demands of their examiners, and still more so their consciousness of that standard which ought to be reached. We have warned students of the folly of neglecting the "refinements" of microscopy, of chemistry, and of physics, as not belonging to every-day practice and medical use. These are, on the contrary, now the daily and necessary implements of medical science. They lie at the foundation of the simplest manipulations; of successful pill-making; of rational prescribing; of the moral right to order a black draught or to prescribe a shower-bath.

There are still floating about in surgeries and wards, and in the back places of medical talk, sneers at scientific medicine, laudations of the rule of thumb, and much vapouring about experience. Let our student beware of such snares, and keep his head out of this mist. Every dose of medicine which he gives is a scientific experiment, performed under peculiarly difficult and complex circumstances. To be capable of observing or recording its effects in a manner worthy of any attention, or other than delusive, and more mischievous than useful, requires a very thorough physical, chemical, and logical training, such as the student will only succeed in obtaining by the utmost labour that he can devote to his work throughout his four years of studentship. A word of caution against the contempt sometimes expressed for prizes and rewards. There are exceptions to every rule; but, almost without exception, those who have taken the highest and most numerous school-prizes have been rewarded by the highest and most noble achievements in science in after-life. For what is called success in practice, other qualities also are needed. Balance of character, steadiness of purpose, rectitude and self-denial, sagacity, and kindness of manner and of purpose, are characteristics which do not necessarily accompany intellectual activity and strenuousness: they have the highest value in life, and, both in school and out of it, will help to make or mar a man's career. But those idle

persons who sneer at school distinctions are no friends to the student or to science. In any case, however, the distinction is only the badge; it pretends to imply knowledge. If the badge be won by any dodge, and in the absence of that which it typifies, it is as worthless as are all other shams. It must be the object of the student to get real knowledge, that he may be able to do his work well, and to respect himself while he is helping others. In proportion to the reality of his knowledge he may account himself successful. In respect, therefore, to all that he learns, he must try to look upon books not as containing the things which he is to learn, but as guiding him to the things which he is himself to inspect in very fact and compare with book-descriptions. He must no more think himself a surgeon from being able to quote by heart pages of a treatise on surgery, than he would think himself an Alpine climber because he could recite pages of Murray's *Handbook to Switzerland*. He should never content himself without handling and seeing and doing all that can be handled, seen, or done. He will find in the laboratory, the dissecting-room, the microscope-room, the ward, the out-patient-room, and the dispensary, his proper fields for work. He will find there the things which belong to his work; and he must think nothing achieved till he has compared facts and accomplished the manipulations of which his books can only tell him. He will find that, for early clinical study and preliminary practical work of all kinds, provincial hospitals afford much readier occasions, and greater wealth of unoccupied space and material, than the often overcrowded wards and pharmacies of London hospitals; and we advise the working student to avail himself of their opportunities—now too little used.\*

## CHANGES IN THE HOSPITALS AND MEDICAL SCHOOLS.

THE following changes in the hospitals and medical schools have taken place since the commencement of the last winter session.

At St. Bartholomew's Hospital, Mr. Luther Holden has retired from the chair of Anatomy, which he has long and honourably filled. Mr. Callender, for some time the colleague of Mr. Holden, retains the lectureship; in which Mr. Thomas Smith is now associated with him. Dr. Russell has succeeded the late Dr. Matthiessen as lecturer on Chemistry and teacher of Practical Chemistry. Mr. Willett succeeds Mr. Langton and Mr. Marsh in teaching Operative Surgery, and Mr. Symons is appointed demonstrator of Practical Physiology. Dr. Claye Shaw has been appointed lecturer on Psychological Medicine in the room of Dr. Thorne Thorne. The resignation by Sir James Paget of his post as surgeon of the hospital has been followed by his appointment as consulting-surgeon, the promotion of Mr. Callender from the office of assistant-surgeon to that of surgeon, and the appointment of Mr. Morratt Baker as assistant-surgeon.

The staff of the Charing Cross Hospital has just sustained a severe loss in the death of Dr. Hyde Salter, the senior physician to the hospital, and lecturer on Medicine. His successor has not yet been appointed. Dr. Pollock has been promoted to a full physicianship; and Dr. Douglas Powell has been appointed assistant-physician. The surgical staff has been increased by the appointment of Mr. Fairlie Clarke as assistant-surgeon.

At St. George's, Mr. Pick is associated with Mr. Holmes as Lecturer on Surgery, and replaces Mr. Rouse as Teacher of Operative Surgery. A special course of lectures by Dr. Lockhart Clarke, on Diseases of the Brain and Spinal Cord, is announced for the winter session. Mr. Dalby has been appointed Lecturer on Aural Surgery.

At Guy's Hospital, Dr. Pavy has been promoted to the rank of physician, and Dr. Pye-Smith has been appointed assistant-physician. Mr. Cock has resigned office as senior-surgeon and has been appointed consulting-surgeon; Mr. Bryant, late senior assistant-surgeon, has consequently become full surgeon; and Mr. Howse and Mr. Davies—

\* See *Preliminary Medical Education at Provincial Hospitals*. By William Paul Swain, F.R.C.S., Devonport. London: Churchill. Price Sixpence.

Colley have been appointed assistant-surgeons. Dr. Hilton Fagge is associated with Dr. Moxon in teaching Pathological Anatomy; and Dr. Thompson Dickson has been appointed Lecturer on Mental Diseases.

In King's College, Mr. Bloxam has succeeded the late Dr. Miller as professor of Chemistry; and Dr. Edgar Sheppard has been appointed professor in the new chair of Psychological Medicine. Mr. Henry Smith has become full surgeon to the hospital; and Mr. Wood replaces Mr. Partridge as one of the lecturers on Clinical Surgery.

At the London Hospital, Dr. Hughlings Jackson has been promoted to the post of physician. Dr. Prosser James has succeeded Dr. Down as lecturer on *Materia Medica*; and Dr. Meymott Tidy has taken Dr. James's place as lecturer on Forensic Medicine in conjunction with Mr. Rodgers.

Numerous changes have occurred at St. Mary's Hospital. Dr. Sibson has retired from the office of physician, Mr. Samuel Lane from that of surgeon, and Dr. Tyler Smith from that of obstetric physician—all in consequence of the expiry of their term of appointment. Dr. Broadbent has been promoted to the post of physician, and Dr. J. A. Nunneley has been appointed assistant-physician. Mr. E. Owen has been appointed assistant-surgeon; and Dr. A. Meadows obstetric physician and lecturer on Midwifery. Mr. Norton is the sole lecturer on Anatomy, Mr. Gascoven having taken the place of Mr. Spencer Smith as Mr. J. R. Lane's colleague in the chair of Surgery. Mr. Wright teaches Chemistry and Practical Chemistry in the room of Dr. W. Russell, appointed to St. Bartholomew's Hospital. Dr. Broadbent has been appointed lecturer on Medicine in conjunction with Dr. T. K. Chambers, *vice* Dr. Handfield Jones. Dr. Nunneley teaches Histology in place of Dr. Lawson; and Dr. Cheadle Pathology in the room of Dr. F. Payne, who has been transferred to St. Thomas's Hospital. Mr. Howard Hayward has succeeded Mr. Sercombe as lecturer on Dental Surgery.

At the Middlesex Hospital, Dr. Murchison, in consequence of his appointment to St. Thomas's Hospital, has resigned the office of physician and lecturer on Medicine, and is succeeded in the last named post by Dr. Greenhow, who consequently retires from the joint-lectureship on Medical Jurisprudence. Dr. Burdon Sanderson has vacated the office of assistant-physician; and Mr. Henry Arnott, having been appointed to St. Thomas's Hospital, has retired from the office of assistant-surgeon. Dr. Cayley and Dr. John Murray have been appointed assistant-physicians; and Mr. Henry Morris assistant-surgeon. Mr. Lowne has become lecturer on Physiology in the room of Dr. Ferrier, and teacher of Histology in place of Dr. Cayley. Dr. Murie lectures on Comparative Anatomy in place of Dr. Spencer Cobbold. Mr. Taylor has retired from the chair of Chemistry, leaving it occupied by Mr. Heisch alone. Operative Surgery is to be taught by Mr. Hulke, Mr. Lawson, and Mr. Morris. Dr. John Murray is announced to give a course of Laryngoscopic Demonstrations.

The transference of St. Thomas's Hospital to the new buildings is attended with an increase of the medical and surgical staff, and some changes in the *personnel* of the school. The appointments in the hospital staff have been those of Dr. Murchison as physician; of Drs. Stone, Ord, John Harley, and Payne, as assistant-physicians; of Mr. Mac Cormac, Mr. F. Mason, and Mr. H. Arnott, as assistant-surgeons; and of Mr. Liebreich as ophthalmic surgeon. In the school, Dr. John Harley succeeds Dr. Bristowe as the colleague of Dr. Ord in the lectureship on Physiology; Mr. F. Mason and Mr. Wagstaffe become lecturers on Anatomy, in place of Mr. Sydney Jones; Dr. Murchison lectures on Medicine in place of Dr. Barker, conjointly with Dr. Peacock; Mr. S. Jones becomes the colleague of Mr. Le Gros Clark in the lectureship on Surgery. Mr. Solly having retired from that chair as well as from the office of surgeon to the Hospital; Mr. Stewart lectures on Comparative Anatomy in place of Dr. Ord; and Mr. Liebreich on Ophthalmic Surgery in the room of Mr. Sydney Jones. Special instruction in Operative Surgery will be given by Mr. Croft and Mr. Mac Cormac.

At University College Hospital, Dr. Charlton Bastian has been

promoted to the post of physician; and Mr. Berkeley Hill and Mr. C. Heath have in like manner become full surgeons. Mr. Marcus Beck has been appointed teacher of Surgical Pathology; and Dr. Roberts assistant-teacher of Clinical Medicine.

At the Westminster Hospital, Mr. Hillman has retired from the office of surgeon; and Mr. Mason, having accepted an appointment in St. Thomas's Hospital, from that of assistant-surgeon. Mr. R. Davy and Mr. Thomas Cooke have been appointed assistant-surgeons. Dr. Basham has retired from the lectureship on Medicine, leaving it occupied by Dr. Anstie alone; who again is succeeded by Dr. Sturges as Lecturer on *Materia Medica*. In consequence of the retirement of Mr. Mason, Mr. Holthouse is the sole occupant of the lectureship on Surgery. Dr. R. J. Lee succeeds Dr. Sturges as the co-lecturer with Dr. Gibb on Medical Jurisprudence. Dr. Maclure, the lecturer on Physiology, will also teach Practical Physiology.

At Queen's College, Birmingham, Mr. J. F. West has retired from the lectureship on Anatomy. Mr. Jolly has been appointed surgeon to the General Hospital; and Mr. John Clay obstetric surgeon to the Queen's Hospital.

In the Bristol Medical School, Mr. Tibbits has retired from the lectureship on Anatomy, and has taken the place of Mr. Crosby Leonard as lecturer on Surgery in conjunction with Mr. Coe. Mr. E. C. Board has become lecturer on Anatomy in place of Mr. Tibbits; and is succeeded as lecturer on Forensic Medicine by Mr. Keall. Dr. E. Ludlow has been appointed assistant-physician, and Mr. Board assistant-surgeon, to the Royal Infirmary.

In the Leeds School of Medicine, Mr. Wright and Mr. Walker succeed Mr. Hall and Mr. Jessop as lecturers on Physiology. Mr. S. Hey retires from the lectureship on Surgery; and Mr. Jessop is appointed one of the lecturers. Mr. J. A. Nunneley gives instruction in Aural Diseases. Dr. Chadwick has resigned the post of physician to the Infirmary and has been appointed consulting-physician; Dr. J. E. Eddison has been appointed physician.

Dr. Caton has been appointed demonstrator of Practical Physiology in the Liverpool Royal Infirmary School of Medicine. Dr. Inman has resigned the office of physician to the Liverpool Royal Infirmary, and has been succeeded by Dr. Waters.

In consequence of the death of Mr. Dumville, Mr. Bowring, lately dispensary surgeon, has become full surgeon to the Manchester Royal Infirmary.

In the University of Durham College of Medicine at Newcastle, Dr. Arnison lectures (in conjunction with Dr. Humble) on *Materia Medica* in place of Botany.

#### OPENING OF THE MEDICAL SCHOOLS.

THE subjoined is a list of the Medical Schools in England and Scotland, with the date of their opening, and the names of the gentlemen appointed to deliver introductory addresses. Where no name is inserted, it is to be understood that there is no special introductory lecture.

St. Bartholomew's Hospital—October 2nd.  
 Charing Cross Hospital—Dr. Green—October 2nd, 8 P.M.  
 St. George's Hospital—Dr. John Clarke—October 2nd, 2 P.M.  
 Guy's Hospital—Dr. Oldham—October 2nd, 2 P.M.  
 King's College—Dr. Rutherford—October 2nd, 4 P.M.  
 London Hospital—Dr. Little—October 2nd, 3 P.M.  
 St. Mary's Hospital—Dr. A. Meadows—October 2nd, 8 P.M.  
 Middlesex Hospital—Dr. John Murray—October 2nd, 3 P.M.  
 St. Thomas's Hospital—Mr. Le Gros Clark—October 2nd, 2 P.M.  
 University College—Dr. Charlton Bastian—October 2nd, 3 P.M.  
 Westminster Hospital—Dr. Basham—October 2nd, 8 P.M.  
 Bristol Medical School—October 2nd.  
 Birmingham (Queen's College)—Dr. Russell—October 3rd, 3 P.M.  
 Leeds School of Medicine—Dr. Clifford Allbutt—Oct. 2nd, 12 noon.  
 Liverpool Royal Infirmary School of Medicine—Dr. W. Carter—October 2nd, 3 P.M.  
 Manchester Royal School of Medicine—Mr. R. T. Hunt, October 2nd, 12 noon.  
 Newcastle College of Medicine—Dr. Phillipson—October 2nd, 2 P.M.  
 Sheffield School of Medicine—Mr. A. Allen—October 2nd.  
 Aberdeen University—November 1st.  
 Edinburgh University—Sir A. Grant, Bart., LL.D.—November 1st.  
 Edinburgh School of Medicine—Mr. Annandale—November 1st, 11 A.M.  
 Glasgow University—Dr. Dickson—October 31st.  
 " Anderson's University—October 31st.  
 The Dublin Medical Schools open their Dissecting-Rooms on October 1st, but lectures do not begin until the end of the month.

## REGULATIONS

OF

THE GENERAL MEDICAL COUNCIL AND  
MEDICAL LICENSING BODIES.

SESSION 1871-72.\*

## THE GENERAL MEDICAL COUNCIL.

*Recommendations and Opinions on Preliminary Examination.*

THAT Testimonials of Proficiency granted by the National Educational Bodies, according to the subjoined list, may be accepted, the Council reserving the right to add to, or take from, the list. I.—*Universities of the United Kingdom.* Oxford: Examination for a Degree in Arts; Responsions; Moderations; Local Examinations (Senior), Certificate to include Latin and Mathematics. Cambridge: Examination for a Degree in Arts; Previous Examination; Local Examinations (Senior), Certificate to include Latin and Mathematics. Durham: Examinations for a Degree in Arts; Examination for Students in their Second and First years; Registration Examination for Medical Students; Local Examinations (Senior), Certificate to include Latin and Mathematics. London: Examination for a Degree in Arts; Matriculation Examination. Aberdeen, Edinburgh, Glasgow, or St. Andrew's: Examination for a Degree in Arts; Preliminary Examination for Graduation in Medicine or Surgery. Edinburgh: Examination of (Senior) Candidates for Honorary Certificates under the Local Examinations of the University of Edinburgh. Dublin: Examination for a Degree in Arts; Entrance Examination. Queen's University (Ireland): Examination for a Degree in Arts; Entrance Examination; Examination for the Diploma of Licentiate in Arts; Previous Examination for B.A. Degree. II.—*Other Bodies named in Schedule (A) to the Medical Act.* Royal College of Surgeons of England: Examination conducted, under the superintendence of the College of Surgeons, by the Board of Examiners of the Royal College of Preceptors. Society of Apothecaries of London: Examination in Arts. Royal College of Physicians, Edinburgh, and Royal College of Surgeons, Edinburgh: Preliminary Examination in General Education, conducted by a Board appointed by these two Colleges combined. Faculty of Physicians and Surgeons of Glasgow: Preliminary Examination in General Literature. Royal College of Surgeons in Ireland: Preliminary Examination, Certificate to include Mathematics. Apothecaries' Hall of Ireland: Preliminary Examination in General Education. III.—*Examining Bodies in the United Kingdom, not included in Schedule (A) to the Medical Act.* Royal College of Preceptors: Examination for a First Class Certificate. The Examiners for Commissions in the Military and Naval Services of the United Kingdom: Certificate to include all the subjects required by the General Medical Council. IV.—*Colonial and Foreign Universities and Colleges.* University of Calcutta, Madras, or Bombay: Entrance Examination, Certificate to include Latin. University of McGill College, Montreal, of Toronto, of King's College, Toronto, of Queen's College, Kingston, of Victoria College, Upper Canada, of Fredericton, New Brunswick, or of Sydney: Matriculation Examination. University of King's College, Nova Scotia: Matriculation Examination; Responsions. University of Melbourne: Matriculation Examination, Certificate to include all the subjects required by the General Medical Council. Codrington College, Barbadoes: English Certificate for Students of two years' standing, specifying the subjects of Examination; Latin Certificate, or "Testamur." Tasmanian Council of Education: Examination for the Degree of Associate of Arts, Certificate to include Latin and Mathematics. Christ's College, Canterbury, New Zealand: Voluntary Examinations, Certificate to include all the subjects required by the General Medical Council. Cape of Good Hope: Third Class Certificate in Literature and Science, granted by the Board of Public Examiners.—N.B. A Degree in Arts of any University of the United Kingdom, or of the Colonies, or of such other Universities as may be specially recognised from time to time by the Medical Council, is considered a sufficient Testimonial of Proficiency.—That it be recommended to the Licensing Boards not to accept the certificate of proficiency in general (preliminary) education from any of the Bodies, the names of which are contained in the list annually circulated, unless such certificate testify that the student to whom it has been granted has been examined in—I. English Language, including Grammar and Com-

position.\* 2. Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations. 3. Geometry: First Two Books of Euclid. 4. Latin, including Translation and Grammar. And in one of the following *Optional Subjects*:—Greek; French; German; Natural Philosophy, including Mechanics, Hydrostatics, and Pneumatics.—That students who cannot produce any of the testimonials referred to in the first recommendation be required to pass an Examination in Arts, established by any of the bodies named in Schedule (A) to the Medical Act, and approved by the General Medical Council.—That certificates of proficiency, to be received from all bodies legally authorised to examine in General Education in Great Britain and Ireland, and from the several Licensing Bodies enumerated in Schedule (A) to the Medical Act in Great Britain and Ireland, shall bear evidence that the candidates have been examined and approved in at least the above subjects.—That, in the case of certificates received from similar educational and licensing bodies in other parts of the empire and foreign countries, satisfactory evidence shall be given to the Medical Council, or Branch Councils, that such certificates are equivalent to those recognised in the United Kingdom.—That it shall be delegated to the Executive Committee to prepare annually and lay before the Council for recognition a list of Examining Bodies, whose examinations shall fulfil the conditions of the Medical Council as regards Preliminary Education.

*Registration of Medical Students.*

Every medical student shall be registered in the manner prescribed by the General Medical Council.—No medical student shall be registered until he has passed a Preliminary Examination.—The commencement of the course of Professional Study recognised by any of the qualifying bodies, shall not be reckoned as dating earlier than fifteen days before the date of registration.—The registration of medical students shall be placed under the charge of the Branch Registrars.—Each of the Branch Registrars shall keep a Register of medical students according to a form, containing the Date of Registration, the Name, the Preliminary Examination and Date, and the Place of Medical Study.—Every person desirous of being registered as a medical student, shall apply to the Branch Registrar of the division of the United Kingdom in which he is residing, according to the annexed form,† which may be had on application to the several qualifying bodies, medical schools, and hospitals; and shall produce or forward to the Branch Registrar a certificate of his having passed a preliminary examination, as required by the General Medical Council, and a statement of his place of medical study.—The Branch Registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration.—Each of the Branch Registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students.—The several Branch Councils shall have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory.—A copy of the Register of Medical Students, prepared by each of the Branch Registrars, shall be transmitted, on or before the 31st December in each year, to the Registrar of the General Council; who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an Alphabetical List of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule (A) to the Medical Acts, and through the Branch Registrars to the several medical schools and hospitals.—The several qualifying bodies are recommended not to admit, after October, 1870, to the final examination for a qualification under the Medical Acts, any candidate (not exempted from registration) whose name had not been

\* The General Medical Council will not consider any examination in English sufficient that does not fully test the ability of the candidate.—1. To write a few sentences in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition. 2. To write a portion of an English author to dictation. 3. To explain the grammatical construction of one or two sentences. 4. To point out the grammatical errors in a sentence ungrammatically composed, and to explain their nature. 5. To give the derivation and definition of a few English words in common use. Provided always that an examination may be accepted as satisfactory that secures, on the part of the candidate passing it, a sufficient grammatical knowledge of English.

† *Form of Application for Registration as a Medical Student.*—I hereby apply to be registered as a Student in Medicine, in conformity with the Regulations of the General Council of Medical Education and Registration of the United Kingdom, for which purpose I submit the following particulars. [Name of applicant (to be written in words at length); Surname; Christian name; Preliminary examination; Date of preliminary examination; Place of medical study; Applicant's signature; Address; and Date of application. To the Registrar of the Branch Council for —.]

N.B.—The above Form of Application, duly and legibly filled up, must be forwarded to the Registrar, post free, and be accompanied by a Certificate of the applicant's having passed a Preliminary Examination, as required by the General Medical Council, and a statement of his place of Medical Study.

\* To save space, we omit those portions of the Recommendations of the General Medical Council and of the Regulations of the Examining Bodies, which are not of direct importance to medical students.

entered in the Medical Students' Register at least four years previously.—In the case of candidates from other than schools of the United Kingdom, the Branch Councils shall have power to admit exceptions to this recommendation.

#### *Age for Licence to Practise.*

That the age of 21 be the earliest age at which a candidate for any Professional Licence shall be admitted to his final examination; that the age shall, in all instances, be duly certified; and that a return of any exceptions to this recommendation allowed by the Licensing Bodies, together with the reasons for such exceptions, be transmitted to the Branch Council of that part of the United Kingdom in which they have been granted.—That no Licence be obtained at an earlier period than after the expiration of forty-eight months subsequent to the registration of the candidate as a medical student.

#### *Professional Education.*

That the course of Professional Study required for a Licence shall comprehend attendance during not less than four winter sessions, or three winter and two summer sessions, at a school recognised by any of the Licensing Bodies mentioned in Schedule (A) to the Medical Act.—That the following are the subjects without a knowledge of which no candidate should be allowed to obtain a qualification entitling him to be registered:—1. Anatomy; 2. General Anatomy; 3. Physiology; 4. Chemistry; 5. Materia Medica; 6. Practical Pharmacy; 7. Medicine; 8. Surgery; 9. Midwifery; 10. Forensic Medicine. "Chemistry" should include a knowledge of the principles of Chemistry, and of those details of the science which bear on the study of Medicine. "Medicine and Surgery" should include a knowledge of systematic and Clinical Medicine and Surgery, and also of Morbid Anatomy.—That it be recommended to the several Licensing Bodies that the courses of instruction required by them be framed in such a manner as to secure a due share of attention, both to preparatory branches and to those more strictly connected with the practice of medicine and surgery; and that it be suggested accordingly to these bodies, that their regulations should be such as to prevent attendance upon lectures from interfering with hospital and clinical study.—That the Council will view with approbation any encouragement held out by the Licensing Bodies to students to prosecute the study of the natural sciences before they engage in studies of a strictly professional character.

#### *Professional Examination.*

That it is desirable that the different Licensing Bodies should combine their examinations, when this is practicable, so as to secure that the knowledge of every practitioner whose name appears on the Register shall have been tested in all the subjects of professional education which the Council has determined to be essential, as above enumerated.—That the professional examination for any Licence be divided into two parts; the first embracing the primary or fundamental branches directly connected with the Practice of Medicine and Surgery. That the former be not undergone till after the close of the winter session of the second year of professional study; and the latter, or final examination, not till after the close of the prescribed period of professional study.—That the examination in Physics, Botany, and Natural History may be undergone at an earlier period than the first professional examination.—That the professional examinations be conducted both in writing and orally; and that they be practical in all branches in which they admit of being so.—That not less than two examiners, or one examiner with an assessor, should be present at every oral examination.—That the oral examinations should be so far public as to be open at least to the medical and surgical graduates, or members of the examining body.—That the questions to be answered in writing should be so numerous, and embrace such a variety of the details of each subject, as may adequately test the proficiency of the candidate; and that they should be submitted to the whole body of examiners for consideration and revision, if desirable, before being proposed to the candidates.—That the written answers should be submitted to more than one of the examiners.—That excellence in one or more subjects should not be allowed to compensate for failure in others.—That if a candidate be rejected for failure in any one subject, he should be re-examined in all.—That examiners should only be elected for definite periods, with power of reappointment.—That the professional examinations be held by the several Licensing Bodies, except in special cases, at stated periods, to be publicly notified.—That returns from the Licensing Bodies in Schedule (A) be made annually, on January 1st, to the General Medical Council, stating the number and names of the candidates who have passed their first as well as their second and third examinations, and the number of those who have been rejected at the first and second and third examinations respectively.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.\*

#### EXTRACTS OF BYE-LAWS RELATING TO MEMBERS.

Any person who shall have satisfied the College touching his acquirements in general Science and Literature, and his knowledge of Medicine, Surgery, and Midwifery, and who shall comply with the Bye-Laws and Regulations of the College, may be proposed to the College to be admitted a Member. Every Candidate for the Membership who shall have commenced his professional studies after September 1861, shall satisfy the Censor's Board that previously to the commencement of his professional studies he has obtained a Degree in Arts from some University of the United Kingdom or of the Colonies, or from some other University specially recognised by the Medical Council, or that he has passed examinations equivalent to those required for a Degree in Arts. Every Candidate for membership shall furnish proof that he has attained the age of 25; and shall produce a testimonial of moral character and conduct from a Fellow or Member of the College.—Every Candidate (*except such as are specially exempted as below described*) shall produce proof of his having been engaged in professional studies during five years, of which four years at least shall have been passed at a medical school or schools recognised by the College; and shall produce evidence, satisfactory to the Censors' Board, of having studied the following subjects. [The subjects are the same as those required for the Licence (see next page); but Morbid Anatomy must be attended during six months, and Clinical Medicine during *three winter and three summer sessions*.] He must also give evidence of having attended diligently during three winter sessions and three summer sessions the medical practice, and *during three winter sessions and two summer sessions the surgical practice*, of an hospital containing at least 100 beds; of having been engaged during six months in the clinical study of Diseases peculiar to Women; and of having served the office of clinical clerk in the medical wards during at least six months.—Every candidate who has prosecuted his studies abroad, whether in part or to the full extent required by the preceding bye-law (*except such as shall be exempted as below stated*), shall, nevertheless, bring proof of his having attended, during at least twelve months, the medical practice of an hospital in the United Kingdom containing at least 100 beds.—If the Censors' Board doubt the sufficiency of the certificates and testimonials produced by any candidate, or his fitness for admission to examination, they may submit the case to a general meeting of the Fellows.—No candidate shall be admitted to examination who is engaged in trade; or who dispenses medicine, or makes any engagement with a chemist, or any other person, for the supply of medicines; or who practises medicine or surgery in partnership by deed or otherwise, so long as that partnership continues; or who refuses to make known, when required by the President and Censors, the nature and composition of any remedy he uses.—Every candidate (*except in cases specially exempted*) shall give proof of his acquirements by written answers to questions, and shall be examined *vivâ voce* at three separate examinations, and shall be approved by the President and Censors, or by the major part of them.

*Exemptions.*—Any candidate who has already obtained the degree of Doctor or Bachelor of Medicine at an University in the United Kingdom, wherein the courses of study, and the examinations to be undergone by the students previously to graduation, shall have been adjudged by the Censors' Board to be entirely satisfactory, shall be exempt (if the Censors shall think fit) from all or any part of the examinations hereinbefore described, except such as relate to the third or pass examination; the nature and extent of which examination shall, in the case of each candidate, be determined by the Censors' Board. Every candidate for the membership will, however, be required to translate into English a passage from a Latin author, and he will have the opportunity of showing a knowledge of Greek, or of one or more of the modern European languages.—If any candidate who has attained the age of 40 years shall produce testimonials satisfactory as to his moral character and conduct and his general and professional acquirements, further showing that he has improved the art or extended the science of Medicine, or has at least distinguished himself highly as a medical practitioner; the Censors' Board, having well considered these testimonials, may, if they see fit, submit them to the Fellows at a general meeting, and it shall be determined by the votes of the Fellows present, or of the majority of them, taken by ballot, whether the candidate shall be admitted to examination, which shall, in every such case, be as full and complete as the Censors may deem sufficient.—Any candidate who shall produce satisfactory evidence of having passed an

\* The requirements printed in italics apply to candidates who commence their Professional Education in the United Kingdom on or after October 1st, 1867; and to candidates who commence their Professional Education at a recognised Foreign or Colonial School on or after October 1st, 1868.

examination on Anatomy and Physiology, conducted by any of the bodies named in Schedule (A) to the Medical Act, and recognised as requiring a course of study and an examination satisfactory to the College, will be exempt from re-examination on the subjects of the primary examination.—Any candidate who shall have obtained a degree in Surgery at an University in the United Kingdom, or who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy, and on the Principles and Practice of Surgery.

Every candidate approved by the Censors' Board, shall be proposed, at the next general meeting of Fellows, as qualified to become a Member of the College; and if the majority of the Fellows present shall consent, he shall, on complying with the regulations prescribed by the bye-laws, be admitted a Member. The Fee for admission shall be Thirty Guineas.

Every candidate for the Membership of the College (except such as shall be exempted as above stated), will be required to pass the following examinations.

The First Examination, on Anatomy and Physiology, will be conducted on successive days as follows. First Day: *Evening*, from seven to ten, by written questions. Second Day: *Evening*, commencing at seven o'clock, *vivâ voce*, on Dissections and Preparations.

The Second Examination will be conducted on successive days, as follows. First Day: *Evening*, from seven to ten, by written questions on Surgical Anatomy, and on the Principles and Practice of Surgery. Second Day: *Morning*—The candidate's practical knowledge will be tested, either at the College or in the surgical wards of a Hospital. *Afternoon*, from one to four, on Materia Medica, and on Chemistry in its applications to Pathology, Pharmacy, and Toxicology.\* (This examination will be conducted partly by written questions and partly in a practical manner.) *Evening*, commencing at seven o'clock, by written questions on Midwifery and the Diseases Peculiar to Women.

The Third, or Pass Examination, will be conducted on successive days as follows. First Day: *Afternoon*, from two to six, by written questions on Medical Anatomy and on the Principles of Medicine. Second Day: *Afternoon*, from two to six, by written questions on the Practice of Medicine, including the *Principles of Public Health*, and on Psychological Medicine. Third Day: The candidate's practical knowledge will be tested, either at the College or in the medical wards of a Hospital. Fourth Day: *Afternoon*, commencing at three o'clock, *vivâ voce*, on Medical Anatomy, and on the Principles and Practice of Medicine.

Candidates will not be admitted to the first examination until after the termination of the second winter session of professional study at a recognised medical school, nor to the second examination until after the termination of four years of professional study, nor to the third or pass examination until after the completion of the required course of professional study.—Any candidate who shall be rejected at the first examination, will not be readmitted to examination until after the lapse of three months, and will be required to produce a certificate of the performance of dissections, or other professional study, satisfactory to the examiners, during that time.—Any candidate who shall be rejected at the second examination, will not be readmitted to examination until after the lapse of six months, and will be required to produce a certificate of attendance on the practice of a recognised Hospital during that time, and also of attendance on Clinical Lectures.—Any candidate not approved by the Censors' Board at the third or pass examination, will not (except by special permission of the College) be readmitted to examination until after the lapse of a year.—Every candidate must give fourteen days' notice in writing to the Registrar of the College, of his intention to present himself for examination, at the same time transmitting the following certificates. *For the Primary Examination*: Evidence of having passed an Arts Examination; and, in the case of those who shall have commenced professional studies after 1861, evidence of having previously obtained a Degree of Arts from some University of the United Kingdom, or of the Colonies, or from some other University specially recognised by the Medical Council, or that he has passed examinations equivalent to those required for a Degree in Arts; of having been duly registered as a medical student; and of having completed the second winter session of professional study at a recognised medical school. *For the Second Examination*: Evidence of having completed four years of professional study; of having attained the age of 21 years; of instruction and proficiency in the prac-

tice of vaccination; and of having attended not less than twenty labours. *For the Pass Examination*: Proof of having attained the age of 25 years; a testimonial from a Fellow or Member of the College; evidence of having completed the required course of professional study.

Blank forms of the required certificates of attendance on hospital practice and on lectures may be obtained on application at the college.

Examinations of Candidates for the Membership of the College will take place in 1872 as follows. *First Examination*, commencing on Mondays, February 5th, April 1st, July 1st, October 7th, December 2nd. *Second Examination*, commencing on Mondays, February 12th, April 8th, July 8th, October 14th, December 9th. *Third, or Pass Examination*, commencing on Thursday, January 18th, April 18th, July 18th, October 19th.

#### BYE-LAWS RELATING TO LICENTIATES.

Every candidate for the College Licence (except when otherwise provided by the bye-laws) is required to produce satisfactory evidence to the following effect.—Of having attained the age of 21 years.—Of moral character.—Of having passed, before the commencement of professional study, an examination in the subjects of general education recognised by the College.—Of having been registered as a medical student in the manner prescribed by the General Medical Council.—Of having been engaged in professional studies during four years, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions, in one or other of the following ways: 1. Attending the practice of a hospital or other institution recognised by the College; 2. Receiving instruction as the pupil of a legally qualified practitioner, holding any public appointment which affords opportunities, satisfactory to the examiners, of imparting a practical knowledge of Medicine, Surgery, or Midwifery; 3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction.\*—*Of having attended, during three winter sessions and two summer sessions, the Medical and Surgical Practice at a recognised Hospital or Hospitals, and of having been engaged during six months in the clinical study of Diseases peculiar to Women.*—Of having studied the following subjects: Anatomy (with Dissections), two winter sessions;† Physiology, two winter sessions; Chemistry, six months; Practical Chemistry, three months; Materia Medica, three months; Practical Pharmacy, three months;‡ Botany, three months;§ Morbid Anatomy, two winter sessions;|| Principles and Practice of Medicine, two winter sessions;¶ Principles and Practice of Surgery, two winter sessions; \*\* Clinical Medicine, and Clinical Surgery, each two winter sessions and two summer sessions;†† Midwifery and Diseases peculiar to Women, three months;‡‡ Forensic Medicine, three months.—Of having passed the professional examination.

#### Examination for the Licence.

Every candidate for the Licence, before he is admitted to examination, will be required to sign a declaration, stating whether he has or has not been rejected within three months by any of the Examining Boards included in Schedule (A) to the Medical Act.

The first examination, and the second examination as far as the end of the second day, are conducted at the same hours and on the same subjects as the first and second examinations for the membership. The remainder of the examination is as follows, Third day: *Evening*, from seven to ten, by written questions on Medical Anatomy, and on the Principles and Practice of Medicine, including the Principles of Public Health. Fourth day: *Morning*—The candidate's practical knowledge will be tested, either at the College or in the medical wards

\* Professional studies commenced before the candidate shall have passed an examination in the subject of general education, will not be recognised by the College.

† The winter session comprises a period of six months, and the summer session a period of three months.

‡ By Practical Pharmacy is meant instruction in the Laboratory of a Registered Medical Practitioner, or of a Member of the Pharmaceutical Society of Great Britain, or of a Public Hospital or Dispensary recognised by the College.

§ This course of lectures may be attended prior to the commencement of professional studies; and any candidate producing satisfactory evidence that Botany formed one of the subjects of his preliminary examination, will be exempt from attendance on this course.

|| This includes attendance and instruction in the *Post Mortem* Room during the period of Clinical Study.

¶ It is required that the Principles of Public Health should be comprised in this course of lectures, or in the course of lectures on Forensic Medicine.

\*\* The attendance on the lectures on Medicine and Surgery must not commence earlier than the second winter session at a recognised medical school.

†† The attendance on the lectures on Clinical Medicine and Clinical Surgery must not commence until after the first winter session at a recognised medical school. By Clinical Medicine and Clinical Surgery are meant special study and instruction at the bedside, with lectures on cases.

‡‡ Certificates must also be produced of attendance on not less than twenty Labours, and of instruction and proficiency in Vaccination.

\* Candidates who shall have passed the first examination for the Licence at this College before October 1st, 1867, are exempted from re-examination on Materia Medica, and on Chemistry in its application to Pharmacy.

of a Hospital. *Evening*, commencing at seven o'clock, *viva voce*, on the Principles and Practice of Medicine, Surgery, and Midwifery.

Candidates will not be admitted to the first examination until after the termination of the second winter session of professional study at a recognised medical school, nor to the second or pass examination until after the termination of four years of professional study. The College will not admit to the pass examination any candidate (not exempted from registration) whose name had not been entered in the Medical Students' Register at least four years previously.

Any candidate who shall be rejected at the first examination, will not be re-admitted to examination until after the lapse of three months, and will be required to produce a certificate of the performance of Dissections, or other professional study satisfactory to the examiners, during that time. Any candidate who shall be rejected at the second or pass examination, will not be re-admitted to examination until after six months, and will be required to produce a certificate of attendance on the practice of a recognised Hospital during that time, and also of attendance on Clinical Lectures.

Every candidate intending to present himself for examination, is required to give fourteen days' notice in writing to the Registrar of the College, at the same time transmitting the following certificates. *For the First Examination*—Evidence of having passed an Arts Examination; of having been duly registered as a medical student; and of having completed the second winter session of professional study at a recognised medical school. *For the Second, or Pass Examination*—Evidence of having completed four years of professional study: of having attained the age of 21 years; of proficiency in the practice of vaccination; and of having attended not less than twenty labours. A testimonial of moral character is required of every candidate. Blank forms of the required certificates of attendance on hospital practice and on lectures may be obtained on application at the College.

The exemptions in the regulations regarding the Membership, are applicable also to candidates for the Licence; and any candidate who shall have obtained a Degree in Medicine at an University recognised by the College, after a course of study and examination satisfactory to the College, shall be exempt from re-examination on the subjects of the primary examination.—Any Registered Medical Practitioner, whose qualification or qualifications shall have been obtained before the 1st day of January, 1861, having been, with the consent of the College, admitted a candidate for the Licence, will be examined on the Principles and Practice of Medicine, Surgery, and Midwifery; but he will be exempted from such other parts of the professional examination as his qualifications may seem to the examiners to render in his case unnecessary.\*

The fee for the Licence is Fifteen Guineas, of which Five Guineas are to be paid on admission to the first examination, which fee will not be returned to any candidate rejected at this examination, but will be allowed in the fee for the Licence; and he will be admitted to one subsequent first examination without the payment of an additional fee.† Any candidate who shall be rejected at the second or pass examination will have the fee, paid on admission to this examination, returned to him, less Three Guineas.

Licentiates of this College shall not compound or dispense medicines except for patients under their own care.

Examinations of candidates for the College Licence will take place as follows. *First Examination*, commencing on the first Mondays of February, April, July, October, and December. *Second, or Pass Examination*, commencing on the second Mondays of the same months.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### REGULATIONS RESPECTING THE DIPLOMA OF MEMBER.

#### Section I.—Preliminary General Education and Examination.

Candidates who commenced their professional education on or after the 1st of January, 1861, will be required to produce one or other of the following certificates:—1. Of Graduation in Arts at an University recognised for this purpose; viz., Oxford; Cambridge; Dublin; London; Durham; Queen's University in Ireland; Edinburgh; Glasgow; Aberdeen; St. Andrew's; Calcutta; Madras; Bombay; McGill College, Montreal; and Queen's College, Kingston, Canada. 2. Of having passed an examination for Matriculation, or such other examination as shall, in either case, from time to time be sanctioned by the Council of this College, at an University in the United Kingdom, or at a Colonial or

Foreign University recognised by the Council of this College.\* 3. Of having passed the preliminary examination for the Fellowship of this College. 4. Of having passed the preliminary examination of the Royal Colleges of Surgeons in Ireland or of Edinburgh, or of the Faculty of Physicians and Surgeons of Glasgow. 5. Of having passed the examination in Arts of the Society of Apothecaries of London, or of the Apothecaries' Hall of Ireland. 6. Of having passed the first-class examination of the Royal College of Preceptors. 7. Testamur of the Codrington College, Barbadoes. 8. Degree of Associate of Arts granted by the Tasmanian Council of Education, with a certificate that the student has been examined in Latin and Mathematics. 9. Of having passed the voluntary examinations of Christ's College, Canterbury, New Zealand, the certificate to include all the subjects required from time to time in the Preliminary Examination of the College. Candidates who shall not be able to produce one or other of the foregoing certificates, will be required to pass an examination in English, Classics, and Mathematics, conducted by the Board of Examiners of the Royal College of Preceptors, under the direction and supervision of this College.†

#### Section II.—Professional Education.

Professional studies prior to the date at which the candidate shall have passed an examination in general knowledge, in conformity with the regulation in the preceding section, are not recognised.—The following will be considered as the commencement of professional education:—1. Attendance on the practice of a hospital, or other public institution recognised by this College; 2. Instruction as the pupil of a legally qualified surgeon, holding the appointment of Surgeon to a Hospital, General Dispensary, or Union Workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council; 3. Attendance on lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College. *The commencement of professional study otherwise than by attendance on lectures in recognised Medical Schools, or by attendance on the practice of recognised Hospitals, will not be admitted until a certificate thereof shall be furnished to the Secretary for registration at the College, by the practitioner whose pupil the candidate shall have become, or by the medical superintendent of the Hospital or other institution to the practice of*

\* The following are the examinations at present recognised under this Clause (No. 2), viz.: Oxford—Responsions or Moderations; Middle-Class Examinations, Senior, the Certificates to include Latin and Mathematics. Cambridge—Previous Examination; Middle-Class Examinations, Senior, the Certificates to include Latin and Mathematics. Dublin—Entrance Examination. London—Matriculation Examination. Durham—Examination of Students in Arts in their second and first years; Middle-Class Examinations, Senior, the Certificates to include Latin and Mathematics; Registration Examination for Medical Students. Queen's University in Ireland—Two years' Arts Course for Diploma of Licentiate in Arts; Preliminary Examinations at end of B.A. Course; Middle-Class Examinations, the Certificates to include Latin and Mathematics; Matriculation Examinations. Edinburgh, Aberdeen, Glasgow, and St. Andrew's—Preliminary or Extra Professional Examinations for Graduation in Medicine. Calcutta, Madras, and Bombay—Matriculation Examinations. Canada: McGill College, Montreal; University College, Toronto; Queen's College, Toronto; University of Laval, Quebec—Matriculation Examinations. Queen's College, Kingston—Matriculation Examination; Preliminary Examination of Students in Medicine. University of Melbourne—Matriculation Examination, with a Certificate that the Student has passed an Examination in Latin.—Sydney—Matriculation Examination.—New York, Bellevue Hospital Medical College—Matriculation Examination.

† The following are the subjects of the examination during the year: viz.—Part I. *Compulsory Subjects*. 1. Reading aloud a passage from some English author. 2. Writing from dictation. 3. English Grammar. 4. Writing a short English composition: such as a description of a place, an account of some useful or natural product, or the like. 5. Arithmetic. No candidate will be passed who does not show a competent knowledge of the first four rules, simple or compound, of Vulgar Fractions, and of Decimals. 6. Questions on the Geography of Europe, and particularly of the British Isles. 7. Questions on the outlines of English History; that is, the succession of the Sovereigns and the leading events of each reign. 8. Mathematics: Euclid, Books I and II; Algebra to Simple Equations inclusive. 9. Translation of a passage from the second book of Caesar's *Commentaries De Bello Gallico*. Part II. *Optional Subjects*. Papers will also be set on the following six subjects; and each candidate will be required to offer himself for examination on one subject at least, at his option; but no candidate will be allowed to offer himself for examination on more than four subjects:—1. Translation of a passage from the first Book of the *Anabasis* of Xenophon. 2. Translation of a passage from X. B. Santini's *Psichica*. 3. Translation of a passage from Schiller's *Wallenstein*. Besides these translations into English, the candidate will be required to answer questions on the grammar of each subject, whether compulsory or optional. 4. Mechanics: the questions will be chiefly of an elementary character. 5. Chemistry: the questions will be on the elementary facts of Chemistry. 6. Botany and Zoology: the questions will be on the Classification of Plants and Animals. The quality of the handwriting and the spelling will be taken into account. N.B. Each candidate who has not already paid the amount is required to pay a Fee of £2 on the morning of the first day of the examination, prior to his admission thereto. The next examination will be held on or about the third Tuesday of Wednesday in December. The exact dates of the examination are duly advertised when fixed in the Medical Journals; and candidates are required to send in the prescribed forms of application not less than three weeks before the commencement of each examination. Notice. A candidate, in order to qualify for the Fellowship, is required, in addition to the subjects included in Part I, to pass in Greek, French, or German; and in one, at his option, of the remaining subjects in Part II.

\* Forms of application may be obtained of the Registrar of the College.

† The Fee must be paid within three days prior to the day on which the examination commences.

which he shall have entered, and will date only from the reception of such certificate by the Secretary; the certificate to be accompanied by proof of having passed the preliminary examination in general knowledge.—Candidates will be required to produce certificates:—1. Of being 21 years of age. 2. Of having been engaged, subsequently to passing the preliminary examination, during four years, or during not less than four winter and four summer sessions, in the acquirement of professional knowledge. 3. Of having attended the following courses: Lectures on Anatomy, two winter sessions. 4. Dissections, not less than two winter sessions. 5. Lectures on General Anatomy and Physiology, one winter session. 6. Practical General Anatomy and Physiology during another winter or a summer session, consisting of not less than thirty meetings of the class.\* 7. Lectures on Surgery, one winter session. 8. Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by Clause 7.† 9. One Course of Lectures on each of the following subjects, viz.: Chemistry;‡ Materia Medica; Medicine; Forensic Medicine; Midwifery (with practical instruction, and a certificate of having personally conducted not less than ten labours); Pathological Anatomy during not less than three months. 10. Practical Pharmacy, three months. 11. A three months' course of Practical Chemistry (with manipulations), in its application to medical study. 12. Instruction and proficiency in the practice of Vaccination.§ 13. Of having attended, at a recognised hospital or hospitals, the practice of Surgery during three winter|| and two summer¶ sessions. 14. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher, during not less than three months.\*\* 15. Of having, subsequently to the first winter session of attendance on Surgical Hospital Practice, attended, at a recognised hospital or hospitals, Clinical Lectures on Surgery during two winter and two summer sessions. 16. Of having been a dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a Surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of Practical Surgery. 17. Of having attended, during the whole period of attendance on Surgical Hospital Practice (see clause 13), demonstrations in the *post mortem* rooms of a recognised hospital. 18. Of having attended, at a recognised hospital or hospitals, the Practice of Medicine and Clinical Lectures on Medicine during one winter and one summer session.

NOTICE.—Clauses 6, 8, 11, 14, and 17, and the notes to clauses 6, 8, 9, 12, and 14, together with the courses of lectures on Forensic Medicine and Pathological Anatomy mentioned in Clause 9, are applicable to candidates who commenced their professional education on or after the 1st of October, 1870.

N.B.—Blank forms of the required certificates may be obtained on application to the Secretary, and all necessary certificates will be retained at the College.

### Section III.—Concerning Certificates, etc.

1. Certificates will not be received on more than one branch of science from one and the same lecturer; but Anatomy and Dissections will be

\* By the practical course referred to in Clause 6, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, etc.

† The course of Practical Surgery is intended to embrace instruction in which each pupil shall be exercised in practical details, such as in—the application of anatomical facts to Surgery, on the living person, or on the dead body; the methods of proceeding and the manipulations necessary in order to detect the effects of diseases and accidents, on the living person, or on the dead body; the performance, where practicable, of the operations of Surgery on the dead body; the use of Surgical Apparatus; the examination of diseased structures, as illustrated in the contents of a museum of Morbid Anatomy and otherwise.

‡ The course of lectures on Chemistry will not be required in the case of a candidate who shall have passed a satisfactory examination in this subject in his preliminary examination.

§ In the case of candidates who commenced their professional education on or after the 1st of October, 1868, the certificate of instruction in vaccination will only be received from recognised Vaccine Stations, or from recognised Vaccine Departments in Medical Schools or Hospitals, or other Public Institutions, where the appointed teacher of vaccination is not liable to frequent change, and where ample means for study are provided by not less than such a number of cases (eight or ten on an average weekly) as may be found, after due inquiry, to be sufficient for this purpose at each place.—The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

|| The Winter Session comprises a period of six months; and, in England, commences on the 1st of October and terminates on the 31st of March.

¶ The Summer Session comprises a period of three months; and, in England, commences on the 1st of May and terminates on the 31st of July.

\*\* It is intended that the candidate should receive the instruction required by Clause 14 at an early period of his attendance at the Hospital.

considered as one branch of science. 2. Certificates will not be recognised from any hospital in the United Kingdom, unless the surgeons thereto be members of one of the legally constituted Colleges of Surgeons in the United Kingdom; nor from any School of Anatomy and Physiology or Midwifery, unless the teachers in such school be members of some legally constituted College of Physicians or Surgeons in the United Kingdom; nor from any School of Surgery, unless the teachers in such school be members of one of the legally constituted Colleges of Surgeons in the United Kingdom. 3. No Metropolitan Hospital will be recognised by this College which contains less than 150, and no Provincial or Colonial Hospital which contains less than 100 patients. 4. The recognition of Colonial Hospitals and Schools is governed by the same regulations, with respect to number of patients and to courses of lectures, as apply to the recognition of Provincial Hospitals and Schools in England. 5. Certificates of attendance upon the practice of a recognised Provincial or Colonial Hospital unconnected with, or not in convenient proximity to, a recognised medical school, will not be received for more than one winter and one summer session of the hospital attendance required by the regulations of this College; and in such cases clinical lectures will not be necessary, but a certificate of having acted as dresser for the period of at least six months will be required. 6. Certificates will not be received from candidates who have studied in London, unless they shall have registered at the College their cards of admission to attendance on lectures and hospital practice within fifteen days from the commencement of the session; nor from candidates who have studied in the provincial schools in England, unless their names shall be duly returned from their respective schools.\* 7. Candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland, from candidates for their diploma. Candidates who shall have pursued the whole of their studies at recognised foreign or colonial Universities will be admitted upon the production of the several certificates required for their degree by the authorities of such Universities. 8. Members or Licentiates of any legally constituted College of Surgeons in the United Kingdom; Graduates in Surgery of any University recognised for this purpose by this College; and 9. Graduates in Medicine of any legally constituted College or University recognised for this purpose by this College, will be admitted to examination on producing their Diploma, Licence, or Degree, together with proof of being 21 years of age. In each of these cases, 7, 8, and 9, the candidate will also be required to produce a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the preliminary examination, at least four years, or a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

### Section IV.—Professional Examination.

This examination is divided into two parts. 1. The First or Primary Examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. 2. The Second or Pass Examination, on Surgical Anatomy and the Principles and Practice of Surgery and Medicine, is partly written, partly oral, and partly on the practical use of surgical apparatus and the practical examination of patients. [A candidate can claim exemption from examination in Medicine under the following conditions, viz.: a. The production by the candidate of a Degree, Diploma, or Licence in Medicine entitling him to register under the Medical Act of 1858, or a Degree, Diploma, or Licence in Medicine of a Colonial or Foreign University approved by the Council of the College. b. A declaration by the candidate, prior to his admission to the final examination for Membership or Fellowship, that it is his intention to obtain either of the medical qualifications mentioned in the foregoing paragraph; in which case the Diploma of the College will not be issued to him until he shall produce either the said medical qualification or proof of having passed the several examinations entitling him to receive the same.] 3. The primary examinations are held in January, April, May, July, and November, and the pass examinations generally in the ensuing week respectively. 4. Candidates will not be admitted to the primary examination until after the termination of the second winter session of attendance at a recognised school or schools; nor to the pass or surgical examination until after the termination of the fourth year of professional education. 5. The fee of Five Guineas, paid prior to the primary examination, and allowed on the whole fee of Twenty-

\* At their first registration in October, candidates will be required to produce a certificate of having passed one or other of the preliminary examinations in general knowledge recognised by this College.

two pounds\* payable for the diploma, is retained; and after any two consecutive failures at the primary examination, the candidate is required to pay an *additional* fee of Five Guineas prior to being again admitted to that examination, which *additional* fee is also retained. 6. Five guineas, part of the sum of sixteen pounds fifteen shillings, the balance of the whole fee due for the diploma and paid prior to the pass examination, is retained; and after any two consecutive failures at the pass examination, the candidate is required to pay an *additional* fee of five guineas prior to being again admitted to the said pass examination, which *additional* fee is also retained. 7. A candidate having entered his name for either the primary or pass examination, who shall fail to attend the meeting of the Court for which he shall have received a card, will not be allowed to present himself for examination within three months from the date at which he shall have so failed to attend. 8. A candidate referred on the primary examination is required, prior to his admission to re-examination, to produce a certificate of the performance of dissections during not less than three months subsequently to the date of his reference. 9. A candidate referred on the pass examination is required, prior to his admission to re-examination, to produce a certificate of at least six months' further attendance on the Surgical Practice of a recognised hospital, together with Lectures on Clinical Surgery, subsequently to the date of his reference.

#### REGULATIONS RELATING TO THE DIPLOMA OF FELLOW.

##### Section I.—Preliminary Examination.

Candidates must produce certificates of graduation in Arts at an University recognised for this purpose;† or of having passed such examinations in Arts as shall from time to time be required for graduation in Medicine at Oxford, Cambridge, Dublin, London, or Durham. Candidates who shall not be able to produce one or other of the foregoing certificates will be required to pass an examination conducted by the Board of Examiners of the Royal College of Preceptors.‡

##### Section II.—Professional Education.

I. Except in the cases provided for to the contrary, every candidate for admission to the First or Anatomical and Physiological Examination for the Fellowship is required to produce, in addition to certificates of the same kind as are described in Section II, Clauses 3, 5, 6, 10, and 11 of the Regulations for the Membership, Certificates of having passed the preliminary examination; of having performed Dissections during three winter sessions; of having attended one course of lectures on Comparative Anatomy and one course of Lectures on Chemistry.

II. Except in the cases provided for to the contrary, every candidate before his admission to the Second or Professional Examination is required to produce, in addition to the certificates described in Section II, Clauses 7, 8, 9 (except Chemistry, included in the first examination), 12, 14, and 15 of the Regulations for the Diploma of Member, certificates of being 25 years of age; of having been engaged for six years in the acquirement of professional knowledge in hospitals or schools of Anatomy, Surgery, and Medicine recognised by the Council of the College (or, if the candidate be already a Member of the College, certificates of having been engaged for two years in the acquirement of professional knowledge in recognised hospitals and schools, in addition to the certificates required for the diploma of Member); of having performed Operations on the dead body under the superintendence of a recognised teacher; of having attended the Surgical Practice of a recognised hospital or hospitals during four winter and four summer sessions, and the Medical Practice during one winter and one summer session; of having attended, during three winter and two summer sessions, demonstrations in the *post mortem* rooms of a recognised hospital; of having attended Clinical Lectures on Medicine during one winter and one summer session; and of having served the office of house-surgeon or dresser for not less than six months.

III. In the case of a candidate who shall have taken by examination the Degree of Bachelor or Master of Arts in any University in the United Kingdom recognised by the Council, it shall be sufficient for him to produce a certificate or certificates that he has been engaged for five years (instead of six years) in the acquirement of professional knowledge in hospitals or schools of Anatomy, Surgery, and Medicine recognised by the Council of the College.

IV. Any Member of the College shall, after the expiration of eight years from the date of his diploma, be entitled to be admitted to the professional examination for the Fellowship upon the production of a certificate, signed by three Fellows, that he has been for eight years in

the practice of the profession of surgery, and that he is a fit and proper person to be admitted a Fellow if upon examination he shall be found qualified.

##### Section III.—Professional Examinations.

The examinations are held twice in the year, in May and November, and at such other times as the Council may appoint. They occupy not less than two days. The subjects of the first examination are the same as for the membership; the second examination, on Pathology, Therapeutics, and the Principles and Practice of Surgery and Medicine,\* is partly written, partly *vivâ voce*, and partly on the practical use of surgical apparatus, and includes the examination of patients, and operations on the dead body.—The Fees are: for the first examination Five Guineas, to be allowed on the fee for the Diploma of Fellow, but to be retained in case of rejection; for the second examination Five Guineas (if the candidate be a member) over and above charges for stamps, to be retained in case of rejection; Twenty-five Guineas (if he be not a Member) over and above charges for stamps, of which Five Guineas will be retained in case of rejection.† A candidate whose qualifications are found insufficient on his anatomical and physiological examination cannot present himself for re-examination until after the expiration of six months; and a candidate whose qualifications shall be found insufficient upon his pathological and surgical examination cannot present himself for re-examination until after the expiration of one year, unless the Court of Examiners shall otherwise determine.

#### SOCIETY OF APOTHECARIES, LONDON.

##### REGULATIONS RELATING TO ALL CANDIDATES FOR EXAMINATION.

Every candidate for a certificate of qualification to practise as an Apothecary will be required to produce testimonials—1. Of having passed a preliminary examination in Arts, as a test of general education. (This examination must be passed before the commencement of professional studies, which is defined by the Medical Council to be "the time of commencing studies at a medical school".) 2. Of having served an apprenticeship or pupilage of not less than five years to a practitioner qualified by the Act of 1815. (This period may include the time spent in attending lectures and hospital practice.) 3. Of having attained the full age of 21 years. 4. Of good moral conduct. 5. Of having pursued a course of medical study in conformity with the regulations of the Court. 6. Of having served the office of clinical clerk at a recognised hospital during the period of six weeks at least. 7. Of having been examined at the class-examinations instituted by the various lecturers and professors of the respective medical schools and colleges.

The Court meets every Thursday; and candidates are required to attend at 3.45 P.M. Every candidate intending to offer himself for examination must give notice on or before the Monday previous to the day of examination, and must at the same time deposit all the required testimonials, with the fee, at the office of the beadle, where attendance is given every day, except Sunday, from ten to four o'clock; Saturdays, ten to two.

##### Course of Study.

Every candidate whose attendance on lectures shall have commenced on or after October 1, 1863, must attend the following lectures and medical practice during not less than three winter and two summer sessions (each winter session to consist of not less than six months, and to commence not sooner than the 1st nor later than the 15th of October; and each summer session to extend from May 1 to July 31). *First Year: Winter Session:* Chemistry; Anatomy and Physiology; Dissections. *Summer Session:* Botany; Materia Medica and Therapeutics; Practical Chemistry.—*Second Year: Winter Session:* Anatomy and Physiology, including Dissections and Demonstrations; Principles and Practice of Medicine; Clinical Medical Practice. *Summer Session:* Midwifery and Diseases of Women and Children, and Vaccination; Forensic Medicine and Toxicology; Clinical Medical Practice.—*Third Year: Winter Session:* Principles and Practice of Medicine; Clinical Medical Lectures; Morbid Anatomy; Clinical Medical Practice.—No certificates of lectures or of anatomical instruction delivered in private to particular students, apart from the ordinary classes of recognised public medical schools, can be received by the Court of Examiners.—All students are required *personally* to register the several tickets of

\* The sum of twenty-two pounds is exclusive of the fee of two pounds paid for the preliminary examination.

† See Regulations for the Diploma of Member, Section I, Clause 1.

‡ For the Subjects, see Note to Section I, Clause 9, page 286.

\* For the condition of exemption from examination in Medicine, see Regulations respecting the Diploma of Member, Section IV, Clause 2. A candidate who has passed an examination in Medicine for the Membership will not be required to pass any further examination in Medicine for the Fellowship.

† The sum of £2, paid on the Preliminary Examination, will be allowed against these amounts.

admission to lectures and medical practice within the first fifteen days of the months of October and May.

Examinations in the subjects of preliminary education will be held at the Hall of the Society on Friday and Saturday, January 26th and 27th, April 26th and 27th, September 27th and 28th, 1872.—Candidates will be examined in the following branches; and no candidate will be approved unless he show a competent knowledge of each branch:—1. The English Language; 2. The Latin Language; 3. Mathematics; 4. One of the following subjects, at the option of the candidate; (a) Greek; (b) French; (c) German; (d) Natural Philosophy.\* Candidates applying to be admitted to any examination must pay the fee (One Guinea) at least one week before the examination; and must sign their names in the candidates' book between 11 A.M. and 3 P.M., not later than the previous Thursday.

If a candidate fail to pass the examination, the fee will not be returned to him; but he will be admissible to either or both of the two next following examinations in Arts without the payment of an additional fee, upon giving the usual notice, and signing the candidates' book. Certificates in Arts granted by any of the bodies whose certificate is recognised by the Medical Council will be accepted as equivalent to having passed the above examination.

The examination of candidates for the Licence is divided into two parts, and is conducted partly in writing, and partly *vivâ voce*.

The *First Examination*, which may be passed after the second winter session, embraces the following subjects:—The *British Pharmacopœia*; Latin of Physicians' Prescriptions; Anatomy and Physiology; General and Practical Chemistry; Botany and *Materia Medica*.

The *Second Examination*, after the third winter session (the five years' pupillage having been completed), includes: Principles and Practice of Medicine; Pathology and Therapeutics; Midwifery, including the Diseases of Women and Children; Forensic Medicine and Toxicology.

*Modified Examinations.*—All Graduates in Medicine of British Universities will be admitted to a practical examination in Medicine and Midwifery only.—Licentiates of the Royal Colleges of Physicians of London or of Edinburgh; of the Royal Colleges of Physicians and Surgeons, Edinburgh; of the King and Queen's College of Physicians, Ireland; of the Faculty of Physicians and Surgeons, Glasgow; and of the Apothecaries' Hall, Dublin, will be admitted to a *vivâ voce* examination in Medicine, Midwifery, Forensic Medicine, and Toxicology.—Members of the Royal College of Surgeons of England; and Licentiates of the Royal Colleges of Surgeons of Edinburgh, and of Ireland, possessing a surgical qualification only, will be admitted to a first and second examination on one evening. The first, or *vivâ voce* examination, will include Physicians' Prescriptions, Visceral Anatomy, Physiology, Chemistry, *Materia Medica*, Botany, and Pharmacy; the second, partly written and partly *vivâ voce*, will include Practice of Medicine, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Toxicological Chemistry.—Any candidate who has passed his first examination for the Licence of the Royal College of Physicians, London; the Licence of the King and Queen's College of Physicians, Ireland; the joint Licence of the Royal Colleges of Physicians and Surgeons, Edinburgh; or for the single Licence of the College of Physicians, Edinburgh; the Licence of the Faculty of Physicians and Surgeons, Glasgow; the first professional examination for the Degree of M.B., or Master in Surgery in the Universities of Oxford, Cambridge, or London; or the second part of the professional examination for the degree of M.D., or Master in Surgery in the Universities of Edinburgh, Aberdeen, St. Andrew's, and Glasgow; or the first examination for medical and surgical degrees in the Irish Universities; or the first examination for the Licence of the Apothecaries' Company, Dublin, will be admitted to a single examination in *Materia Medica*, Therapeutics, Medicine, Pathology, Midwifery, and Toxicology, part of which examination will be conducted in writing.

No rejected candidate for the Licence can be re-examined until the

\* The following is the Syllabus of Subjects for Examination in 1872. 1. English. The leading features of its History. Its Structure and Grammar. English Composition. [The Books recommended for study in this subject are Adams's *Elements of the English Language*, and Trench, *English, Past and Present*.]—2. Latin. January: Virgil, *Æneid*, Books I and II. April: Cicero, *Oratio pro Milone*. September: Horace, *Odes*, Books III and IV. Re-translation of easy sentences. Grammatical Questions will be introduced into the Latin Paper, and each Candidate will be expected to give satisfactory answers to these.—3. Mathematics: The Ordinary Rules of Arithmetic; Vulgar and Decimal Fractions; Addition, Subtraction, Multiplication, and Division of Algebraical Quantities; Simple Equations; The First Two Books of Euclid.—4. (a) Greek: Herodotus, Book I; Grammatical Questions. (b) French: Molière, *Le Bourgeois Gentilhomme*; Translation from English into French; Grammatical Questions. (c) German: Schiller, *Der Taucher*, and *Der Gang nach dem Eisenhammer*; Translation of short sentences from English into German; Grammatical Questions. (d) Natural Philosophy: Mechanics; Hydrostatics and Pneumatics. [The Book recommended for study in this subject is Snowball's *Cambridge Course of Elementary Natural Philosophy*.]

expiration of six months from his former examination. A candidate rejected on his first professional examination can be admitted to re-examination after the expiration of three months.

*Fees.*—For a certificate of qualification to practise, Six Guineas, the half to be paid at the first examination; for an assistant's certificate, Two Guineas.

*Prizes.*—The Society of Apothecaries annually offer two prizes for proficiency in the knowledge of Botany, and also two prizes for proficiency in the knowledge of *Materia Medica* and Pharmaceutical Chemistry. The prizes consist of a gold medal awarded to the candidate who distinguishes himself the most in the examination; and of a silver medal and a book to the candidate who does so in the next degree. The examination in Botany will be held at the Hall of the Society on the second Wednesday in June, at 10 A.M., and will be conducted by printed papers and *vivâ voce* question. The examinations in *Materia Medica* and Pharmaceutical Chemistry will be held at the Hall of the Society on the third Wednesday, and on the following Friday, in October, from ten in the forenoon to one in the afternoon of each day; by printed papers on the Wednesday, and by *vivâ voce* questions on the Friday.

## UNIVERSITY OF OXFORD.

### DEGREES IN MEDICINE.

EVERY student must reside either in one of the Colleges or Halls, or in a Licensed Lodging-House for three years. During these three years he has to pass two examinations in Arts, and one in either Mathematics, Natural Science, or Law and Modern History; when, if he obtain a first, second, or third class, he can take his B.A. degree; if he do not gain such honours, he has to pass a third examination in *Literis Humanioribus*. A student deciding to graduate in medicine must, after passing the requisite examination for the degree of B.A., spend two years in study prior to a scientific examination for the Degree of Bachelor of Medicine, unless he shall have taken a first or second class in the natural science school, when he may go in at the first opportunity for the first M.B. Examination. Two years after passing this examination, and after four years of professional and scientific study, he may go in for the second or practical examination for the M.B. Degree. These four years of medical study may be spent either in or out of Oxford, in an approved medical school.

The M.B. Degree confers the License to practise. For the Degree of Doctor in Medicine a dissertation has to be publicly read three years after taking the M.B. Degree.

The medical examinations take place annually in Michaelmas Term.

Scholarships of about the value of £75 are obtainable at Christ Church, Magdalen, and other Colleges, by competitive examination in natural science. Every year a Radcliffe Travelling Fellowship is competed for by any one who, having taken a first-class in any of the Public Examinations of the University, or having obtained some University Prize or Scholarship open to general competition, proposes to study medicine. The travelling Fellows receive £200 a year for three years, half this period being spent in study abroad.

## UNIVERSITY OF CAMBRIDGE.

### DEGREES IN MEDICINE AND SURGERY.

#### *Degree of Bachelor of Medicine.*

A STUDENT proceeding to this degree must—1, Reside in the University two-thirds of each of nine terms; 2, Pass the previous examination; 3, Pursue medical study for five years, unless he have obtained honours in the Mathematical, Classical, Moral Sciences, or Natural Sciences Tripos, in which case only four years are required. Of this time of five years he must spend six terms in medical study in the University† after

\* A student who is, at least, in his second term of residence, may be admitted to the previous examination, and also to the examination in the additional subjects, held in the Lent Term, provided he presents to the Registry a certificate from the Master of his College, or his *locum tenens*, stating that he has declared that it is *bonâ fide* his intention to register himself as a medical student and to study medicine in the University. But in order that such a student may be admitted to the examination for any Tripos, or to the Degree of Bachelor of Arts or Bachelor of Law, a certificate from the Regius Professor of Physic that he has been *bonâ fide* engaged in medical study, including hospital practice, subsequently to having passed the previous examination, and also certificates that he has attended three courses of medical lectures subsequently to his having passed the previous examination, must be presented to the Council.

† That is, by attending, in each Term, courses of lectures delivered in the University on two of the following subjects; viz., Chemistry, Botany, Human Anatomy and Physiology, Comparative Anatomy, *Materia Medica* and Pharmacy, Pathology; or, instead of two courses of lectures, by attending one course of lectures and the Medical Practice of Addenbrooke's Hospital.

passing the previous examination, unless he has obtained honours in one of the above-mentioned Triposes, in which case four terms only are required.—A student who has not graduated in Arts is required, before keeping the terms of medical study, in addition to passing the previous examination, to pass in Algebra either in the examination for the additional subjects of the previous examination (which he may do in his second term of residence or in any subsequent term), or in the general examination for the ordinary B.A. Degree.

There are three examinations for the Degree of Bachelor of Medicine, conducted partly by written answers, and partly *visû voce*. The examinations include chemical analysis, the recognition and description of specimens (healthy, morbid, and microscopical), dissections, and the examination of patients.

The subjects of the first examination are—1, Mechanics and Hydrostatics; 2, Chemistry with Heat and Electricity; 3, Botany.\* The student may present himself for this examination at any time after passing the previous examination. He must produce certificates of having diligently attended one course of lectures on Chemistry, including manipulations, and one course on Botany.

The subjects of the second examination are—1, Elements of Comparative Anatomy;† 2, Human Anatomy and Physiology; 3, Pharmacology. Before presenting himself for this examination, the student must have completed two years of medical study, the time of medical study required to be spent in the University being included in these two years. He must have attended hospital practice during one year, have practised dissection during one season, and must produce certificates of having diligently attended a course of lectures on each of the following subjects:—1, Elements of Comparative Anatomy; 2, Human Anatomy and Physiology; 3, Materia Medica and Pharmacy; 4, Pathology.

The subjects of the third examination are—1, Pathology and the Practice of Physic (two papers); 2, Clinical Medicine; 3, Medical Jurisprudence.—Before presenting himself for this examination, the student must have completed the course of medical study, must have attended hospital practice during three years, and must produce certificates of having attended one course of lectures on each of the following subjects:—1, Principles and Practice of Physic; 2, Clinical Medicine; 3, Clinical Surgery; 4, Medical Jurisprudence; 5, Midwifery.

After these examinations have been passed, an Act must be kept in the schools. The candidate reads a thesis, composed in English by himself on some subject approved by the professor; the professor brings forward arguments or objections in English for the candidate to answer, and examines him *visû voce* as well as on questions connected with his thesis as on other subjects in the faculty of a more general nature. The exercise must continue at least one hour.

#### Degree of Doctor of Medicine.

This may be taken by a Bachelor of Medicine in the ninth term after his inauguration. He is required to produce certificates of having been engaged five years in medical study, to keep an act similar to that for M.B., and write an extempore essay. He pays ten guineas to the Professor of Physic for the act.—A Master of Arts may proceed to the Degree of M.D. in the twelfth term after his inauguration as M.A. without having taken the Degree of M.B. He must pass the three examinations for M.B., and keep the act, for the M.D. Degree. He must produce certificates of having been engaged five years in medical study, and the same certificates of attendance on lectures and hospital practice are required as of the candidate for the Degree of M.B.; but he is not required to have kept medical terms in the University.

#### Degree of Master of Surgery.

The subjects of the examination for this degree are—1, Surgical Anatomy; 2, Pathology and the Principles and Practice of Surgery; 3, Clinical Surgery; 4, Midwifery. Before admission to this examination, the candidate must have passed all the examinations for the Degree of M.B., and must produce certificates of having attended the surgical practice of a hospital for three years, of having been house surgeon or dresser for six months, and of having attended—1, a second course of lectures on Human Anatomy; 2, one course of lectures on the Principles and Practice of Surgery; 3, lectures on Clinical Surgery, during one year; 4, the course of Midwifery; 5, of having practised Dissection

during a second season.—The examination takes place at the same time as those for M.B., and in a similar manner. The candidate is required to perform operations on the dead body, and to examine patients in the hospital.

### UNIVERSITY OF LONDON.

#### DEGREES IN MEDICINE AND SURGERY.

THE following Examinations for Degrees in Medicine are held in the University of London. Each takes place once yearly.

*Preliminary Scientific Examination*, commencing on the third Monday in July.

*Bachelor of Medicine (M.B.) First Examination*: Last Monday in July.

*Bachelor of Medicine (M.B.) Second Examination*: First Monday in November.

*Bachelor of Surgery (B.S.)*: Tuesday following the fourth Monday in November.

*Master in Surgery (M.S.)*: Fourth Monday in November.

*Doctor of Medicine (M.D.)*: Fourth Monday in November.

The certificates in each case must be transmitted to the Registrar at least fourteen days before the commencement of the examination.

The fee for each examination is Five Pounds.\* If a candidate withdraw or fail to pass either of the examinations, the fee is not returned; but he is admitted without further payment to two subsequent preliminary scientific, first M.B., second M.B., or B.S. examinations, or to one subsequent M.S. or M.D. examination, provided that he give notice to the Registrar at least fourteen days before the commencement of the examination.

#### Bachelor of Medicine.

Every candidate for the Degree of Bachelor of Medicine is required—1. To have passed the Matriculation Examination, or to have taken a Degree in Arts in either of the Universities of Sydney, Melbourne, or Calcutta (provided in the last case, that Latin has been one of the subjects in which he has passed). 2. To have passed the preliminary Scientific Examination.† 3. To have been engaged in his professional studies during four years subsequently to Matriculation or Graduation in Arts, or one or more of the medical institutions or schools recognised by this University; one year, at least, of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in medicine.

*First M.B. Examination*.—The candidate must produce certificates:—1. Of having completed his nineteenth year. 2. Of having passed the preliminary scientific examination at least one year previously. 3. Of having been a student during two years at one or more of the medical institutions or schools recognised by this University; and of having attended a course of lectures on each of three of the following subjects: Descriptive and Surgical Anatomy; General Anatomy and Physiology; Comparative Anatomy; Pathological Anatomy; Materia Medica and Pharmacy; General Pathology; General Therapeutics; Forensic Medicine; Hygiene; Obstetric Medicine and Diseases peculiar to Women and Infants; Surgery; Medicine.‡ 4. Of having dissected during two winter sessions. 5. Of having attended a course of Practical Chemistry. 6. Of having attended to Practical Pharmacy, and of having acquired a practical knowledge of the preparation of medicines. Candidates are examined in Anatomy; Physiology;§ Materia Medica

\* For the degree of Doctor of Medicine, the fee will continue to be Ten Pounds to all such as, having taken their M.B. degree under the former regulations, shall not have paid the fee of Five Pounds at the Preliminary Scientific Examination.

† Candidates for the Degree of M.B. are strongly recommended by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies. For the Preliminary Scientific Examination, a candidate must have completed his seventeenth year, and have either passed the Matriculation Examination or taken a degree in Arts in either of the Universities of Sydney, Melbourne, or Calcutta (provided in the last case that Latin be one of the subjects in which he has passed). Candidates are examined in Mechanical Philosophy, including Statics, Dynamics, Hydrostatics, Hydraulics, Pneumatics, and Optics; Natural Philosophy, including Heat, Electricity, and Magnetism; Inorganic Chemistry; Botany and Vegetable Physiology; Zoology. They must show a competent knowledge in all the subjects of examination. Candidates who matriculated previously to January 1867 are not required to pass the Preliminary Scientific Examination in any other subjects than Chemistry and Botany; and they are allowed to pass the Preliminary Scientific Examination and the First M.B. Examination in the same year, if they so prefer.

‡ The subjects numbered 2, 4, and 5, must be attended after taking a Degree in Arts or passing the Matriculation Examination.

§ Any candidate is allowed, if he so prefer, to postpone his examination in Physiology from the First M.B. Examination at which he presents himself for examination in the remaining subjects until the First M.B. Examination in the next or any subsequent year; but such candidate is not admitted to compete for honours on either occasion, and he cannot be admitted as a candidate at the Second M.B. Examination until after the lapse of at least twelve months after having passed his examination in Physiology.

and Pharmaceutical Chemistry; Organic Chemistry. Candidates must show a competent knowledge in all the subjects of examination. The examinations are conducted by printed papers and *vivâ voce* interrogation, by demonstration from preparations and specimens, and by dissections. After 1871, there will be a practical examination in histology.

*Examination for Honours.*—Any candidate who has been placed in the first division may be examined for Honours in (1) Anatomy, (2) Physiology, Histology, and Comparative Anatomy, and (3) Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry. If in the opinion of the examiners sufficient merit be evinced, the candidate who distinguishes himself most in each of these three divisions receives an exhibition of £40 *per annum* for the next two years, payable in quarterly instalments; provided that on receiving each instalment he declare his intention of presenting himself at the second M.B. examination within three years from the time of passing the first M.B. examination. Under the same circumstances, the first and second candidates in each subject receive each a Gold Medal of the value of Five Pounds.

*Second M.B. Examination.\**—No candidate is admitted to this examination within two academical years of the time of his passing the first examination, nor without certificates:—1. Of having passed the first M.B. examination. 2. Of having subsequently attended a course of lectures on each of two of the subjects for which he had not presented certificates at the first examination. 3. Of having conducted at least twenty labours.† 4 and 5. Of having attended the surgical and the medical practice of a recognised Hospital or Hospitals during two years, with Clinical Instruction and Lectures on Clinical Surgery and Clinical Medicine.‡ 6. Of having, subsequently to the completion of his attendance on surgical and medical hospital practice, attended to Practical Medicine, Surgery, and Midwifery, with special charge of patients, in Hospital, Infirmary, Dispensary, or Parochial Union, during six months. 7. Of having acquired proficiency in vaccination.§ The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. Candidates are examined in General Pathology, General Therapeutics, and Hygiene; Surgery; Medicine; Midwifery; Forensic Medicine. The examinations include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry. The examinations are conducted by printed papers and *vivâ voce* interrogation; by practical examinations on obstetric preparations and apparatus; by examination, and report on cases, of medical patients in the wards of a hospital; demonstration from specimens and preparation. Candidates are expected to write prescriptions in Latin, without abbreviations.

Bachelors of Medicine of the University of London have no right, as such, to assume the title of Doctor of Medicine.

*Examination for Honours.*—Any candidate who has been placed in the first division may be examined for Honours in (1) Medicine, (2) Midwifery, and (3) Forensic Medicine. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most in Medicine receives £50 *per annum* for the next two years, with the style of University Scholar in Medicine; and the candidates who distinguish themselves the most in Midwifery and in Forensic Medicine receive each £30 *per annum* for the next two years, with the style of University Scholar in Obstetric Medicine and in Forensic Medicine respectively. The first and second candidates in each of the preceding subjects each receive a Gold Medal of the value of Five Pounds.

#### *Bachelor of Surgery.*

The candidate must produce certificates:—1. Of having taken the Degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having

\* Any candidate for the Second M.B. Examination who has passed the First M.B. Examination under the former regulations, is required to have also passed the Examination in Physiology at some previous First M.B. Examination carried on under the present regulations; at which examination he is not allowed to compete for honours.

† Certificates on this subject will be received from any legally qualified practitioner in medicine.

‡ The student's attendance on the Surgical and on the medical hospital practice specified in Regulations 4 and 5, may commence at any date after his passing the Preliminary Scientific Examination, and may be comprised either within the same or within different years; provided that in every case his attendance on Hospital Practice be continued for at least eighteen months subsequently to his passing the First M.B. Examination. Attendance during three months in the wards of a Lunatic Asylum recognised by the University, with clinical instruction, may be substituted for a like period of attendance on medical hospital practice. The Senate regard it as highly desirable that candidates for the Degree of M.B. should practically acquaint themselves with the different forms of insanity by attendance in a Lunatic Asylum.

§ Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council.

operated on the dead subject. The examinations are conducted by printed papers on surgical anatomy and surgical operations; by examination and report on cases of surgical patients; by performance of operations upon the dead subject; by application of surgical apparatus; and by *vivâ voce* interrogation.

*Examination for Honours.*—Any candidate who has passed the B.S. examination may be examined for Honours in Surgery. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most receives £50 *per annum* for the next two years, with the style of University Scholar in Surgery; and the first and second candidates each receive a Gold Medal of the value of Five Pounds.

#### *Master in Surgery.*

The candidate must produce certificates:—1. Of having taken the Degree of Bachelor of Surgery\* in this University. 2. Of having attended subsequently—(a) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; (b) or to Clinical or Practical Surgery during one year in a recognised hospital or medical institution, and of having been engaged during three years in the practice of his profession; (c) or of having been engaged during five years in the practice of his profession, either before or after taking the Degree of Bachelor of Surgery in this University.† 3. Of moral character, signed by two persons of respectability. The examination is conducted by means of printed papers and *vivâ voce* interrogation; and the candidates are examined in Logic and Moral Philosophy,‡ and in Surgery. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most at this examination receives a Gold Medal of the value of Twenty Pounds.

#### *Doctor of Medicine.*

The candidate must produce certificates analogous to those required for candidates for the Degree of Master in Surgery, but having special relation to Medicine. The examination is conducted by printed papers and *vivâ voce* interrogation; and candidates are examined in Logic and Moral Philosophy, and in Medicine. If, in the opinion of the examiners, sufficient merit be evinced, the candidate who distinguishes himself the most at this examination receives a Gold Medal of the value of Twenty Pounds.

### UNIVERSITY OF DURHAM.

#### REGULATIONS REGARDING DEGREES IN MEDICINE.

EVERY student in medicine must have been registered, and no one shall be registered unless he have passed the Registration Examination or such other examination as the Warden and Senate shall deem equivalent. The Registration Examination is directed to the rudiments of Religion, Literature, and Science; and is conducted by two or more examiners nominated by the Warden. The Registration Examination will begin on April 18th and September 19th, 1871, at 9 A.M. on each day.

#### *Licence in Medicine.*

The candidate must be of the age of 21 years, and must, since his registration, have spent four years in medical study at one or more of the schools recognised by the Licensing Bodies named in Schedule A of the Medical Act, 1858. There are two public examinations: the first after two years at least of medical study; the second after four years at least of medical study. Candidates must produce satisfactory testimonials of conduct, and such certificates of attendance on lectures and hospital practice as the Warden and Senate shall require.

#### *Bachelor of Medicine.*

The candidate must be of the standing of three terms at least as a Licentiate in Medicine, and of eighteen terms (six years) at least from the date of registration or matriculation.—No one who is not a Bachelor of Arts shall be admissible to the Degree of Bachelor of Medicine, unless he have kept three terms by residence at Durham or

\* Candidates who have obtained the degree of Bachelor of Medicine previously to 1866, will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates, the attendance on surgical practice required by regulation 2, may commence from the date of the M.B. Degree.

† One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division.

‡ Any candidate who has taken the degree either of B.A., B.Sc., or M.D. in this University, is exempted from this part of the examination; and any candidate who has passed the Second M.B. Examination, may at any subsequent M.S. Examination present himself for Logic and Moral Philosophy alone, if he so prefer; thereby gaining exemption, if he should pass, from examination in that subject when he presents himself to be examined for the degree of Master in Surgery.—An analogous exemption is allowed in the case of candidates for the degree of M.D.

at Newcastle, and have passed the final examination for the Degree of Bachelor of Arts, or an equivalent to it, besides the examination for the Degree of Bachelor of Medicine, nor unless he have spent one year at least in medical study at some school of medicine in connexion with the University.—The examination for the Degree of Bachelor of Medicine is directed chiefly to the Practice of Medicine.

#### *Doctor of Medicine.*

The candidate must be a Bachelor of Medicine of the standing of twenty-one terms at least (seven years) from his registration or matriculation, and of three terms at least from his admission to the Degree of Bachelor of Medicine; and must perform such exercises as the Warden and Senate require.

#### *Licence in Surgery.*

The candidate must be of the age of 21 years, and have spent four years in medical and surgical study since his registration as a student in medicine. In other respects, the regulations are similar to those for the Licence in Medicine; but the second examination is partly in surgical subjects.—The second examination for a Licence in Surgery may or may not be passed at the same time with the second examination for a Licence in Medicine.

#### *Master in Surgery.*

The candidate must be a Licentiate in Surgery, and also a Licentiate in Medicine, and of the standing of eighteen terms (six years) at least from the date of his registration or matriculation, and of three terms at least from the date of his admission to the Licence in Surgery.—[In other respects, the regulations for this degree are analogous to those for that of Bachelor of Medicine, but having relation to Surgery in place of Medicine.]

The Warden and Senate shall have authority to arrange for students in the Faculty of Medicine an examination equivalent to that for the Degree of Bachelor of Arts, by substituting for the theological part of it an examination in Hippocrates, Galen, or such other ancient medical author or authors as they may think fit.

Any student in medicine who was registered before Easter Term, 1868, shall be entitled to be admitted to the Degree of Master in Surgery on the same conditions as above are required for a Licence in Surgery.

These regulations shall not interfere with the power of the University to grant degrees by diploma to persons of sufficient standing and approved merit.

*Fees for Examination and Degrees.*—Senior Middle-Class Examination, £1; Examination at the end of First Year, £1; Registration Examination, £1; Extraordinary Registration Examination, £2; Registration, 5s.; each Public Examination in Medicine and in Surgery, £1; Licence in Medicine or Surgery, £3; Degree of Master in Surgery, Bachelor in Medicine, or Doctor in Medicine, each £6.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

#### REGULATIONS FOR THE LICENCE.

No one can obtain the Licence of the College until he has completed the age of 21 years. Every applicant must produce satisfactory evidence of having been engaged in the study of medicine during at least four years subsequently to registration as a medical student, and of having attended the following courses at a University, or at a medical school recognised by the College:—Anatomy, Practical Anatomy, Chemistry, Practice of Medicine, Clinical Medicine, and Principles and Practice of Surgery, each a six months' course; Practical Chemistry, Materia Medica and Pharmacy, Physiology or Institutes of Medicine, Clinical Surgery, Midwifery, Medical Jurisprudence, General Pathology or Pathological Anatomy, and Practical Pharmacy, each a three months' course. The applicant must have attended the practice of a Public Hospital (containing not fewer than eighty beds) during not less than twenty-four months, twelve of which must have been spent in attendance on the medical wards. He must also have attended for six months the practice of a public dispensary, or have acted for six months as clinical clerk or dresser in a hospital; or have been engaged during six months as a visiting assistant to a registered practitioner. He must also have attended at least six cases of labour under the superintendence of a qualified medical practitioner. Every applicant, before being admitted to the final examination, will be required to produce a certificate that he has studied vaccination under a competent and recognised teacher, and that he is thoroughly informed in every necessary part of the subject. He must have passed the Preliminary Examination in Literature and Science before he can be admitted to the professional examination.\* Masters and Bachelors of Arts of any British or

Foreign University, whose course of study may from time to time be approved of by the College, will be exempted from the preliminary examination; also those who have passed the examination of the national educational bodies, or of any of the licensing boards recognised by the Medical Act.

The professional examination will be divided into two parts: (1) Anatomy, Physiology, Chemistry; (2) Materia Medica and Pharmacy, Pathology and Pathological Anatomy, Practice of Medicine, Midwifery, Medical Jurisprudence, Clinical Medicine. No candidate will be admitted to the first examination until he has completed two, or to the second until he has completed four, years of professional study. The following will be the periods of examination to October 1872:—1. Preliminary examinations, October 21 and November 4, 1871; April 20 and July 20, 1872. 2. First professional examinations, October 18, 1871; January 17, March 27, May 1, July 17, and October 16, 1872. The second professional examinations will be held on the Thursdays following the first professional.

Candidates who already possess a qualification from a recognised Licensing Body, or who have passed the first professional examination before a qualifying body (provided it be as extensive as that required by this College), will be at once admitted to the second examination. Meetings for the examination of candidates who already possess a qualification from a recognised Licensing Body will be held on the first Wednesday of every month (except September and October), and, if necessary, on the following days. Candidates are required to communicate with the Secretary to the College not less than eight days before the date of the examination.

No candidate is admissible to examination who has been rejected by any other licensing board within three months previous to his examination.

The Fee payable by a Licentiate is Ten Guineas. If a candidate be unsuccessful, Two Guineas will be retained to pay expenses.

Candidates may be admitted to special examination on bringing forward satisfactory reasons and paying an extra Fee.

### ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

#### REGULATIONS FOR CANDIDATES FOR THE DIPLOMA.

The regulations regarding schools of medicine, preliminary examination, and professional study and examination, are similar to those for the double qualification (see next page), except that the third course of Medicine and the course of Pathological Anatomy are not required.

Registered medical practitioners whose degree or licence in medicine is dated prior to October 1st, 1861, are exempt from the first professional examination. The examinations under this regulation may take place on the first and third Tuesdays of each month.

At the second examination, the student, in furnishing the statement of his professional study, must, if he has been an apprentice, insert the name of his master, the date of his indenture, and the length of time for which he was bound. If the candidate have been an apprentice to a Fellow of the College, he must also produce his discharged indenture.

Recent Dissections, Anatomical Specimens, and articles of the Materia Medica, are employed during the examinations; and all candidates are required to write out formulæ of prescription. They are also subjected to a practical clinical examination in the Surgical Hospital.

No candidate shall be admissible to examination who has been rejected by any other Licensing Board within three months preceding his application to be examined.

The Fees are: for the first examination, £4; for the second, £6; in each £2 will be returned to unsuccessful candidates. The Fee from candidates who have elsewhere passed the first professional examination is £10, of which £2 is retained if the candidate be unsuccessful.

Special examinations are held when required, the regulations being the same as in Clause 16 of the regulations for the professional examination for the double qualification, and an extra Fee being paid.

### ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.

#### DOUBLE QUALIFICATION IN MEDICINE AND IN SURGERY.

THE Royal College of Physicians of Edinburgh and the Royal College of Surgeons of Edinburgh, while they still continue to give their Diplomas separately, have made arrangements by which, after one series of examinations, the student may obtain the Diplomas of both Colleges. This joint examination is conducted by a Board, in which each body is represented for examination in those branches which are common to both Medicine and Surgery; but the College of Physicians takes exclu-

\* In the subjects, see note to regulations for double qualification.

sive charge of the examination in Medicine, and the College of Surgeons of the examination in Surgery. Students passing that examination are enabled to register two qualifications—Licentiate of the Royal College of Physicians of Edinburgh, and Licentiate of the Royal College of Surgeons of Edinburgh.

1. Every candidate must have followed his course of study in an University, or in an established School of Medicine, or in a Provincial School specially recognised by the College of Physicians and Surgeons of that division of the United Kingdom in which it is situate. 2. Under the title *Established School of Medicine* are comprehended the medical schools of those cities of Great Britain and Ireland in which Diplomas in Medicine or Surgery are granted, and such Colonial and Foreign Schools as are similarly circumstanced in the countries in which they exist.

#### Professional Education.

1. Candidates commencing professional study after September 16th, 1866, must have been engaged, during four years after the examination in general education, in not less than four winter sessions' or three winter and two summer sessions' attendance at a recognised medical school.\* 2. The candidate must have attended the following courses of lectures:—Anatomy, two courses† of six months each, and Practical Anatomy, twelve months; or Anatomy, one course of six months, and Practical Anatomy, eighteen months; Physiology, not less than fifty lectures;‡ Chemistry, Practice of Medicine, Clinical Medicine, § Medicine (a third course, either Practice or Clinical, at option), § Principles and Practice of Surgery, Clinical Surgery, § Surgery (a third course, either Principles and Practice or Clinical Surgery, at option), § each six months; Practical or Analytical Chemistry, Materia Medica, Midwifery, and Diseases of Women and Children, Medical Jurisprudence, and Pathological Anatomy, || each three months.¶ 3. He must also produce certificates:—*a.* Of having attended at least six cases of labour under the superintendence of a registered medical practitioner. *b.* Of having attended, for three months, instruction in Practical Pharmacy. The teacher signing the certificate must be a Member of the Pharmaceutical Society of Great Britain, or a chemist and druggist recognised by either College on special application, or the superintendent of the laboratory of a Public Hospital or Dispensary, or a registered practitioner who dispenses medicine to his own patients. *c.* Of having attended, for twenty-four months, a public General Hospital containing, on an average, at least eighty patients. *d.* Of having attended, for six months, the practice of a public Dispensary specially recognised by either College; or of having been engaged for six months as assistant to a registered practitioner. *e.* Of having been instructed in vaccination; the certificate to be signed by the teacher, who must be a registered practitioner.—It is strongly recommended to students to avail themselves of opportunities of attending lectures on Ophthalmic and Mental Diseases, also on Natural History and Comparative Anatomy; and of obtaining practical instruction in the use of the Microscope.\*\*

#### Preliminary Examination in General Education.

All students who intend becoming candidates for the Diplomas of the Colleges must have passed the complete examination in General Education,†† and have had their names inscribed in the Register of Me-

\* Candidates commencing study prior to the above date, will be admitted to examination after four winter sessions' or three winter and two summer sessions' attendance on classes at a regular Medical School.

† The two courses must not be attended in the same session.

‡ In those Schools of England and Ireland in which two separate courses of Lectures are delivered at separate hours—one on Anatomy, the other on Anatomy and Physiology—the former of these courses will be received as a course of Anatomy, and the other as a course of Physiology.

§ Two courses of Clinical Medicine or of Clinical Surgery of three months each, if not simultaneous, will be held equivalent to one course of six months. They must be attended during the period of attendance at the Hospital where they are delivered.

|| A certificate of attendance at the *Post Mortem* Examinations at a General Hospital will be accepted in lieu of this course.

¶ The six months' courses delivered in Scotland must consist of not fewer than one hundred lectures, with the exception of Clinical Medicine and Clinical Surgery. The three months' courses must consist of not fewer than fifty lectures.

\*\* The following order of study is recommended as a guide to the student, though not enjoined. *First Year*—Anatomy; Practical Anatomy; Chemistry; Practical or Analytical Chemistry; Hospital. *Second Year*—Anatomy; Practical Anatomy; Physiology; Surgery; Materia Medica (the last either in this or the third year); Hospital. *Third Year*—Practice of Medicine; Clinical Surgery; Practical Anatomy; Practical Pharmacy; Clinical Medicine; Pathological Anatomy; Hospital. *Fourth Year*—Surgery or Clinical Surgery; Midwifery and Diseases of Women and Children; Practice of Medicine or Clinical Medicine; Medical Jurisprudence; Practical Midwifery; Hospital.

†† The examination will embrace the following subjects:—1. English language, including Grammar and Composition. 2. Arithmetic, including Vulgar and Decimal Fractions. Algebra, including Simple Equations. 3. Geometry: First Two Books of Euclid. 4. Latin: Cicero, *De Senectute* et *de Amicitia*; or Horace, *Carmina*, Lib. II and III. 5. One of the following subjects, at the option of the candidate:—1) Greek: Herodotus, *History*, Book I; and Homer, *Iliad*, Book II. (2) French:

dical Students.—Testimonials of proficiency granted by the educational bodies recognised by the Medical Council will be accepted as sufficient evidence of general education, and will exempt from the preliminary examination.—The preliminary examinations will take place on October 21st and November 4th, 1871, and on April 20th and July 20th, 1872.—Students who intend to undergo the preliminary examination must give in their names, addresses, and places of birth to the officer of either College, not later than two days before the day of examination; and must pay a fee of Ten Shillings, not to be returned in case of rejection; but they will be admissible to re-examination at a future period without paying another fee.—Candidates, the commencement of whose professional studies was prior to September 17th, 1866, may pass the preliminary examination in general education at any of the periods previous to the first professional examination, but are recommended to do so at the earliest possible period. Candidates under this regulation, who have not passed a preliminary examination in general education, will be admitted to a special examination in general education previously to their first professional examination. For this they pay a fee of £1.

#### Professional Examination.

1. Candidates for the double qualification are subjected to two professional examinations. 2. Opportunities for both examinations will be presented six times in each year. On each of these occasions, the candidates write answers to the questions proposed. The oral examinations are conducted on the days immediately succeeding. 3. Unsuccessful candidates are remitted to their studies for not less than three months. 4. The first examination embraces Anatomy, Physiology, and Chemistry; and takes place not sooner than the end of the second winter session. 5. Candidates who desire to pass this examination must apply to the Inspector of Certificates on or before the Saturday preceding the day of examination,\* and must produce tickets, and also certificates of attendance on those courses of lectures which have reference to the subjects of the examination, and evidence of having passed the preliminary examination. 6. The sum of £6 must be paid to the Inspector of Certificates for this examination, not later than 10 A.M. of the day preceding it. This sum will be considered as paid to account of the entire Fee of £16 payable for the two Diplomas. 7. In the case of a candidate being unsuccessful at this examination, £4 will be returned to him. 8. The second examination embraces Medicine, Surgery and Surgical Anatomy, Midwifery, Pathological Anatomy, Materia Medica and Pharmacy, and Medical Jurisprudence; and does not take place before the termination of the winter session of the last year of study. In the case of candidates who began their course of study after September 16th, 1866, it will not take place until four years after the examination in general education. 9. Applications for examination must be made to the Inspector of Certificates not later than the Monday previous to the day of examination. 10. Every candidate must produce to the Inspector—*a.* Satisfactory evidence of having attained the age of twenty-one years; *b.* A certificate of having passed the preliminary examination, unless this certificate have been already seen by the Inspector of the Colleges; *c.* A certificate of registration in the books of the General Medical Council; *d.* A certificate of having passed the first professional examination; *e.* The certificate of his classes, etc.; *f.* A tabular statement (for which a printed form will be furnished by the Inspector), exhibiting the full amount of his professional education, and distinguishing the classes, hospitals, and dispensaries attended during each session of his studies. 11. The fee payable for this examination, which is £10, must be lodged with the Inspector not later than 10 A.M. of the day preceding the examination-day. 12. On the production of the above documents, and after receiving the fees, the Inspector gives the candidate a letter authorising the examiners to take him on trial. 13. In case of a candidate being unsuccessful at the second examination, £8 will be returned to him. 14. Candidates who have passed the first professional examination in Anatomy, Physiology, and Chemistry, at any of the Licensing Boards recognised by the Medical Act, will be admissible to the second professional examination on producing certificates of the whole course of study prescribed, and of having passed their preliminary and first professional examinations. If any of the three subjects of the first examination have been omitted, such candidates will have to undergo an examination on the omitted subjects; and none of the subjects set down in § 8 will be omitted at the second

Voltaire's *Henriade*. (3) German: Schiller's *Wilhelm Tell*. (4) Natural Philosophy, including Mechanics, Hydrostatics, and Pneumatics. In Latin, Greek, French, and German, parsing of words from the passages given to be translated will be required; also, translation of short sentences from English into the respective languages.

\* Candidates at a distance are requested to send their certificates much earlier, so as to give sufficient time for the exchange of one or two explanatory letters; as much disappointment has been occasioned by the discovery of defects in their course of study when it was too late to rectify them by the production of documents.

examination, even if some of them should have formed part of the first examination by another Board. The fee payable by such candidates is £16, and unsuccessful candidates will receive back £14. 15. In addition to the written and oral examinations, all candidates shall be subjected to a practical Clinical Examination in Medicine and Surgery, which shall include the examination of patients, physical diagnosis, the use of the microscope, surgical appliances, bandages, etc. 16. Candidates desirous of special examination on other days than those fixed by the regulations must prepare a case to be submitted for the consideration of the authorities of the Colleges, with evidence to show why it was and is impossible for them to avail themselves of the ordinary examinations, past or future. They must at the same time produce certificates of the whole of the prescribed course of study and of the preliminary examination, and state the earliest and the latest days within which they can present themselves. It is very desirable that all such candidates, and especially those who are at a distance from Edinburgh, should present their applications as long beforehand as possible. An extra fee is required in such cases. 17. No candidate shall be admissible to examination who has been rejected by any other Licensing Board within the three months preceding his examination.

*Communications from candidates to be addressed to DR. GAIRDNER, Inspector and Treasurer of the Double Qualification, at 45, Northumberland Street, Edinburgh.*

The following will be the periods of examinations for the Double Qualification of the Royal Colleges of Physicians and Surgeons of Edinburgh, for the year 1871-72. *First Professional Examinations.*—Tuesdays, October 24th, 1871, January 23rd, April 2nd and 30th, July 9th and 23rd, October 22nd, 1872. *Second Professional Examinations.*—These will take place immediately after the conclusion of the first professional examinations, at each of the above mentioned periods. In no case will they be begun on an earlier day than the Thursday of any period, nor will they usually be later than that day.

## FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

### REGULATIONS FOR THE DIPLOMA.

THE Regulations respecting the Curriculum of Professional Study are similar to those of the Royal College of Surgeons of Edinburgh.

*Preliminary Examinations in General Literature* will be held on October 20th and November 3rd, 1871, and on April 26th, July 19th, October 18th, and November 1st, 1872.\* The Fee is Ten Shillings. Candidates are requested to give in their names to the Secretary at least two days before the examination, and to give intimation of the optional subject they select.

The *First Professional Examinations* take place on the second Tuesday every month. The *Second Professional Examinations* take place, the written part on the second Tuesday of every month, and the clinical and oral parts on the succeeding day.

The Fee is £10; viz., £4 for the first, and £6 for the second examination.

The examinations are conducted partly in writing and partly orally. Recent Dissertations, Anatomical Specimens, Chemical Tests, Articles of the Materia Medica, the Microscope, Surgical Apparatus, and Pathological Specimens are employed at the discretion of the examiners. Candidates are also subjected, at the second examination, to a practical Clinical Examination at the Hospital.

Candidates for the Diploma of the Faculty, who possess a qualification to practice, or who have passed the examination in Anatomy, Physiology, and Chemistry, before any of the Licensing Bodies enumerated in Schedule (A) of the Medical Act, on complying with the regulations in other respects, will be admitted to the second professional examination. In such cases, the full fee is exigible. In the case of unsuccessful candidates, £2 of the fee is retained.

A candidate, on showing a sufficient reason, may be admitted to examination on a day specially arranged, on paying an extra fee.

## ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

### DOUBLE QUALIFICATION IN MEDICINE AND IN SURGERY.

THE Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Physicians of Edinburgh, conjointly grant their Diplomas after one series of examinations before a Board of Examiners in which each body is represented. The regulations as to the curriculum of study are the same as those for the conjoined examinations of the Royal Colleges of Physicians and Surgeons of Edinburgh. The fee for the two diplomas granted conjointly is £16.

## UNIVERSITIES OF EDINBURGH, GLASGOW, ABERDEEN, AND ST. ANDREW'S.

### REGULATIONS RESPECTING DEGREES IN MEDICINE.

[THE Regulations of these Universities are nearly similar. We therefore give but one statement, noticing points of difference when necessary.]

Three Medical Degrees are conferred by each University; viz., Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The Degree of C.M. is not conferred on any person who does not also at the same time obtain the Degree of Bachelor of Medicine.

### Preliminary Education.

The preliminary branches of extra-professional education are English, Latin, Arithmetic, the Elements of Mathematics, and the Elements of Mechanics; and candidates must also pass a satisfactory examination in at least two of the following subjects:—Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy.\* The examinations on both classes of subjects take place† before the candidate has entered on his medical curriculum.‡

A Degree in Arts (not honorary) in any one of the Universities of England, Scotland, or Ireland, or in any Colonial or Foreign University specially recognised by the University Court, exempts from all preliminary education; [and an examination in Arts by any corporate

\* The Universities of Glasgow, Aberdeen, and St. Andrew's, include Natural History.

† As far as possible. —Aberdeen.—At Glasgow, the examination in the first class of subjects must take place before the commencement of the Medical Curriculum; and that in the second class previously to the first professional examination (as far as possible, previously to the commencement of professional study).

‡ In Edinburgh, examinations on these subjects will be held on 17th and 18th of October 1871, and 20th and 21st March 1872. 1. *English*.—A portion of an English author must be written to dictation; the grammatical construction of one or two sentences must be explained; the grammatical errors in a sentence ungrammatically composed must be pointed out, and their nature explained; and the derivation and definition of a few English words in common use must be given (see Bain's *English Grammar*, and Angus on the *English Language*). 2. *Latin*.—Ninth *Æneid* of Virgil, an easy passage from a Latin Prose Author, and a single passage of English translated from a Latin Author to be re-translated into Latin, the more difficult Latin words being given. 3. *Arithmetic*.—The Common Rules, including Decimals. 4. *Elements of Mathematics*.—Euclid, Books I, II, and III; and the Rudiments of Algebra, including Simple Equations. A knowledge of Euclid alone will not be sufficient. 5. *Elements of Mechanics*.—Elementary Mechanics and Hydrostatics.—At the same date, examinations will also take place in the additional subjects, as follows: 1. *Greek*.—Fourth Book of Xenophon's *Anabasis*. 2. *French*.—Voltaire's *Henriade* (xiv). 3. *German*.—Schiller's *Death of Wallenstein*. 4. *Higher Mathematics*.—Euclid, Books I to VI; Algebra, Trigonometry, and Conic Sections. 5. *Natural Philosophy*.—Balfour Stewart's *Elementary Physics*. 6. *Logic*.—Fowler's *Elements of Deductive Logic*. 7. *Moral Philosophy*.—Stewart's *Outlines of Moral Philosophy*, Part II, with McCosh's Notes.

In Glasgow, examinations will take place on October 13th, 1871, and April 15th, 1872, as follows. *First of Elementary Part*, Exercises in all of which are required. *English*.—Writing correctly a passage to dictation; Composition of a short Essay on a given theme; Questions in Grammar. *Latin*.—Third Book of the *Æneid* of Virgil, and Fourth Book of *Caesar De Bellis Gallicis*; Translations of passages from authors not prescribed, and of English passages into Latin, the principal Latin words being supplied. Questions in Grammar and Construction. *Arithmetic*.—The Common Rules, including Vulgar and Decimal Fractions. *Elements of Mathematics*.—Euclid, Books I, II, and III; Algebra, as far as Simple Equations. *Elements of Mechanics*.—Questions, for which such works as Todd's *Elementary Mechanics* may serve as text books. *Second Part*, Exercises in two of which, to be selected by the candidate, are required. *Greek*.—*Anabasis* of Xenophon, Book I, and the Gospel according to St. John; Translation of passages from Greek authors not prescribed, and of English passages into Greek, the principal Greek words supplied; Questions in Grammar. *French*.—Voltaire's *Charles XII*; Translations and exercises as in Latin and Greek. *German*.—Schiller's *Wallenstein* (iv); Translations and exercises as in the other languages. *Mathematics*.—Euclid, Books I to VI; Algebra, including Quadratic Equations, and the Rudiments of Trigonometry. *Natural Philosophy*.—Such a knowledge of the principles as may be obtained from the Text books of Golding Bird and Brewster, and Gould. *Natural History*.—Geology or Zoology. Text books, Jukes, Lyell, Dana, R. Jones, Dallas, Milne Edwards, Leach, Whitley's *Logic*, Books II and III. *Moral Philosophy*.—The General Principles, as stated in Dugald Stewart on the Active Powers, or Dr. Fleming's Manual.

body, whose examination has been recognised by the General Medical Council, and also approved by the University Court, shall exempt from preliminary examination in Arts on all subjects comprised in the examination of the said corporate body.]\*

#### *Degree of Bachelor in Medicine and Master in Surgery.*

Candidates for the Degree of Bachelor of Medicine or Master in Surgery must have been engaged in medical and surgical study for four years—each *Annus Medicus* being constituted by at least two courses of not less than 100 lectures each, or by one such course, and two courses of not less than 50 lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week.

Every candidate for the degrees of M.B. and C.M. must give sufficient evidence by certificates—1. That he has studied Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine and of Surgery, Midwifery and the Diseases of Women and Children,† General Pathology,‡ during courses including not less than 100 Lectures; Practical Anatomy, a course of the same duration as the preceding; Practical Chemistry, three months; Practical Midwifery, three months at a Midwifery Hospital, or attendance on six cases under a registered medical practitioner; Clinical Medicine and Clinical Surgery, each course of not less than 100 lectures or two courses of three months; Medical Jurisprudence, Botany, Natural History, including Zoology, courses of not less than 50 Lectures. 2. That he has attended for at least two years, the Medical and Surgical Practice of a General Hospital with not fewer than eighty patients. 3. That he has been engaged for at least three months in compounding and dispensing drugs at the Laboratory of a Hospital or Dispensary, Member of a Surgical College or Faculty, Licentiate of the London or Dublin Society of Apothecaries, or a Member of the Pharmaceutical Society of Great Britain. 4. That he has attended, for at least six months, the out-practice of a hospital or the practice of a dispensary, or of a registered practitioner. Evidence of a practical knowledge of vaccination is also required.

One of the four years of medical and surgical study must be in the University granting the degree sought. Another year must be either in the same University, or in some other University entitled to give the Degree of Doctor of Medicine.¶ [At St. Andrew's, no one can be received as a candidate for the Degree of Bachelor of Medicine or Master in Surgery unless two years at least of his four years of medical and surgical study shall have been in one or more of the following Universities and Colleges; viz., the Universities of St. Andrew's, Glasgow, Aberdeen, Edinburgh, Oxford, or Cambridge; Trinity College, Dublin; and Queen's College, Belfast, Cork, or Galway.] Attendance during at least six winter months on the medical or surgical practice of a General Hospital which accommodates at least eighty patients, and, during the same period, on a course of Practical Anatomy; and one year's attendance, to the extent of four of the departments of medical study required, on the lectures of teachers of Medicine in the hospital schools of London, or in the school of the College of Surgeons in Dublin, or of such teachers of Medicine in Edinburgh or elsewhere as shall from time to time be recognised by the Edinburgh University Court, may be reckoned as one of the four years.¶ All candidates not students of the University of Edinburgh, availing themselves of the permission of attending the lectures of Extra-Academical Teachers in Edinburgh, must, at the commencement of each year of attendance, enrol their names in a book to be kept by the University for that purpose, paying a fee of the same amount as the Matriculation Fee.

Every candidate must deliver, before the 31st day of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine—1. A declaration, in his own handwriting, that he is 21 years of age, or that he will be so on or before the day of graduation; and that he will not be, on the day of graduation, under articles of apprenticeship. 2. A statement of his studies, general and professional, accompanied with proper certificates.\*\*

\* This portion, enclosed in brackets, is in the Regulations of the University of Edinburgh alone.

† Two courses of Midwifery, of three months each, are reckoned equivalent to a six months' course, provided different departments of Obstetric Medicine be taught in each of the courses.

‡ Or a three months' course of lectures on Morbid Anatomy, together with a supplemental course of Practice of Medicine or Clinical Medicine.

§ In the Laboratory of an Hospital or Dispensary, of a Registered Medical Practitioner, or of a Member of the Pharmaceutical Society of Great Britain.—Glasgow.

¶ Entitled to grant Degrees in Medicine.—Glasgow.

¶ The other two years may be constituted by attendance upon courses in the great Hospital Medical Schools of London or Dublin; and, in default of such attendance, one of the four years may be constituted by attendance on any general Hospital containing not less than eighty beds, provided attendance has been given at the same time on a course of Practical Anatomy.—Glasgow.

\*\* The Universities of Aberdeen and St. Andrew's require an Inaugural Dissertation to be presented previously to the final examination for M.B. In Edinburgh and Glasgow, no Thesis is now required until the candidate seeks the Degree of M.D.

Each candidate is examined in writing and *visu voce*—1, on Chemistry, Botany, and Natural History; 2, on Anatomy, Institutes of Medicine, Materia Medica (including practical Pharmacy), and Pathology; 3, on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence; 4, Clinically on Medicine and on Surgery in a Hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, Materia Medica and Pathology, are conducted, as far as possible, by demonstrations of objects. Students may be admitted to examination on the first division of these subjects at the end of their second year, and on the second division at the end of their third year. The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *Annus Medicus*. Candidates may be admitted to examination on the first two of these divisions at the end of their third year, or to the four examinations at the end of the fourth year. If any candidate be found unqualified, he cannot be again admitted to examination unless he has studied during another year two of the prescribed subjects, either in the University or in some other school of medicine.

[The above are the regulations, regarding professional examination, of the University of Edinburgh. Those of the other three Universities differ somewhat from those of Edinburgh. They are as follows.]

Every candidate for the Degrees of Bachelor of Medicine and Master in Surgery shall undergo three professional examinations, which will be conducted in writing and *visu voce*. The first examination (not to be taken before the end of the second year of study) to include Chemistry, Elementary Anatomy, and Botany.\* The second examination (not to be taken before the end of the third year) to include advanced Anatomy, Physiology, and Zoology with Comparative Anatomy.† The third examination (not to be taken before the end of the fourth year) to include Materia Medica, General Pathology, Surgery, Practice of Medicine, Midwifery, Medical Jurisprudence, Clinical Medicine, and Clinical Surgery.‡ The examinations in Anatomy, Chemistry, Physiology, Botany, Zoology, and Materia Medica, will be conducted, as far as possible, by demonstrations of objects exhibited to the candidates; and those on Medicine and Surgery, in part, by clinical demonstrations. Candidates may be admitted to examination on the first two of these divisions at the end of the third year, or to the three examinations at the end of their fourth year. If any candidate be found unqualified, he shall not be again admitted to examination unless he shall have completed another year of medical study, or such portion of another year as may be prescribed by the examiners.]

#### *Degree of Doctor of Medicine.*

The Degree of Doctor of Medicine may be conferred on any candidate who has obtained the Degree of Bachelor of Medicine, and is of the age of 24 years, and has been engaged, subsequently to his having received the degree of Bachelor of Medicine, for at least two years in attendance on a Hospital, or in the Military or Naval Medical Services, or in Medical and Surgical Practice. The candidate must be a Graduate in Arts, or must, before or at the time of his obtaining the degree of Bachelor of Medicine, or within three years thereafter, have passed a satisfactory examination in Greek, and in Logic or Moral Philosophy, and in one at least of the following subjects: viz., French, German, Higher Mathematics, and Natural Philosophy.§ He must submit to the Medical Faculty a Thesis composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degree of Bachelor of Medicine, which he may have made a subject of study after having received that degree.

Candidates who commenced their medical studies in Edinburgh before February 4th, 1861, and in Aberdeen before November 1861, are entitled to be examined for the degree of Doctor of Medicine, without previously taking that of Bachelor of Medicine, under the regulations then in force in each University respectively.

The Degree of Doctor of Medicine may be conferred by the University of St. Andrew's on any Registered Medical Practitioner above the age of 40 years, whose professional position and experience are such as, in the estimation of the University, to entitle him to that Degree, and who shall, on examination, satisfy the Medical Examiners of the sufficiency of the professional knowledge, provided always that degrees shall not be conferred under this section on a greater number than ten in any one year.

The Graduation Fees in each of the Universities are—for the Degree of M.B., three Examinations, each £5:5=£15:15; for the Degree

\* And Materia Medica.—St. Andrew's.

† And Surgery.—St. Andrew's.

‡ Materia Medica and Surgery in the two previous examinations.—St. Andrew's.

§ In Greek and in Logic or Moral Philosophy, and in any one of the other optional subjects in the examination in General Education.—Glasgow. Natural History added in optional subjects.—St. Andrew's.

of C.M., £5:5 additional; for the Degree of M.D., £5:5 additional to that for M.B., together with Government Stamp Duty (£10).

The fee for graduating under the old Regulations in Edinburgh is £25; at St. Andrew's, the fee for the Degree of M.D. under the section relative to Registered Medical Practitioners is 50 Guineas. Stamp Duty is included in both cases.

## KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

### REGULATIONS RELATIVE TO THE LICENCE IN MEDICINE.

EXAMINATIONS for the Licence in Medicine are held on the second Wednesday in each month (except August and September). The name of every candidate, together with his schedule and the documents hereafter mentioned, must first be submitted to the College at one of its meetings. These are held regularly on the first Friday in each month (except August and September), and no name can be received later than the Monday previous to such meeting. If permission to be examined be granted, the candidate may present himself at the next examination, or at a subsequent one: in the latter case, however, he must intimate his intention three clear days before the examination.

A candidate who has not, previously to entering his name, obtained any medical or surgical qualification recognised by the College, must produce certificates—1. Of having been engaged in the study of Medicine for four years. 2. Of having passed the preliminary examination of one of the recognised Licensing Corporations before the termination of the second year of medical study. 3. Of having studied at a school or schools recognised by the College the following subjects; Practical Anatomy; Anatomy and Physiology, or Institutes of Medicine; Botany; Chemistry; Practical Chemistry; Materia Medica; Practice of Medicine and Pathology; Surgery; Midwifery; Medical Jurisprudence. 4. Of having attended a Medico-Chirurgical Hospital in which regular courses of Clinical Lectures are delivered, together with clinical instruction, for twenty-seven months, or such hospital for eighteen months, with nine months at a medical hospital. 5. Of having attended Practical Midwifery for six months at a recognised Lying-in Hospital, or evidence satisfactory to the College of having attended Practical Midwifery. 6. Of character, from two registered physicians or surgeons. A candidate who has already obtained a medical or surgical qualification recognised by the College, is required to fill up a schedule which will be supplied on application, and to lodge it in the same manner, as a candidate not previously qualified; but the only documents which he is required to produce are his diploma or certificate of registration, and the certificate of Practical Midwifery, and testimonials as to character.

The examination is conducted, first by printed questions, to be answered in writing, and afterwards *viva voce*, and consists of two parts:—1. Anatomy; Physiology; Botany; Chemistry. 2. Materia Medica; Practice of Medicine; Medical Jurisprudence; Midwifery. Candidates will also be examined at the bedside.

Candidates qualified as follows are required to undergo the *second part of the professional examination only*; viz.—1. Graduates in Medicine of an University in the United Kingdom, or of any Foreign University approved by the College. 2. Fellows, Members, or Licentiates of the Royal Colleges of Physicians of London or Edinburgh, who have been admitted upon examination. 3. Graduates or Licentiates in Surgery. 4. Candidates who, having completed the curriculum above mentioned, have passed the previous examination of any of the Licensing Corporations in the United Kingdom. Physicians or surgeons of five years' standing are further exempted from the written portion of the final examination. Fee for Licence in Medicine, £15:15.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

### REGULATIONS REGARDING DIPLOMAS.

REGISTERED pupils are admitted to the preliminary examination at any period previous to the Final Examination for Letters Testimonial. Students who are not registered pupils are also admitted to answer the preliminary examination upon payment of ten shillings; but they are not enrolled as registered pupils, or entitled to the privileges of such pupils, until they have paid the full registration fee of Five Guineas.\*

\* The following are the subjects on which candidates for the Preliminary Examination will be examined in: The English Language, including Grammar and Composition; Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations; Geometry, including the Elements of Euclid, Latin and Greek, in which the Translation and Composition in Greek; The Elements of Latin, the Metaphysics of Aristotle, and the First Book of Metaphysics of Aristotle. In Latin—The First and Second Books of the *Æneid* of Virgil, the *Jugurthine War* of Livy, or the Third Book of Livy.

No student is admitted as a candidate to the quarterly examination, or to the final examination for letters testimonial, until he has been enrolled as a registered pupil.

### Letters Testimonial.

Every registered pupil shall be admitted to an examination for Letters Testimonial if he shall have laid before the Council the following documents:—A receipt showing that he has lodged a sum of £21 in the Bank of Ireland to the credit of the President, and for the use of the College, and certificates that he has passed an examination in the Greek and Latin Languages, and that he has been engaged in the study of his profession for not less than four years.

Examinations are held quarterly, commencing on the second Tuesday in January, April, July, and October, at which candidates are divided into two classes—Junior and Senior. The junior class must produce certificates of having attended three courses each of Lectures on Anatomy and Physiology, and on Practical Anatomy with Dissections; two courses of Lectures on Chemistry; one course each of Lectures on Materia Medica, Botany, and Forensic Medicine. This class is examined in Anatomy, Physiology, and Materia Medica. The senior class must produce certificates of having attended three courses of Lectures on the Theory and Practice of Surgery, and one course each of Lectures on the Practice of Medicine, and of Lectures on Midwifery; also certificates of attendance on a recognised hospital for three winter and three summer sessions. This class is examined in Surgery, Operative Surgery, the Practice of Medicine, and forms of Prescription.

Candidates for Letters Testimonial or Fellowship of the College, being Licentiates of a College of Physicians or Graduates in Medicine of an University, are examined in General and Descriptive Anatomy, Physiology, the Theory and Practice of Surgery, and Operative Surgery; and, if recommended to the Council for admission as Licentiates, are admitted by the Letters Testimonial. The examinations are both oral and written. Candidates, whose answering shall be found insufficient, will not be allowed to present themselves a second time until after six months from their first examination.

The fee for the junior examination is £5:5; for the senior, £15:15; making, with the preliminary examination fee (10s.) and registration fee (£5:5), a total of £26:15 for Letters Testimonial. Every candidate rejected at the quarterly examination must pay £2:2 on applying for re-examination.

### Fellowship.

Every registered pupil or licentiate may be admitted to examination for the Fellowship on producing a certificate that he is 25 years of age, and that he is a Bachelor of Arts, or has been examined with a view to ascertain that he has obtained a liberal preliminary education; also a certificate, signed by two or more Fellows of the College, of good general conduct. He must have been engaged in the acquisition of professional knowledge not less than six years (five years being required in the case of Bachelors of Arts), during three of which he must have studied in one or more of the schools and hospitals, recognised by the Council. The other three years may have passed in any approved school. He must also have acted as House-Surgeon or Dresser in a recognised hospital; and must have attended the lectures required of candidates for Letters Testimonial, together with one course of lectures on Comparative Anatomy, and one on Natural Philosophy. He must present a thesis on some medical subject, or clinical reports, with observations of six or more medical or surgical cases taken by himself.

Licentiates of the College, who may not be able to show that they have followed the course of study specified in the regulations, may, at the expiration of ten years from the date of their Diploma, be admitted to the examination for the Fellowship, on producing satisfactory evidence that they have conducted themselves honourably in the practice of their profession.

Each candidate for the Fellowship is examined on two days. The subjects of the first examination are Anatomy and Physiology (Human and Comparative); those of the second—Pathology, Therapeutics, the Theory and Practice of Medicine and Surgery, and such other branch of medical science as the Council may, from time to time, direct. The examinations are both oral and written. The candidates must perform Dissections and Operations on the dead body. Rejected candidates cannot present themselves a second time until after one year from the first examination.

The Fee payable is £21 if the candidate be a Licentiate, or £36:15 if he be a registered pupil; provided in either case he intends to reside beyond ten miles from Dublin. Should the candidate intend to reside in Dublin, or within ten miles thereof, he pays, if a Licentiate, £31:10; if a registered pupil, £47:5. Fellows entering on the country list, who may subsequently settle as Practitioners in Dublin, or within ten miles thereof, must pay £10:10 to the College.

## APOTHECARIES' HALL OF IRELAND.

## REGULATIONS REGARDING THE LICENCE TO PRACTISE.

EVERY candidate for the Licence to practise is required to undergo a Preliminary and a Professional Education and Examination.\* The Arts Examination will be held on the third Thursday in January, April, July, and October, at 12 noon. Answers in writing must be given to printed questions. Unsuccessful candidates will be remitted to their studies for six months.

*Professional Education and Examination.*

Every candidate for the Licence must produce certificates:—1. Of having passed an examination in Arts previously to entering on professional study. 2. Of being at least 21 years of age, and of good moral character. 3. Of apprenticeship to a qualified apothecary, or of having been engaged at practical pharmacy with an apothecary for a period of three years subsequent to having passed the examination in Arts. 4. Of having spent four years in professional study. 5. Of having attended the following courses; viz., Chemistry, Principles and Practice of Medicine, and Surgery, each during one winter session; Anatomy and Physiology, Demonstrations and Dissections, each during two winter sessions; Botany and Natural History, and Forensic Medicine, each during one summer session; Practical Chemistry (in a recognised Laboratory) and Practical Pharmacy, each during three months; Midwifery and Diseases of Women and Children, during six months; Practical Midwifery at a recognised Hospital (twenty cases); instruction in vaccination. 6. Of having attended, at a recognised hospital or hospitals, the Practice of Medicine and Clinical Lectures on Medicine, during two winter and two summer sessions; also the Practice of Surgery and Clinical Lectures on Surgery, during one winter and one summer session. 7. Of having performed vaccination successfully under a recognised vaccinator.

The examination for the Licence to practise is divided into two parts. The first part comprehends Chemistry, Botany, Anatomy, Physiology, and Pharmacy. The second—Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene. The first part may be undergone at the close of the second winter session; and the second at the termination of the fourth winter session.

The examinations will be held on the first and second Mondays in January, April, July, and October.

Candidates who fail to pass the first part of the professional examination will be remitted to their studies for three months. Unsuccessful candidates at the pass examination will not be re-admitted until after six months.

## UNIVERSITY OF DUBLIN.

## DEGREES AND LICENCES IN MEDICINE.

THE degrees in Medicine and Surgery granted by the University are: 1. Bachelor of Medicine; 2. Doctor of Medicine; 3. Master in Surgery. It also grants Licences in Medicine and Surgery.

*Bachelor in Medicine.*

A candidate for the Degree of Bachelor in Medicine must be a Graduate in Arts, and may obtain the Degree of Bachelor in Medicine at the same commencement as that at which he receives his Degree of B.A., or at any subsequent commencement, provided the requisite medical education shall have been completed. The medical education is of four years' duration, and comprises attendance on a course of each of the following lectures: *Winter*—Anatomy; Practical Anatomy; Theoretical and Operative Surgery; Chemistry; Practice of Medicine; Midwifery. *Summer*—Botany; Institutes of Medicine; Materia Medica and Pharmacy; Medical Jurisprudence. *Term Courses*—Heat (Michaelmas); Electricity (Hilary); Magnetism and Comparative Anatomy (Trinity). Two courses of nine months' attendance on the clinical lectures of Sir Patrick Dun's or other metropolitan hospital recognised by

the Board.\* Six months' instruction in practical Midwifery,† including clinical lectures. A certificate of personal attendance on fever cases, with names and dates of cases. Six months' dissection, and three months' laboratory instruction in Chemistry. Any of the winter or summer courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows.‡ The Fee for the *Licent ad Examinandum* is £5; for the Degree of M.B., £11.

*Doctor in Medicine.*

A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must perform exercises for the degree before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this Degree, £13.

*Master in Surgery.*

The Degree of Master in Surgery can only be obtained by students who are Bachelors of Arts, and who have completed the professional curriculum, and passed the examinations required. The curriculum comprises the following, in addition to the complete course for the M.B. Degree: Theoretical and Operative Surgery, one course; Dissections, two courses; Ophthalmic Surgery, one course; Nine months in Sir Patrick Dun's or other recognised metropolitan hospital, with clinical lectures. Attendance on the practice of a recognised county infirmary for two years previously to the commencement of medical study in Dublin, is allowed to count as one year of hospital attendance. Candidates are required to perform surgical operations on the dead subject. Candidates for the Degree of Master in Surgery, who have already passed the examination for the Degree of Bachelor in Medicine, will be examined in Anatomy and Surgery only. Fee for the *Licent ad Examinandum*, £5; for the Degree of M.Ch., £11.

*University Licences.*

Candidates for the Licences in Medicine or Surgery must be matriculated in medicine, and must have completed two years in Arts and four years in medical studies.

In case the student should wish to continue the undergraduate course in Arts, with a view to the Degree of B.A., his answering in the matriculation examination§ will be reckoned as equivalent to the entrance examination and the Hilary examination of the Junior Freshman year.

The medical course and examination for the Licence in Medicine is the same as for the Degree of M.B. A Licentiate in Medicine, on completing his course in Arts, and proceeding to the Degree of B.A., may become a Bachelor in Medicine, on paying the Degree fees, without further examination in medicine. Fee for the *Licent ad Examinandum*, £5; for the Licence in Medicine, £5.

The surgical course and examination necessary for the Licence in Surgery, are the same as for the Degree of Master in Surgery. Fee for the *Licent ad Examinandum*, £5; for the Licence in Surgery, £5.

*Examinations.*

Candidates for Degrees and Licences in Medicine and Surgery are required to pass an examination in the following subjects previously to their Degree examination: Descriptive Anatomy; Botany, Materia Medica and Pharmacy; Chemistry; and Physics. Two Medical Scholarships, of £20 each for two years, are awarded to the best answers at the previous examinations, on certain conditions. Candidates for Degrees and Licences in Medicine and Surgery are examined at the bedside.

*Qualifications in State Medicine.*

Doctors of Medicine, who wish to obtain from the University a certificate of qualification in State Medicine, can do so on passing an

[Continued at page 300.]

\* The following Hospitals are recognised:—1. Sir Patrick Dun's Hospital; 2. Meath Hospital; 3. House of Industry Hospitals; 4. Dr. Steevens' Hospital; 5. Jervis Street Infirmary; 6. City of Dublin Hospital; 7. Mercer's Hospital; 8. St. Vincent's Hospital; 9. Adelaide Hospital; 10. Mater Misericordiae Hospital.

† Certificates of Practical Midwifery are received from 1. the Rotundo Hospital; 2. the Coombe Hospital; 3. Sir P. Dun's Hospital Maternity; 4. Dr. Steevens' Hospital Maternity.

‡ The following schools, in addition to the School of Physic of Trinity College, are recognised:—1. The School of the Royal College of Surgeons in Ireland; 2. The Carmichael School; 3. The School of Dr. Steevens' Hospital. 4. The St. Peter Street School; 5. The School of the Catholic University. The recognition is conditional on the students being furnished with *bona fide* certificates of regular attendance equivalent to that required by the University; i.e., three-fourths of the entire Lectures in each course.

§ The following are the subjects of examination. Homer's *Iliad*, Books I, II, (omitting Catalogue of Ships), III; Lucian's *Dialogues* (Walker's edition); Xenophon's *Anabasis*, Books I, II, III; Virgil, *Æneid*, Books I, II, III; Sallust; Horace, *Satires*; Latin Prose Composition; English Prose Composition; English History; Modern Geography; Arithmetic; Algebra, to the end of Simple Equations; Euclid, Books I, II, III.

\* The following are the subjects of Preliminary Examination:—*Compulsory*. 1. *English*: Grammar, Composition, writing from Dictation, the Roman History (the Punic Wars), and the English History (the reign of George I to the end of George III). 2. *Arithmetic and Algebra*: Arithmetic, including Vulgar and Decimal Fractions; Algebra, including Simple Equations. 3. *Geometry*: First Two Books of Euclid. 4. *Latin*: the Twenty-first Book of Livy, the First Three Books of the *Æneid* of Virgil, the First Two Books of the *Odes* of Horace (any two of the three). 5. *Greek*: the First Two Books of the *Anabasis* of Xenophon, the Ninth Book of the *Iliad* of Homer, the *Ajax* of Sophocles (any two of the three). 6. *French*: *Charles XII*, *Histoire de Vie* of Voltaire, or *Voyage en Orient* of Lamartine, or *Picciola* of Saintine. 7. *German*: *Wilhelm Tell* or *Die Rauber* of Schiller. Candidates will be examined in either French or German, as they may select.—*Optional*. 1. *Natural Philosophy*: Mechanics, Hydrostatics, and Pneumatics. 2. *Natural History*: The Classification, Elementary Structure, and General Physiology of Vegetables and Animals.

examination in a limited course of the following subjects: 1. Law; 2. Engineering; 3. Pathology; 4. Vital and Sanitary Statistics; 5. Chemistry; 6. Meteorology; 7. Medical Jurisprudence.

### QUEEN'S UNIVERSITY IN IRELAND.

THIS University grants the Degrees of Doctor in Medicine and Master in Surgery. It includes three Colleges—the Queen's Colleges of Belfast, Cork, and Galway—each of which possesses a Faculty of Medicine. The curriculum of medical study extends over a period of four years, and is divided into two periods of two years each. The first period comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy, *Materia Medica* and Pharmacy. The second period comprises attendance on Anatomy and Physiology, Practical Anatomy, Theory and Practice of Surgery, Midwifery and Diseases of Women and Children, Theory and Practice of Medicine, Medical Jurisprudence. At least two of the above courses of lectures must be attended in some one of the Queen's Colleges; the remainder may be taken, at the option of the candidate, in any University, College, or School, recognised by the Senate of the Queen's University. Candidates are required before graduating to have also attended in one of the Colleges of the Queen's University Lectures on Experimental Physics and on one Modern Language, and to have passed the Matriculation Examination. They are further required to attend, during the first period, Practical Chemistry in a recognised laboratory, and the practice during six months of a recognised Medico-Chirurgical Hospital, containing at least sixty beds, together with clinical lectures delivered therein; and to have attended, during the second period, a recognised Midwifery Hospital, with the clinical lectures therein delivered, for a period of three months; or a Midwifery Dispensary for the same period; or ten cases of labour, under the superintendence of the medical officer of any hospital or dispensary where cases of labour are treated; and eighteen months' practice of a recognised Medico Chirurgical Hospital containing at least sixty beds, and in which clinical instruction is delivered.

There are two University examinations—one comprising the subjects of study in the first period, the other the subjects of the second period. The University examinations are held twice in each year, in June and September. Candidates who commence their medical studies elsewhere are admitted to the first University examination before proceeding to College. Further information will be found in the *Queen's University Calendar*; or may be obtained by application to the Secretary, Queen's University, Dublin Castle.

### THE ARMY AND NAVY MEDICAL SERVICES.

The Regulations to be observed by candidates for admission to the medical Services of the Army or Navy are identical, with a few slight exceptions.

1. Every candidate desirous of presenting himself for admission to the Army or Navy Medical Service must be unmarried, and not under 21 nor over 28 years of age. He must produce a certificate from the district Registrar, in which the date of birth is stated; or if this cannot be obtained, an affidavit from one of the parents or other near relative, who can attest the date of birth, will be accepted. He must also produce a certificate of moral character [from the parochial minister, if possible].\*

2. The candidate must make a declaration that he labours under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer in any climate.† He must also attest his readiness to engage for general service, and to proceed on foreign service when required to do so.

3. The candidate must be registered under the Medical Act of 1858 as licensed to practice Medicine and Surgery in Great Britain or Ireland.

4. Certificates of registration, character, and age, must accompany the schedule when filled up and returned.

5. Candidates will be examined by the Examining Board in the following subjects: Anatomy and Physiology; Surgery; Medicine, including Therapeutics, the Diseases of Women and Children, Chemistry

\* Army Regulations.

† His personal fitness will be determined by a Panel of Medical Officers, who are required to certify that the candidate's fitness is sufficiently good to enable him to perform any and all operations without the aid of sedatives. [A candidate desirous of preparing himself for the performance of operations, in which it is not necessary the use of chloroform during the performance of operations, and thus to undergo the strain of the system.] Every candidate must also be free from organic disease of any organ, and from constitutional weakness or other disability likely to unfit him for military or naval service in any climate.

and Pharmacy, and a practical knowledge of drugs. (The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside.) The eligibility of each candidate for the Army or Navy Medical Service will be determined by the result of the examinations in these subjects only. Candidates who desire it will be examined in Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany with special reference to *Materia Medica*, and the number of marks gained in these subjects will be added to the total number of marks obtained in the obligatory part of the examination by candidates who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of these branches of science.\*

6. After passing this examination, every candidate will be required to attend one entire course of practical instruction in the Medical School at Netley, on—1. Hygiene; 2. Clinical and [Naval and†] Military Medicine; 3. Clinical and [Naval and†] Military Surgery; 4. Pathology of Diseases and Injuries incident to [Naval and†] Military Service.

7. At its conclusion, the candidate will be required to pass an examination on the subjects taught in the school. If he give satisfactory evidence of being qualified for the practical duties of an Army or Naval Medical Officer, he will be eligible for a Commission as Assistant-Surgeon.

8. During the period of his residence at the Netley Medical School, each candidate will receive an allowance of 5s. *per diem* with quarters, or 7s. *per diem* without quarters, to cover all costs of maintenance; and he will be required to provide himself with uniform (viz., the Regulation undress uniform of an Assistant-Surgeon, but without the sword).

9. All candidates will be required to conform to such rules of discipline as the Senate may, from time to time, enact.

[10. After completing three years' full-pay service, Assistant-Surgeons will be allowed to be examined for the rank of Surgeon, but no Assistant-Surgeon can be promoted to the rank of Surgeon until he shall have served five years, two of which must have been in a ship actually employed at sea.†]

### NOTES CONCERNING THE HOSPITALS AND MEDICAL SCHOOLS IN LONDON.

In addition to the Tables of the Classes, etc., and hours of attendance, given at pages 298 and 299, we subjoin Abstracts of the Programmes issued by the several Medical Schools. We have extracted those points of information which are of most interest to the student, in addition to those given in the tables. It will be seen, that many of the Schools make arrangements by which the course of instruction required by the Examining Boards for the general practitioner can be compounded for, by paying a sum either at once or in periodical instalments. For the information of those who may wish to attend separate classes in any school for one or more sessions, we give the respective fees demanded in each school. To avoid repetition, and save space, the titles of the classes are indicated by letters, thus:

- |                                      |                                       |
|--------------------------------------|---------------------------------------|
| a. Anatomy and Physiology.           | k. Forensic Medicine.                 |
| b. Descriptive and Surgical Anatomy. | l. Practical Chemistry.               |
| c. Anatomical Demonstrations.        | m. Comparative Anatomy.               |
| d. Chemistry.                        | n. Pathology and Morbid Anatomy.      |
| e. Medicine.                         | o. Dental Surgery.                    |
| f. Surgery.                          | p. Ophthalmic Surgery.                |

| i. Botany.                           | l.p. Hospital Practice.               |

ST. BARTHOLOMEW'S HOSPITAL.—Aggregate Fee, £105, in three instalments of £36 15s. each in the first winter, first summer, and second winter.—For general subjects for students of Dental Surgery, £52 10s.; or, first winter, £26 5s.; first summer, £26 5s.—Separate Classes: a and b, single, £7 7s.; perpetual, £10 10s.; c, one course, £3 3s.; one session, £5 5s.; d, e, f, r, single, £5 5s.; perpetual, £7 7s.; g, h, single, £5 5s.; perpetual, £6 6s.; i, k, single, £3 3s.; perpetual, £4 4s.; l, single, £2 2s.; m, o, p, single, £2 2s.; perpetual, £3 3s. (the lectures on Dental and on Ophthalmic Surgery are free to students of the Hospital); q, one course, £4 4s. l.p., Medical—6 months, £12 12s.; 2 years, £18 18s.; unlimited, £26 5s. Surgical—6 months, £15 15s.; 12 months, £21; unlimited, £26 5s. House-Phys-

\* [Marks will also be given to candidates who are willing to pass an examination in French or German. *Army.*]

† Naval Medical Service.

sicianships and House-Surgeons, £26 5s. Dresserships—3 months, £12 12s.; 6 months, £18 18s.; 12 months, £26 5s.

The Anatomical Museum, and the Museum of Materia Medica and of Botany, are open to students daily from 10 A.M. to 4 P.M.—The Reading Room is open every day; during winter, from 10 to 5; summer, 9 to 5; vacations, 10 to 2.30. Subscription to Library, one year, £1 1s.; 4 years, £2 2s.

*College.*—Students are admitted to residence in the College on the recommendation of a medical officer of the Hospital, which may be obtained on adducing satisfactory evidence of good moral character. The entrance-fee is £2 2s. All information regarding the College may be obtained on application to the Warden, Mr. W. Morratt Baker.

*Exhibitions, Scholarships, and Prizes.*—Jeaffreson Exhibition, founded 1868: £20 yearly, tenable for two years. Confined to students of less than six months' standing. Examination on October 18, 1871: Subjects, those of Preliminary Education appointed by the General Medical Council.—Seven Scholarships are awarded. Two senior scholarships, value £50 and £25, in Medicine, Surgery, and Midwifery. Two senior scholarships, of the same value, in Anatomy, Physiology, and Botany. Three junior scholarships, of the value of £50, £30, and £20, will be awarded after the general examinations at the end of the summer and winter sessions.—Wix Prize, for the best essay on "The Connexion between Revealed Religion and Physical Science."—Hichens Prize: subject of examination, Bishop Butler's *Analogy*.—Bentley Prize, for the best report of not less than twelve surgical cases occurring in the wards of the hospital during the previous year.—Foster Prize, for Practical Anatomy—Senior.—Treasurer's Prize, for Practical Anatomy—Junior.—The Kirkes Gold Medal for Clinical Medicine.—The conditions under which the exhibitions, scholarships, and prizes are awarded, will be found in the prospectus of the College.

*Appointments.*—Four House-Physicians and four House-Surgeons (who must be qualified to practise) are appointed annually. Fee, £26 5s. Each of these officers is provided with rooms, and receives a salary of £25. Two Midwifery Assistants are appointed every six months, and are provided with rooms.—Sixteen Dressers to the surgical in-patients and the surgical casualty department are selected each year from the students of the second year. Other dresserships may be obtained by payment of the usual fees.—The Clinical Clerks to the medical in-patients, and the Clerks to the Physician-Accoucheurs, are chosen from the most diligent students.—There are also Clerks to the Assistant-Physicians and the Assistant-Surgeons in the special departments.

All first year's students are arranged in classes, and are required to attend the surgical wards. Elementary practical instruction is given by the Assistant-Physician in the medical wards.

*Examinations.*—Students preparing for their examinations are arranged in classes, and examined by the lecturers and demonstrators.

**CHARING CROSS HOSPITAL.**—First year: *a, b*, £4 4s.; *c, g*, £3 3s.; *d*, £5 5s.; *i, l*, £2 2s.; H.P., £10 10s.; Matriculation, £2 2s.—total, £36 15s. Second year: *a, b, c, k, n*, £2 2s.; *e, f, h*, £4 4s.; *j, m*, £3 3s.; H.P., £10 10s.—total, £31 10s. Third year: *e, f*, £2 2s.; H.P., £10 10s.—total, £14 14s. Matriculated students receive a deduction of eight per cent. H.P., matriculated students, for full period required by Examining Boards in London, £31 10s.; non-matriculated students, either medical or surgical, 3 months, £6 6s.; 6 months, £10 10s.; 12 months, £15 15s.; full period, £21; both, medical and surgical, 3 months, £10 10s.; 6 months, £15 15s.; 12 months, £21; full period, £31 10s. For a longer period, £5 5s. for each additional winter, and £3 3 for each additional summer session.

Gentlemen who enter for their entire medical education at Charing Cross Hospital (matriculated students) enjoy certain privileges.—Students who enter from other medical schools for the remainder of their education are allowed to matriculate. Students (non-matriculated) may enter for one or more separate courses, or to the Hospital Practice. Such students are admitted to the Library on terms proportioned to the period for which they enter.

*Scholarships, Medals, and Prizes.*—The Llewellyn Scholarship of £25, open to all matriculated students who have just completed their second year. Examination at the end of the second summer session, in Descriptive and Surgical Anatomy, Physiology, Materia Medica, Medicine, Surgery, Midwifery.—The Golding Scholarship of £15 a year, tenable for two years, open to all matriculated students who have just completed their first year. Examination at the end of the first summer session, in Descriptive Anatomy, Physiology, Materia Medica, and Chemistry.—The following Medals are awarded annually: The Gold Medal, for General Proficiency; the Governor's Clinical Silver Medal; Silver and Bronze Class Medals and Certificates of Honour in all the classes.—Free scholarships are awarded to sons of professional men of

reduced circumstances and position, or of gentlemen in a corresponding station of society. Two of the free scholarships are annually placed at the disposal of the authorities of the Royal Medical Medical Benevolent College.

*Appointments.*—The office of Medical and Surgical Registrar is opened to students of Charing Cross Hospital who are doubly qualified; salary, £50 a year, tenable for two years. The offices of House-Physician, House-Surgeon, and Resident Accoucheur, with six months' rooms and commons in the Hospital, are awarded to senior students (qualified men being preferred), after competitive examination.—Clinical Clerks and Dressers are appointed by competitive examination for three months.—The Physician-Accoucheur has two Clinical Clerks.—A Pathological Assistant is appointed for three months.

The Library contains the standard medical and surgical works and the current medical periodicals, and is furnished with a cabinet of Materia Medica and Osteological Preparations. It is open daily from 9.30 A.M. to 4.30 P.M.

**ST. GEORGE'S HOSPITAL.**—Perpetual Fee, £105,\* or £115 10s. from those who have paid by instalments.—Aggregate Fees, £42 for first year, £42 for second year, and £10 10s. for each succeeding year.† Lectures and Hospital Practice for Diploma in Dental Surgery, £45 (none of these fees include Practical Chemistry).—Separate Classes—*a, b, c, f*, single, £6 6s.; perpetual, £7 7s.; *d*, single, £6 6s.; perpetual, £8 8s.; *g, k*, single, £4 4s.; perpetual, £5 5s.; *h*, single, £5 5s.; perpetual, £6 6s.; *i*, single, £3 3s.; perpetual, £4 4s.; *l*, single, £4 4s.; *n*, single, £5 5s. H.P.—Physicians', 6 months, £8 8s.; 3 years, £16 16s.; perpetual, £25 4s.; Surgeons', 6 months, £15 15s.; 3 years, £21; perpetual, £42.

*Medical Tutor.*—The studies of the pupils will be superintended by a medical tutor. Fee, £1 1s. per annum, and £5 5s. in addition for instruction in the special subjects required for each examination at the University of London.

*Hospital Appointments.*—House-Physicians, House-Surgeons, an Assistant House-Physician, and an Assistant House-Surgeon, half-yearly, from among the perpetual pupils. The House-Physicians and House-Surgeons hold office for twelve months, and reside and board in the hospital free of expense.—An Obstetric Assistant, who must be a legally qualified practitioner, is appointed annually. He resides and boards in the hospital, and receives a yearly salary of £100.—An Ophthalmic Assistant, an Orthopædic Assistant, a Curator of the Pathological Museum, a Medical and a Surgical Registrar, and a paid Demonstrator of Anatomy, are appointed annually from among the senior pupils. The Curators and Registrars each have a salary of £50. One of the pupils is appointed to assist the Curator in performing *post mortem* examinations.

*Clinical Instruction.*—The pupils of the hospital are divided into classes under the superintendence of the physicians and surgeons in rotation, and are placed in charge of cases as clerks and dressers.

The Library and Reading Room, and the Museum, are open daily. Annual subscription to Library, 10s. 6d.

*Exhibitions and Prizes.*—The William Brown Exhibition, for general fitness and moral conduct, £40 per annum, tenable for three years.—Sir Charles Clarke's Prize, interest of £200 annually, for good conduct.—The Thompson Silver Medal for the best clinical report (with observations) of medical and surgical cases (not more than twenty in each department) observed during the preceding year.—Sir Benjamin Brodie's Clinical Prize in Surgery, for the best report (with notes) of not more than twenty surgical cases in the hospital during the preceding twelve months.—Dr. Acland's Clinical Prize in Medicine, for the best record of not more than twelve cases of disease treated in the preceding twelve months.—The Henry Charles Johnson Memorial Prize, for Practical Anatomy.—General Proficiency Prizes, £10 10s. for students of each year.

**GUY'S HOSPITAL.**—First year, £40; second year, £40; each succeeding year, £10. Perpetual ticket, £105. Materials used in practical courses are charged extra. Separate courses: *a, b, c, d, e, f, h, g*, each course, £5 5s.; *g, i, k, l, m, r, s*, each course, £4 4s.; Natural Philosophy, £4 4s.; H.P., either medical or surgical, 3 months, £10 10s.; 6 months, £15 15s.; perpetual, £26 5s.

\* Perpetual Pupils are entitled to admission to the practice of the Physicians and Surgeons, to all the Lectures (except Practical Chemistry), to compete for all Prizes and exhibitions, to hold the appointments of House-Physician, House-Surgeon, and Assistant House-Surgeon, and to become Clinical Clerks for two periods of three months each, and Dressers for two similar periods. This payment must in all cases be made at the time of entry.

† By payment of these Fees, a Pupil is entitled to hold the offices of Clinical Clerk and Dresser, but not to become House-Physician or House-Surgeon, or to compete for the "William Brown Exhibition" and the "Clinical" Prizes.

**Prizes.**—Voluntary examinations are held as follows. 1. At entrance, in Elementary Classics, Ancient and Modern History, and Mathematics. The first three of the successful candidates receive £25, £20, and £15. The entrance examination will commence on October 11th. 2. At end of first year, in Anatomy, Physiology, Chemistry, Materia Medica, and Botany. Three prizes of £30, £25, and £10 10s. 3. At end of second year, in Anatomy and Physiology, Medicine, Surgery, Midwifery, Chemistry, and Therapeutics. Two prizes of £35 and £30. 4. At end of third year, in Medicine and Surgery, Midwifery (theoretical and practical), and Medical Jurisprudence.—Two prizes of £40 and £35. Honorary certificates are given to those gentlemen who pass creditable examinations. Special certificates are given to gentlemen who have attended 100 cases of Midwifery.—Two Gold Medals given annually by the Treasurer to students who have completed the third and not exceeded the fourth year, for proficiency in Clinical Medicine and Clinical Surgery.

**Clinical Instruction.**—Two wards, containing together forty beds, are especially devoted to clinical teaching in Medicine. The Surgeons lecture upon selected cases during the winter, and the Assistant-Surgeons in the summer. The Obstetric Physicians, and the Ophthalmic, Dental, and Aural Surgeons, also give clinical and practical instruction.

Every facility and encouragement is given for clinical study and reporting. All students have opportunities of becoming Ward-Clerks to the Physicians and Surgeons.

Under the superintendence of the Registrars, accurate records are taken and preserved of all cases admitted.

**Pupils' Appointments.**—All these appointments are given according to the respective merits of the candidates, and without payment.

Four House-Physicians are appointed by the Treasurer in each year. They hold office for six months each—three months as junior, three as senior. Six House-Surgeons and two Obstetric Residents every year. Each holds office for four months—two as junior, and two as senior. The Senior House-Physician, House-Surgeon, and Obstetric Resident, reside in the hospital, and are boarded free of expense.—The Clinical Clerks are selected from those students who have been medical ward-clerks.—The Dressers are selected from those who have been surgical ward-clerks. They hold office for six months each. During their weeks of special duty, they reside in the hospital, and board free of expense.—The Dressers in the Eye-Wards hold office for four months each.—The Assistant-Surgeons' Dressers and Dressers in the Surgery are appointed for three months.—Dressers are appointed to the Dental and the Aural Surgeon respectively for two months.—The *Post Mortem* Clerks are selected from students who have completed their second year. They hold office for two months each.—Extern Obstetric Attendants are appointed monthly to attend the cases of Midwifery, in addition to the casual attendants.—The Reporters or Ward Clerks are chosen from those students who have been diligent in their earlier studies.—Clerks to the Assistant-Physicians and Assistant-Surgeons are also appointed.—A special honorary certificate is given to every gentleman who has diligently performed the duties of the various offices.

**School Department.**—There are two Lecture Theatres, Museums of Anatomy, Pathology, and Comparative Anatomy, Model-rooms, Dissecting-rooms, a Museum of Materia Medica, Chemical Laboratories, and a Library.—The Museum of Human Anatomy is divided into anatomical and pathological departments. The anatomical department contains above 2,000 preparations of the various organs and tissues. The pathological department is divided into twelve sections, and contains upwards of 5,000 specimens, with more than 2,000 drawings.—The Museum of Comparative Anatomy contains 2,000 specimens.—In the Physiological Laboratory, experiments are prepared for practically illustrating the lectures on Physiology.—The Museum of Materia Medica contains specimens of the drugs in general use.—A Laboratory is attached.—The Laboratory for Practical Chemistry is open during the summer months.—The Library contains upwards of 5,000 volumes, and is open to the students daily from 9 A.M. to 5 P.M.

The *Pupils' Physical Society* meets on alternate Saturdays, at seven in the evening. A prize of £10 is given from the funds of the Society to the student who reads the best essay on the subject of the month, and a second prize of £5 is given to the member who is judged to have read the best essay before the Society.

**KING'S COLLEGE AND HOSPITAL.**—Aggregate Fee for Matriculated Students, £105.\* The payments may be made by payment of £20 on entrance; or £54 10s. on entrance, £42 at the beginning of the second

cond winter session, and £10 10s. at the beginning of the third winter session. For each additional year, £10 10s.—Separate Classes, *a, b, d*, single, £7 7s.; unlimited, £10 10s.; *c*, single or unlimited, £7 7s.; *f*, single, £6 6s.; perpetual, £7 7s.; *g, h, i, k*, single, £4 4s.; unlimited, £5 5s.; *l*, single, £4 4s.; perpetual, £7 7s.; *m*, single, £3 3s.; unlimited, £4 4s.; *n*, single, £2 2s.; unlimited, £3 3s.; *o*, single, £6 6s.; unlimited, £8 8s.; *p*, single, £3 3s. Tutor's Class, each session, £3 3s. H.P.—Perpetual for Matriculated Students, £31 10s.; non-matriculated, £42. Medical Practice—3 months, £6 6s.; 6 months, £10 10s.; 18 months, £15 15s.; perpetual, £21. Surgical Practice—3 months, £10 10s.; 6 months, £15 15s.; 12 or 21 months, £21; perpetual, £26 5s.

**Clinical Instruction** is given in the wards and by lectures in the medical and surgical departments; also in the Diseases of Women and Children, in Dental Surgery, in Diseases of the Eye, in Throat-Diseases, and in Skin-Diseases.—Demonstrations and practical instruction in Morbid Anatomy are given in the *Post Mortem* Theatre. Students may obtain practical instruction and certificates in Vaccination by the payment of a small fee.—Special instruction is given in Medical Chemistry and the Microscope by the Physicians.

The Museums of Anatomy, Materia Medica, Natural History, etc., are open daily from 10 till 4.

**Resident Medical Officers, Clinical Clerks, and Dressers**, are chosen by examination from matriculated students who are pupils at the hospital.

A permanent record of every case received into the hospital is kept by the Medical and Surgical Registrars.

**Scholarships and Prizes.**—Two Warneford Scholarships, £25 *per annum* for three years, for the encouragement of previous education; and one Warneford Scholarship of £25 *per annum*, for two years, for resident medical students.\*—College scholarships given yearly to matriculated students—one of £40 for two years, open to students of the third and fourth year; one of £30 for one year, open to students of the second year; three for £20 for one year, open to students of the first year.—The Daniell Scholarship, £20 *per annum* for two years.—Sambrooke Registrarships, annual value £50, tenable for two years.—Leathes' Prizes: Interest of £300, applied in purchase of a Bible and Prayer-Book, as annual prizes to two matriculated students.—Warneford Prizes: £40 in medals and books, to two matriculated students.—Class Prizes: Books of the value of £3, and certificates of honour, are awarded annually for proficiency in each of the several subjects taught in the classes.—Two Medical Clinical Prizes, one of £3 for the winter session, and the other of £2 for the summer session; and two Surgical Clinical Prizes of the same value.—Todd Medical Clinical Prize: Bronze Medal and Books to the value of £4 4s.—Jelf Medal, to the candidate of the senior scholarship examination who is second in order of merit.

**Associates of King's College.**—At the end of each winter session, the professors recommend to the Council the names of medical students to be elected associates.

**Residence.**—Rooms are provided within the College for a limited number of matriculated students. The cost of the academical year varies from £50 to £60. Some of the professors, etc., receive pupils into their houses. There is a dining hall in the College.

**LONDON HOSPITAL.**—Aggregate Fee, £90, payable in two instalments of £45 each, at the commencement of the first and second years. Perpetual fee for lectures alone, £50; for both lectures and Hospital Practice, £100, payable in two instalments of £50 each, or two of £45 each, and one of £10 10s. Composition fee for gentlemen who have spent their first year elsewhere, £70, payable in two equal instalments. Students who have paid the general aggregate fee can become perpetual

\* Two Scholarships, of the value of £25 *per annum* each, to be held for three years, will be given in October 1871. Candidates must be matriculated students of the Medical Department, and also perpetual pupils of the hospital. Their first winter session must commence in October 1871. The examination will be in the following subjects: 1. Divinity: Old Testament History; The Acts of the Apostles in Greek; The Church Catechism, with explanations. 2. The Greek and Latin Classics: Homer, *Iliad*, book ix.; Cicero, *Oratio II. in Catilinam*. 3. English Language and History: Shakespeare, *Julius Caesar*; History of England to the end of the Seventeenth Century. 4. Mathematics: Arithmetic; Algebra, as far as and including Quadratic Equations; Euclid, book i.; book ii., except propositions 8, 9, 10, 11, 12, 13. 5. Modern Languages: French, Camille, *Horace*; German, Schiller, *Wilhelm Tell*. For further particulars, see the King's College Calendar. The day of Examination are September 23, 24, 25, and 26. One Scholarship will be awarded at the close of July, 1872, of the value of £25 *per annum*, to be held for two years. The Examination for 1872 will be in the Book of Psalms, the Acts of the Apostles, the Epistles to the Thessalonians, Westcott's *Bible in the Church*. Candidates will be required, at the time of examination: 1. To write from memory the particulars of four cases treated in the Hospital during the previous academical year. 2. To give, in writing, with the aid of notes taken by himself at the time, the substance of four Clinical Lectures delivered in the Hospital during the previous year. The Lectures to be selected by the Examiners. 3. To answer, either  *viva voce* or in writing, four questions on cases in the Hospital in the current session.

\* Students on entrance pay £10 and £4 10s. for a quarter course of Chemistry, and £11 10s. for the Medical Terms' fee. Attendance on the Medical List is compulsory on matriculated students during their first year.

at any time by paying the additional £10 10s. Extra fees: Library, £1 1s.; Practical Pharmacy, £4 4s. Separate classes: *a*, *h*, one session, £4 4s.; unlimited, £6 6s.; *b*, *c*, one session, £5 5s.; unlimited, £8 8s.; *d*, one session or unlimited, £7 7s.; *e*, *f*, one session, £5 5s.; unlimited, £6 6s.; *g*, *i*, *k*, *m*, *r*, one session, £3 3s.; unlimited, £4 4s.; *l*, one course to students of schools, £2 2s.; to others, £3 3s.; *n*, one year, £3 3s.; perpetual, £6 6s.; *o*, one course, £2 2s.; Diseases of Throat, and Diseases of Eye, each, one course, £2 2s.; unlimited, £3 3s.—H.P.—Medical: 6 months, £6 6s.; period required by Apothecaries' Hall, £12 12s.; unlimited, £21. Surgical: 6 months, including 3 months' dressership, £8 8s.; 12 months, including 6 months' dressership, £12 12s.; 18 months, including 12 months' dressership, £18 18s.; 3 years, including 12 months' dressership, £26 5s.; 3 years, including 2 years' dressership, £3 10s.; 12 months' dressership after the expiration of the above 3 years, £8 8s.

The Anatomical and Pathological Museum, the Materia Medica Museum, and the Library, are open daily.

**Scholarships and Prizes.**—Seven scholarships will be offered for competition. 1 and 2. Two Buxton Scholarships, value £30 and £20, will be given in October, after examination in the subjects of preliminary education.\* These scholarships are open to full students of less than three months' standing. 3. A scholarship in December 1871, value £20, to a first year's student: subject, Human Anatomy. 4. A scholarship, value £25, to a first or second year's student, at the end of the winter session: subjects, Anatomy, Physiology, and Chemistry. 5, 6, 7. Hospital Scholarships, value each £20, for proficiency and zeal in Clinical Medicine, Surgery, and Obstetrics.—The Duckworth Nelson Prize, value £10, at the end of the winter session, 1873, open to all students who have not completed their education: subjects, Practical Medicine and Surgery.—Money prizes to the value of £60 *per annum* to the most meritorious of the dressers in the out-patient rooms.—Special certificates to those gentlemen who have faithfully performed their duties in the hospital, and to those who have distinguished themselves at the examinations.

**Appointments.**—A Resident Medical Officer, qualified to practise Medicine, who receives £75, is appointed for twelve months. He is eligible for re-election, and then receives £100. A Junior Resident Medical Officer is appointed every six months. Four Medical Assistants, one for each Physician, are appointed every three months. Every student is expected to act as Clinical Clerk. A Resident Accoucheur is appointed for six months.—Four House-Surgeons are elected, usually for six months.—Any student may enter his name on the list as a Dresser. Two Dressers reside and board in the hospital every week.—Two Clinical Assistants are appointed every three months for the medical and two for the surgical out-patients and patients in the special departments. They are eligible for re-election. Each receives £40 *per annum*.—A Medical Registrar and a Surgical Registrar are appointed annually; the former receives 25, the latter 35, guineas.—An Assistant-Dentist, *Post Mortem* Clerks, and two Prosectors of Anatomy, are also appointed.—Full pupils, and those who, having commenced elsewhere, pay the general fee to the hospital and college, are eligible for all scholarships, prizes, and appointments.—Students who have commenced elsewhere, but who, at or before the beginning of the second winter session, become pupils of the hospital and college by paying the composition fee, will be eligible for the Dresserships, for three months as House-Surgeon, and for the offices of Ward-Clerk, *Post Mortem* Clerk, Maternity Pupil, Clinical Assistant, and Registrar.

All the appointments are open to students without fee. The holders of all resident appointments are provided with rooms and board free of expense.

**Clinical Instruction.**—Two medical wards, containing together thirty beds, have been set apart for clinical teaching. The Clinical Professor will meet his class twice a week. Bedside instruction will also be given by the physicians not on special clinical duty. Students requiring signatures for medical practice must attend the Clinical Professor.—Dr. Davies will hold in the summer a class for Practical Auscultation and Percussion.—In the out-patient department, the Physicians and Assistant-Physicians impart instruction each visit.—The Surgeons make clinical observations on their cases, and a clinical lecture is given once a week.

**Special Departments.**—There are departments for instruction in Obstetric Medicine and Surgery, Vaccination, Diseases of the Eye and the

Use of the Ophthalmoscope, Diseases of the Ear, Diseases of the Skin and of the Throat, Syphilis and Local Contagious Diseases, and Mental Diseases. Students desirous of obtaining a practical knowledge of Mental Diseases can attend, without additional fee, the practice of Dr. Millar at the Bethnal House Asylum.

**ST. MARY'S HOSPITAL.**—Aggregate Fee, £89 5s. in instalments, or £84 in one sum.—Fee for all lectures required for ordinary examinations, £52 10s.; for hospital practice, £36 15s.; for lectures and hospital practice, £89 5s.—Unlimited attendance on hospital practice and all lectures, £105 in instalments, or £99 15s. in one sum.—Separate classes, *a*, *i*, *k*, *r*, one course, £3 3s.; unlimited, £4 4s.; *b*, one course, £6 6s.; unlimited, £8 8s.; *c*, £1 15s. first and second sessions; *d*, one course, £5 5s.; unlimited, £7 7s.; *e*, *f*, *g*, *h*, one course, £4 4s.; perpetual, £6 6s.; *l*, one course, £3 3s.; *m*, one course, £2 2s.; unlimited, £3 3s.; *n*, *o*, *p*, and Aural Surgery, one course, £2 2s.—H.P.—Medical: 3 months, £5 5s.; 6 months, £7 7s.; 12 months, £12 12s.; 18 months, £15 15s.; unlimited, £21. Surgical: 3 months, £6 6s.; 6 months, £9 9s.; 12 months, or time required by College of Surgeons, £21; unlimited, £31. Practical Pharmacy: 3 months, £3 3s.; 6 months, £6 6s.; 12 months, £10 10s.—Vaccination, £1 1s.—Library fee, £1 1s.

**Special Courses** are given on Ophthalmic, Aural, and Dental Surgery; also clinical demonstrations on Diseases of the Skin and of the Throat.

**Hospital Appointments** are open to the pupils without additional fee. Three Resident Medical Officers are appointed for twelve months, and an Obstetric Officer for six months; all live free of expense in the hospital.—A Resident Registrar is appointed, with a salary of £100 a year; he holds office for two years, and may be re-elected.—All general students must act as clinical clerks and dressers for six months during the last two years.

**Clinical Lectures** twice a week by the Physicians and Surgeons. The students are divided into three classes, each committed to the charge of a Physician and Surgeon for a definite period. The attendance of the students is noted at each visit.

**Scholarships and Prizes.**—A Scholarship in Natural Science, value £40, for three years, to be awarded at the beginning of the winter session; and an Exhibition of £20 for one year to the second candidate in order of merit.—A prize of £4 4s. in Anatomy and Physiology, and three of £2 2s. each in Chemistry, Practical Chemistry, and Materia Medica and Botany, to first year's students.—A Scholarship in Anatomy, value £20, for one year; and a prize of £2 2s. for Midwifery; to students of the second year.—Prizes of £3 3s. each in Medicine and in Surgery, and one of £2 2s. in Comparative Anatomy, for third year's students.—A prize of £4 4s. for Clinical Medicine and Clinical Surgery to students of the third and fourth years.—Scholarships in Pathological Anatomy, value £20, tenable for one year, to students who have completed the third winter session.—Two Prosectors are appointed annually, who each receive a certificate and £5.

The **Reading Room and Library** is open daily. A fee of £1 1s. (perpetual) is paid on entrance by each student.—The **Museum** is open daily to students.

**MIDDLESEX HOSPITAL.**—Aggregate Fee, £90 in one sum; or in instalments of £35 at the beginning of the first and second sessions; £20 at the beginning of the third session; and £10 for each additional year, or separate fees for the hospital practice or lectures attended.—Aggregate Fee for hospital practice alone, £42.—Separate Classes—*a*, *c*, *d*, *e*, *f*, single, £6 6s.; unlimited, £8 8s.; *b*, single, £8 8s.; unlimited, £12 12s.; *g*, *h*, *i*, *k*, single, £4 4s.; unlimited, £5 5s.; *l*, *m*, single, £3 3s.; *n*, single, £3 3s.; unlimited, £4 4s.; *q*, single, £6 6s.; *r*, single, £4 4s.—H.P.—Unlimited, £26 5s.; or in instalments of £10 10s. each at commencement of first and second years, and £5 5s. for each subsequent year. Medical or surgical practice separately, one year, £8 8s.; three months, both, £7 7s.; either, £5 5s. Registration fee (occasional students), £1 6s.; Vaccination, £1 1s.; Dental practice (occasional students), £5 5s.; Pharmacy, without dispensing, 3 months, £4 4s.; with dispensing, 6 months, £5 5s.; 12 months, £8 8s.

**Appointments, etc.**—Two House-Surgeons are appointed annually. Candidates must be 21 years of age, and must have obtained certificates of proficiency as in-patient dressers. The Junior House-Surgeon succeeds to the office of Senior House-Surgeon only if he have performed his duties satisfactorily. Each House-Surgeon pays a fee of £21; if he have not been a surgical pupil of the hospital, he pays £31 10s. Three Resident Physicians' Assistants are appointed annually. They must have a legal qualification. Each Resident Physician's Assistant

\* The subjects of examination will be:—1. The English Language, including Grammar and Composition. 2. Arithmetic, including Vulgar and Decimal Fractions. 3. Algebra, including Simple Equations. 4. Geometry—first Two Books of Euclid. 5. Latin—Caesar, *De Bello Gallico*, Book II. 6. One of the following subjects at the discretion of the Candidate: *a*) Greek—Xenophon's *Anabasis*, Book I.; *b*) French—X. B. Saintime's *Picciola*; *c*) German—Schiller's *Wilhelm Tell*; *d*) Natural Philosophy—Mechanics, Hydrostatics, Pneumatics.

\* The aggregate fee admits to the Library, to one course of Practical Chemistry and two courses of Dissections, to all the lectures, and to the instruction of the tutor: it includes also all charges for Clinical Clerkships and Dresserships.

pays £10 10s. on appointment; he must either be a medical pupil of the hospital, or pay half the fee for twelve months' medical practice. A Resident Obstetric Assistant is appointed for six months. He pays £10 10s. Clinical Clerks and Dressers are appointed for six months. The appointments are so arranged that every student may take both a clerkship and a dressership at some period. Each student must be an out-patient clerk and out-patient dresser for six months respectively before being eligible to an in-patient clerkship or dressership.

The College Tutor assists all general students of the hospital, especially those who are preparing for examination.

Clinical Lectures are delivered regularly by the Physicians and Surgeons, and by the Physician-Accoucheur and the Ophthalmic Surgeon. Special instruction in Diseases of the Skin are given during the summer session.

Prizes.—Three chief prizes for competency in Clinical knowledge are annually awarded after competitive examination; viz.: the Governors' Prize, value £21, and two Prizes of £6 6s. and £4 4s. These are open to competition amongst students who have completed their second, and not exceeded their third, winter session.—Written periodical class examinations are held, and must be attended by all general students.—Class Prizes are given in each subject.—A Prize is also given for the best Dissection during the winter session.

The Museum is open to students daily from 9 to 5. It contains above 5000 specimens.—Admission to the Library and Reading Room is included in the fee paid by general students. Occasional students may use the Library on payment of £1 1s.

ST. THOMAS'S HOSPITAL.—Aggregate fee (giving unlimited admission), £105 in one sum; or £40 each for the first and second years; £20 for the third; and £10 for each succeeding year. Special entries may be made to any course of lectures or to the hospital practice.

Prizes.—The William Tite Scholarship, consisting of the interest of £1000 consols, awarded every third year and tenable for three years; and College Prizes for each year's students, of £20, £15, and £10 each winter, and £15, £10, and £5 each summer.—The Cheselden Medal, annually, for Surgery and Surgical Anatomy.—The Treasurer's Gold Medal, annually, for general proficiency and good conduct.—The Grainger Testimonial Prize, value £20, biennially, to third or fourth year's students, for a Physiological Essay.

Appointments.—Clinical Clerks and Dressers, and Obstetric Clerks, are selected according to merit; the Dressers and Obstetric Clerks are provided with rooms and commons free of expense. The House-Surgeons and Resident-Accoucheur are selected according to merit from gentlemen who have obtained their diplomas: the former hold office for six or twelve months; the latter for three or six. All are provided with rooms and commons.—A Medical and a Surgical Registrar are appointed from among gentlemen who have completed their studies in the school. Each Registrar, on completing his Annual Report to the satisfaction of the physicians or surgeons, receives £40. One Registrar, with a salary of £80, may be appointed.—Students have access to the Library and to the Museums of Anatomy and Pathology, and of Materia Medica and Pharmacy.—Laboratories under the direction of the Physiological and Chemical Lecturers are provided.—There are special departments, for Diseases of Women and Children, Diseases of the Eye, Skin, and Teeth, and for Vaccination.—A limited number of students can reside with some of the officers of the hospital.

UNIVERSITY COLLEGE AND HOSPITAL.—Aggregate Fees £104 : 14; or first winter session, £36 5s.; first summer session, £11 11s.; second winter session, £31; second summer session, £7 7s.; third winter session, £11 4s.; third summer session, £7 7s. Separate Classes: a, session, £7 7s.; first half session, £4 4s.; second, £3 3s.; perpetual, £9 9s.; b, *with c*, entire session, £7 7s.; half session, £4 4s.; perpetual, to Lecturers, with three years' Practical Anatomy, £10 10s.; Practical Anatomy after the third year, every winter session, £1 1s.; Practical Anatomy without Lectures for three summer months, £2 2s.; d, e, whole course, £9 9s.; half course, £3 3s.; perpetual, £9 9s.; f, session, £5 5s.; half session, £3 3s.; perpetual, £6 6s.; g, h, n, single, £4 4s.; perpetual, £6 6s.; i, e, single, £3 3s.; perpetual, £4 4s.; l, elementary and senior courses, single (each), £4 4s.; perpetual (each), £7 7s.; summer matriculation course, £4 4s.; m, comparative Anatomy, £4 4s.; Zoology, £4 4s.; perpetual to both, £9 9s.; o, p, single, £2 2s.; p, single, £4 4s.; r, session, £6 6s.; perpetual, £9 9s.; Pathology, single, £1 1s.; Mental Diseases, £2 2s.; Organic Chemistry, £2 2s.; Use of Surgical Apparatus, single, £1 1s.; 6d.; perpetual, £2 2s.; Hygiene and Public Health, single, £1 1s.; Physiological Laboratory, first month, £2 2s.; each succeeding month, £1 1s.—H.P.—Perpetual, £27; one year, £10; six months, £7. Practical

Pharmacy, six months, £5 5s.; three months, £3 3s.—Students may attend the practice of the Middlesex Hospital on paying a sum which, with their previous payments for hospital practice, will make up £30.

Scholarships, etc.—Three Entrance Exhibitions, value £30, £20, and £10 per annum, tenable for two years, to gentlemen who are about to commence their first winter's attendance.\*—The Atkinson-Morley Surgical Scholarship, £45, tenable for three years, for proficiency in Surgery.—The Sharpey Physiological Scholarship, present value about £95.—The Filliter Exhibition of £30, annually in July, for Pathological Anatomy.—Dr. Fellowes's Clinical Medals, one Gold and one Silver, with Certificates of Honour, at the end of each session.—The Liston Gold Medal, with Certificates of Honour, at the end of the session, for reports and observations on the Surgical Cases in the Hospital.—The Alexander Bruce Gold Medal, for proficiency in Pathology and Surgery.—The Cluff Memorial Prize, every second year, for Anatomy, Physiology, and Chemistry.—Gold and Silver Medals, or other Prizes, as well as Certificates of Honour, after competitive examinations in the classes. Prizes to the value of £10 in the class of Hygiene.

Libraries and Museums.—The General Library, the Medical Library, the Museums of Anatomy and Pathology, of Comparative Anatomy, of Materia Medica and Chemistry, of Geology, and of Natural Philosophy, are open daily. There are also a Chemical and a Physiological Laboratory.

Clinical Instruction is given by the physicians and surgeons in the wards and in the out-patient department, and by lectures and examinations. Dr. Wilson Fox, the Holme Professor of Clinical Medicine, delivers Clinical Lectures, and trains the Pupils in the practical study of disease. Lectures are given twice a week by Mr. Erichsen, the Holme Professor of Clinical Surgery; once a fortnight or oftener by Mr. Marshall and Sir Henry Thompson. Clinical Lectures on Midwifery and the Diseases of Women are delivered once a fortnight; also on Ophthalmic Surgery and on Diseases of the Skin. Arrangements are made for practical instruction in Vaccination.

Private Instruction.—Gentlemen may obtain assistance in their studies within the College, on application to the respective Professors.

Residence of Students.—Several gentlemen connected with the College receive students to reside with them; and in the office of the college there is kept a register of persons who receive boarders.

Officers.—Physicians' Assistants, House-Surgeons, Midwifery Assistants, Physicians' Clerks, Surgeons' Dressers, Ophthalmic Surgeons' Assistants and Ward-Clerks are selected from among the pupils without additional fees. The Physicians' Assistants, the Obstetric Assistant, and the House-Surgeons reside in the Hospital, paying for their board. Six Dresserships at the Royal Free Hospital have been placed at the disposal of the College.

WESTMINSTER HOSPITAL.—Aggregate Fee, £70; or in instalments of £35 at the commencement of the first year, £30 at the commencement of the second year, and £10 at the commencement of the third year.—Perpetual Fee to all Lectures and Hospital Practice, £75 on entry, or in instalments of £40 each at the commencement of the first and second years.—Lectures and Hospital Practice for any single year, £35.—Separate Classes:—a, b, d, e, f, single, £5; perpetual, £7; c, single, £2; perpetual, £3; g, i, k, single, £3; perpetual, £4; h, single, £4; perpetual, £5; l, m, single, £2; Natural Philosophy, single, £1.—Vaccination, £1 1s.—Practical Pharmacy, 3 months, £5; six months, £8.—H.P.—Period required by Colleges and Society of Apothecaries, £26; perpetual, £30. Medical or Surgical separately, each, six months, £8; twelve months, £12; eighteen months, £15; perpetual, £20. Students can attend, without additional fee, the practice of the Royal Westminster Ophthalmic Hospital and of the National Hospital for Paralysis.

There are separate departments for Diseases of the Eye and of the Skin, and for Diseases of Women.

The Anatomical Museum is constantly open to the student. There are also a Pathological Museum and a Materia Medica Museum.—The Reading Room is open daily.

Arrangements have been made for the residence of students.

Appointments.—House-Physicians and House-Surgeons are appointed by competition, without fee, and are provided with board and lodging free of expense.—An Assistant House-Surgeon is appointed without fee from among the senior students. He is provided with commons at the

\* The subjects of examination are the following. Latin and Greek.—Translation into English of passages from Cæsar and Xenophon; Translation of short English sentences into Latin.—French or German.—Translation into English of passages from Bonnet's *Discours sur l'Histoire Universelle*, or of passages from Scheller's *Geschichte des deutschen Volkes*.—Mathematics and Natural Philosophy.—the subject required for the Matriculation Examination of the University of London, with the addition of Acoustics, Nature of Sound.—The next examination will take place on September 20th and 21st, 1871.

hospital table.—Clinical Clerks and Dressers are appointed without fee, in rotation.—A Resident Obstetric Assistant is appointed.

*Prizes.*—A Prize of Books or Instruments and Certificates of Honour in each class.—Prizes each £5 5s., first and second year's students, for General Proficiency.—Scholarship in Anatomy and Physiology, value £21, to student of second year (to be styled Assistant Demonstrator). After the second year, prizes of £5 5s. each for Clinical Medicine and Clinical Surgery.—Chadwick Prize for General Proficiency, £21, to the most meritorious student or students of any year not exceeding the fifth.

## NOTES CONCERNING THE PROVINCIAL AND SCOTCH HOSPITALS AND MEDICAL SCHOOLS.

**BIRMINGHAM.—QUEEN'S COLLEGE.**—Aggregate Fee for all lectures required, £52 10s., payable in two equal instalments at entrance and at commencement of second year.—Separate Classes: *a, b, c, f*, single, £5 5s.; perpetual, £8 8s.; *c, d, h*, single, £4 4s.; perpetual, £6 6s.; *g, i, k, l*, single, £3 3s.; perpetual, £5 5s.; *m, o, p*, single, £3 3s.; two courses, £5 5s.—Rooms and board, £50 *per annum*, payable in three instalments.—H.P.—*General Hospital*: Medical and Surgical Practice, 6 months, £10 10s.; a year, £15 15s.; perpetual, £31 10s.—*Queen's Hospital*: Fees the same as at the General Hospital; with £2 2s. for department of Midwifery and Diseases of Women.

*Clinical Instruction.*—Clinical Lectures and lectures in special departments are given at both Hospitals. At the Queen's Hospital, there are wards for Diseases of Children and Venereal Diseases.

*Appointments.*—*General Hospital*: Resident Medical Assistant, and Resident Surgical Assistant, each for 12 months; two Resident Dresserships, tenable 6 months: all after examination, and with board and lodging. *Queen's Hospital*: Resident Physician's Assistant and Resident Surgeon's Assistant, every six months after examination; board and lodging. No fee for clerkships or dresserships.

The Museums of Anatomy and Pathology, and the Library, are open to the students.

*Prizes.*—Two Warneford Scholarships, annually after examination.—The Sands Cox Prize, value £20, annually, to students who have completed their curriculum, after examination in Medicine, Surgery, and Midwifery.—Warden's Prize, £5 5s., to the most proficient student of the first year.—The Percy Prize, books of the value of £5 5s., for the best examination in German.—Silver Medals and Certificates of Honour, annually, in each class after examination.

*Clinical Prizes.*—*General Hospital*: Surgery, first year, two prizes of £3 3s. and £2 2s.; Surgery, second and third years, and Medicine, second and third years, one prize of £5 5s. in each subject, each year.—*Queen's Hospital*: second year, two prizes of £3 3s. and £2 2s. in Medicine, and the same in Surgery; third and fourth years, two prizes of £5 5s. and £3 3s. in Medicine, and the same in Surgery.

**BRISTOL MEDICAL SCHOOL.**—Perpetual Fees to Lectures (except Comparative Anatomy), £57 15s. Separate Classes: *a, b, c, f*, single, £5 5s.; perpetual, £8 8s.; *d*, single, £5 5s.; perpetual, £7 7s.; *g, h*, single, £4 4s.; perpetual, £6 6s.; *i, k, l*, single, £3 3s.; perpetual, £5 5s.; *m*, single, £4 4s.; *n*, single, £3 3s.; perpetual, £4 4s.—H.P.—*Royal Infirmary*. Surgeon's pupil, 1 year, £12 12s.; 2 years, £21; 3 years, £26 5s. Dresser (extra fee), 1 year, £12 12s.; 2 years, £21; 3 years, £26 5s. Physician's pupil, 6 months, £8; 1 year, £15; 18 months, £20; perpetual, £25. Entrance Fee, £5. Library, £1 *per annum*. Apprenticeship to House-Surgeon, including five years' residence, and attendance on Hospital Practice, £315.—*General Hospital*. Medical or Surgical Practice, 6 months, £6; 1 year, £10; perpetual, £20. Extra Fee for Clinical Clerk or Dresser, £5 5s. for six months. Library Fee, £1 1s. *per annum*. Resident pupils, £100 for the first year; £60 for each subsequent year; or 5 years, with apprenticeship, £260.

*Clinical Instruction, etc.*—Clinical Lectures are delivered at the Royal Infirmary and the General Hospital.

The Royal Infirmary and the General Hospital each contain a Library and a Museum.

*Prizes.*—Prizes and Certificates of Honour will be distributed at the end of the winter session, after examination in all the subjects of each year.—Prize and Certificates of Honour for Practical Anatomy.—*Royal Infirmary*. Supple's Medical Prize, and Supple's Surgical Prize; each a gold medal value £5 5s., and about £7 7s. in money. Clark's prize (interest of £500) to the prizeman of the third year in the medical school, if he have attended the Royal Infirmary.—*General Hospital*. Guthrie Medical Scholarship and Clarke Surgical Scholarship, each £15, annu-

ally. Sanders Scholarship (interest of £500) for proficiency in Medicine and Surgery.

**LEEDS SCHOOL OF MEDICINE.**—Aggregate Fee for Lectures required by examining bodies, £46 4s. Entrance Fee to Library and Reading-room, £1 1s. Separate Classes: *a* (including practical course), 1st session, £5 5s.; 2nd session, £5 5s.; *d, f*, 1st session, £4 4s.; 2nd session, £3 3s.; *b*, 1st session, £6 6s.; 2nd session, £5 5s.; *c*, 1st session, £5 5s.; 2nd session, £3 3s.; *g, h*, 1st session, £4 4s.; 2nd session, £2 2s.; *i, k*, 1st session, £3 3s.; 2nd session, £1 1s. 6d.; *l*, each course, £3 3s.; *m*, each course, £2 2s.—H.P.—Leeds Infirmary, Medical or Surgical, each—a winter session, £7 7s.; a summer session, £6 6s.; 12 months, £12 12s.; 18 months, £15 15s.; 3 years, £21.

Clinical Lectures are delivered by the physicians and surgeons of the Infirmary.—A special course of Practical Surgery is given.—Demonstrations of Skin Diseases, Ophthalmoscopic Demonstrations, and Demonstrations of Aural Diseases, are given.—Instruction in the Use of the Microscope is given weekly.—The West Riding Lunatic Asylum at Wakefield is open for the study of Mental Diseases, and a course of lectures will be given during the summer.—Students can also attend the practice of the Leeds Public Dispensary, and the Fever Hospital.—There are several Resident Appointments at these Institutions. The school buildings comprise Lecture-Rooms; Anatomical, Physiological, Pathological, Chemical, Botanical, and Materia Medica Museums; Laboratories; Dissecting Rooms; Library, etc. There is a large and well-fitted Chemical Laboratory, where instruction in Practical Chemistry is given. The fees are: 1 month, £4 4s.; 2 months, £7 7s.; 3 months, £10 10s.; 4 months, £13 13s.; 5 months, £15 15s.; 6 months, £17 17s.; 9 months, £21.

*Hospital Appointments.*—Every student in turn must pass through the offices of Clinical Clerk and Dresser. Four House-Surgeons are elected from among the senior students who have shown industry and skill as Dressers and Clinical Clerks.

*Prizes.*—At the close of each session, Silver and Bronze Medals, Books, and Certificates of Honour, are presented according to merit.—The Hardwicke Clinical Prize, value £10, is given annually for the best reports of medical cases, and the Surgeons' Clinical Prize of £10, for the best reports of surgical cases, during the winter session.—The Thorp Scholarship in Forensic Medicine (£10) at the close of each summer session.—Two Chemical Scholarships are offered annually for proficiency in Chemistry.

**LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.**—Aggregate fee for lectures, £47 5s., or in two equal instalments. Separate classes (each course), *a, b, c, f, g, h*, £4 4s.; *c, i, k, l, n*, £3 3s.; *d*, £5 5s.; *m, o, p*, £2 2s. Vaccination, £1 1s. Practical Pharmacy, £2 2s. Dental Mechanics, £2 2s.—H.P.—*Royal Infirmary*, Medical or Surgical, each—6 months, £5 5s.; 12 months, £6 6s.; perpetual to both, £31 10s. Lock Hospital attached to the Infirmary: 6 months, £2 2s.; 12 months, £3 3s.—*Northern Hospital*: perpetual, £31 10s.; a year, £12 12s.; 6 months, £9 9s.; 3 months, £6 6s. For either the medical or the surgical practice separately, half the above fees.

*Appointments: Royal Infirmary.*—Six Dressers and Six Clinical Clerks are elected annually. Two *Post Mortem* Clerks are appointed for six months. Four Apprentices are admitted to reside and Board in the Infirmary.

Clinical lectures are given weekly at the Infirmary.

There are a Museum containing specimens of Morbid and Comparative Anatomy; a collection of Wax Models and a collection of Materia Medica; Library; and a Reading Room.

*Exhibitions and Prizes.*—Royal Infirmary Medical Scholarship, value £42, consisting of a Gold Medal, value £10 10s., and six months' free board and residence, with dressership and clerkship in the Royal Infirmary.—Four Exhibitions, value £31 10s. each, consisting of free board and residence in the Royal Infirmary for six months, with dressership.—Medals and Certificates of Honour in the various classes.—Clinical Prize in May 1872, £5 for the best report of twelve surgical cases in the Infirmary.

**MANCHESTER ROYAL SCHOOL OF MEDICINE.**—Aggregate fee for lectures, £42. Separate classes for one course, *a, b, d, c, f, g, h, k, l, n*, £4 4s.; *c, i, k, l, p*, £2 2s. [In Practical Chemistry there is an additional charge of 10s. 6d. for chemicals.]—H.P., Royal Infirmary, composition fee, £42, or two instalments of £22 each; or Medical Practice, £18 18s.; Surgical, £31 10s.—Practical Pharmacy, 3 months, £3 3s.; 6 months, £5 5s.

Connected with the School are Museums of Human and Comparative Anatomy and of Materia Medica, and a Chemical Laboratory.

*Appointments.*—Each student is required to fill the offices of Dresser

For further particulars regarding each Hospital and Medical School, see pp. 305 and 308.

(b) *Physicians*, Dr. Heaton, Dr. Clifford Allbutt, Dr. Edlison. *Surgeons*, Mr. S. Hey, Mr. Wheelhouse, Mr. T. P. White, Mr. T. K. Jessop. *Surgeons to the Eye and Ear Department*, Mr. J. A. Sannely, Mr. J. A. Seaton, Dr. K. T. Land. *Surgeons to the Skin and Venereal Diseases*, Mr. J. A. Sannely, Mr. J. A. Seaton, Dr. K. T. Land. *Physicians*, Dr. Vose, W. S., 12, 15; Dr. Turnbull, M. Th., 12, 15; Dr. Waters, Tu. F., I. *Surgeons*, Mr. Stubbs, Tu. 1, 2, 50, F., 1; Mr. Bickerseth, M. Tu. Th., I; Mr. Hakes, Tu. W. S., I. *Assistant-Surgeons*, Mr. R. Harrison, 1, 2, 50, F., 1; Mr. Harrison, Mr. Suapp. *Pathologists*, Tu. I. *Surgeons*, Tu. I. *Physicians*, Dr. Eason Wilkinson, Dr. Smith, Dr. Browne, Dr. W. Roberts, Dr. H. Simpson, Dr. J. E. Morgan. *Surgeons*, Mr. Beever, Mr. W. Smith, Mr. Southam, Mr. F. A. Heath, Mr. Lud. Mr. Rowing. *Physicians*, Dr. de Bartolome, Dr. Law, Dr. Frank-Smith. *Surgeons*, Mr. Barber, Mr. W. F. F. F. Velli, Mr. Parker. *Physicians*, Dr. Charlton, Dr. Embleton, Dr. Philipson. *Surgeons*, Dr. Heath, Mr. Russell, Dr. Arnison, Mr. L. Armstrong. *Assistant-Surgeons*, Mr. A. Bell, Dr. H. M. J. Hawthorn, Mr. C. Jeaffreson.

# TABLE OF THE MEDICAL OFFICERS, PROFESSORS, AND LECTURERS IN MEDICAL SCHOOLS OF SCOTLAND.

For further particulars regarding each Hospital and Medical School, see p. 308. The letters (W.) and (S.) in this Table denote respectively Winter and Summer Courses.

<sup>o</sup>. GLASGOW ROYAL INFIRMARY: *Physicians*—Dr. Gairdner, Dr. Steven, Dr. Perry, Dr. McCall Anderson, and Dr. Scott Orr; *Surgeons*—Dr. E. Watson, Dr. Dewar, Dr. Macleod, Dr. G. Buchanan, and Dr. Morton.

<sup>p</sup>. Ophthalmic Medicine and Surgery, Dr. J. R. Wolfe.

<sup>q</sup>. Surgical Anatomy, Dr. Buchanan, 12 (S.) Osteology for Beginners, Dr. Buchanan (S.)

and Clinical Clerk in the Royal Infirmary. Two House-Surgeons and four Physicians' Assistants are appointed annually, with board, residence, and salary.

**Prizes.**—In addition to three scholarships, value £20, £15, and £10, for perpetual students, prizes for General Proficiency, and Certificates of Honour for regularity of attendance and general good conduct, will be given at the end of each session.—Medical and Surgical Clinical Prizes, value of each £6 6s., are given for reports of cases.

**SHEFFIELD MEDICAL SCHOOL.**—Aggregate fee for lectures, £40. Separate classes: *a* and *b*, first course, £6 6s.; second course, £4 4s.; *d*, each course, £4 4s.; *e*, *f*, first course, £4 4s.; second course, £2 2s.; *g*, *h*, *i*, *k*, *l*, each course, £3 3s.—H.P., Sheffield General Infirmary, Medical or Surgical, 6 months, £6 6s.; 12 months, £10 10s.; Perpetual—Medical, £15 15s.; Surgical, £21.

Further opportunities for practice may be obtained at the Sheffield Public Hospital and Dispensary, and at the Sheffield Hospital for Diseases of Women.

The Infirmary contains a Museum of Pathology, a Library, and a *Post Mortem* Theatre, with Microscopes and all the appliances for clinical research.—The Library of the Medical School is open to students.

**UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.**—Fee for all the lectures (except Practical Pharmacy): one payment, £46 4s.; two payments, each £25 4s.; three payments, each £18 11s. Single courses, £4 4s. each. Vaccination, £1 1s.—H.P., Newcastle Infirmary: 3 months, £4 4s.; 6 months, £5 5s.; 12 months, £7 7s. Perpetual fee, £17 17s.; or by instalments, first year, £7 7s.; second year, £6 6s.; third year, £5 5s.

Two Resident Clerks, and four Resident Dressers and four Non-resident Dressers, are elected half-yearly. They are provided with board and apartments free.

Midwifery can be attended at the Newcastle Lying-in Hospital, and Diseases of the Eye at the Eye Infirmary.—Lectures on Psychological Medicine will be given at the Dunston Lodge Asylum.—The Chemical Laboratories are open daily throughout the year, from 10 to 5 o'clock. Students can attend laboratory practice and receive instruction in analysis for—6 days weekly, £31 10s. *per annum*; 4 days, £21 *per annum*; shorter periods, by arrangement.—The Libraries and Museums are open daily.

**Pharmacy.**—Special arrangements have been made for instruction in Pharmacy. The curriculum will consist of courses of lectures in Botany, *Materia Medica*, Chemistry, and Pharmacy. Fee for curriculum, perpetual, £6 6s.; separate courses, each £4 4s.

**Prizes.**—A *Medical Scholarship*, annual value £25, for four years, in October 1871, to students who have been registered at Durham.—The Dickinson Memorial Scholarship, value £15 annually, after the first examination of a licensing board.—A Silver Medal and Certificates of Honour in each class.

**UNIVERSITY OF ABERDEEN.**—The fee to each class in the Faculty of Medicine is £3 3s., except Practical Anatomy and Demonstrations, for which the fee in each session is £2 2s. Matriculation fee, both sessions, £1; summer session alone, 10s.

**ROYAL INFIRMARY, ABERDEEN.**—Perpetual fee, £6; or first year, £3 10s.; second year, £3. Clinical Medicine and Clinical Surgery, each £3 6s. Pathological Anatomy, £2 2s.—A three months' course of Practical Ophthalmology is given in summer by Dr. A. Ogston.—The General Dispensary and the Lying-in and Vaccine Institution, and the Eye Institution, are open daily.—Clinical instruction is given in the Royal Lunatic Asylum for three months in the year.

**UNIVERSITY OF EDINBURGH.**—Annual Fee for each subject required in the ordinary curricula, £4 4s.; except Anatomical Demonstrations, £1 1s.; Practical Pharmacy and Dispensary, each £2 2s.; Practical Anatomy and Practical Chemistry, each £3 3s.—Every Student, before entering with any Professor, must produce a matriculation ticket for the ensuing session, for which a fee of £1 is paid at the beginning of each winter session.—The Library is open every lawful day during the winter session, from 10 A.M. till 4 P.M.; on Saturdays, till 1 o'clock.

**EDINBURGH ROYAL INFIRMARY.**—Fees: 6 months, £3 3s.; 1 year, £5 5s.; perpetual, £10 10s. Clinical Medicine and Clinical Surgery, each £4 4s. for the course.—No fees for any medical or surgical appointment. Four Resident Physicians and four Resident Surgeons are appointed; they live in the house for six months free of charge. Can-

didates must be registered as legally qualified practitioners. Non-resident Clinical Clerks are appointed. Each surgeon appoints from four to nine Dressers for six months. Assistants in the Pathological Department are appointed by the Pathologist.—Instruction is given in special departments.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.**—The courses qualify for examination for various diplomas and licences, and for degrees in those years in which University residence is not required.

**Fees.**—For the first of each Winter Course of Lectures, £3 5s.; second, £2 4s.; perpetual, £5 5s. To those who have already attended a first course in Edinburgh, the perpetual fee is £2 4s. Second Course of Midwifery, £1 3s. Practical Chemistry and Practical Anatomy, £3 3s. Anatomical Demonstrations, £2 2s.; when taken along with Practical Anatomy, £1 1s.; perpetual, £4 4s. Analytical Chemistry, £2 a month, £5 for three months, or £10 for the session of six months. Vaccination, £1 1s. Summer courses of Clinical Surgery, Clinical Medicine, Practical Anatomy, Operative Surgery, and Diseases of the Eye, each £2 2s.—The minimum fee for the education for the double qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh, including the examination fee, is £90 4s., payable by yearly instalments; for the single diploma of either Physician or Surgeon, including the examination fee, £80.

**Practical Instruction.**—Royal Infirmary, noon daily; perpetual, £10; annual, £5 5s.; separate payments for two years entitle the student to a perpetual ticket.—Sick Children's Hospital: three months, £1 1s.; perpetual, £2 2s.—Dispensary: Royal Public Dispensary and New Town Dispensary, each, first six months, £3 3s.; three months, £2 2s.; each subsequent three months, £1 1s.—Practical Midwifery: Royal Maternity Hospital, Royal Public Dispensary, £1 1s.; New Town Dispensary, £1 3s.—Diseases of the Eye, Ear, and Teeth: Dispensaries, and the Edinburgh Eye Infirmary.—Practical Pharmacy: Royal Public Dispensary, New Town Dispensary, six months, £3 3s.

**UNIVERSITY OF GLASGOW.**—Fees, each course, £3 3s.; except Lectures on the Eye, £1 1s.

**GLASGOW ROYAL INFIRMARY.**—Fees, 1st and 2nd year, each £3 3s.; 3rd year, and perpetual, £1 1s.; 6 months, £2 2s.; 3 months, £1 1s. 6d. Vaccination, £1 1s.; Practical Pharmacy (6 months), £3 3s. Clinical Lectures in Medicine or Surgery: 1st and 2nd winter course, each £3 3s.; 3rd course, £1 1s.; summer course, £1 1s. 6d.

**GLASGOW EYE INFIRMARY.**—Fee, 6 months, £2 2s.; to students who are attending or have attended the Lectures on the Eye in the University, £1 1s.

Instruction may also be obtained at the Glasgow University Lying-in Hospital and Dispensary for Diseases of Women and Children; and at the Dispensaries for Diseases of the Skin and Ear; and the Royal Lunatic Asylum, Gartnavel, is open to students on payment of a small fee.

**GLASGOW—ANDERSON'S UNIVERSITY.**—Fees for all the Lectures and Hospital Practice required for the Diplomas of Physician and Surgeon, £45. Class Fees for each Course of Lectures: 1st session, £2 2s.; 2nd session, £1 1s.; afterwards free. Anatomy Class Fees, for Lectures and Demonstrations: 1st session, £4 4s.; 2nd session, £4 4s.; perpetual, £8 8s. The Dissecting-room is free for two sessions to those who attend both courses of Anatomy. After the second year, the fee for admission to the Dissecting-room is £1 1s. per session. There is a Matriculation Fee of £1 1s. at the beginning of each Winter Session.

**THE MIDDLESEX HOSPITAL.**—The annual dinner of the past and present students and friends of the Middlesex Hospital will take place on Monday, October 2nd; Thomas Taylor, Esq., in the chair.

**REQUESTS, DONATIONS, ETC.**—Mr. Giles Loder bequeathed £5,000 to the Salisbury Infirmary.—Sir Arthur Guinness has given £500 towards the erection of a new building for infectious diseases, &c., adjoining the Coombe Lying-in-Hospital, Dublin.—The Leicester Infirmary has received £300 under the will of Mr. H. R. Hurst.—“A Generous Lady” has given £200 to the Infirmary for Epilepsy and Paralysis, Charles Street, Portman Square.—The General Hospital, Birmingham, has received £100 for the Accident Fund, under the will of Miss Alton.—“A Lady” has given £100 to the Royal Infirmary for Children and Women, Waterloo Road.—Mr. Thomas Williamson, of Lixmount, bequeathed £20,000 to the Leith Hospital.—The Essex Hall Asylum for Idiots, Colchester, has received £250 “in memory of the late Mr. John Crabtree, of Halesworth.”

PROFESSOR LISTER has been summoned to Balmoral to open a small gathering on Her Majesty's arm.

WE are requested to state that St. Thomas's Hospital, Albert Embankment, is now open for the reception of patients.

THE Honorary Financial Secretary to the British Medical Benevolent Fund has received from E. Parke, Esq., of West Derby, Liverpool, a donation of £20 for the purposes of the Fund.

WE regret to hear that Dr. Page of Kirkby Lonsdale has met with a severe fall from a horse; from which he is, however, recovering under the care of Dr. Longmore and Dr. Bickersteth of Liverpool.

OUR readers will be glad to learn that the revision of the *Lectures* of Sir Thomas Watson by their author has been completed. We hear that the last pages are in the hands of the printer, and that the publication of the new edition may be looked for at an early date.

WE regret to learn from Mr. J. Wickham Barnes that the President of the Poor-law Medical Officers' Association, Dr. Joseph Rogers, has been obliged to relinquish for a short time all duties connected with the Association, and his own practice, owing to a local disorder requiring surgical treatment.

THE Duchess Dowager of Northumberland, accompanied by the Duchess of Northumberland, visited the Prudhoe Memorial Convalescent Home at Whitby on the 5th of September. Their graces were received and conducted over the institution and grounds by Dr. Philipson, one of the Honorary Secretaries.

#### THE EPIDEMIC OF TYPHUS IN VIENNA.

THE epidemic of typhus which has recently prevailed in Vienna is now considered to have come to an end; and consequently the authorities of the suburbs have been released from the obligation to provide fever hospitals, and the restriction against receiving fever-patients into the general hospitals has been removed. The epidemic has lasted twenty-one weeks, during which time 1766 typhus patients, of whom 366 died, were received into the three great hospitals of Vienna.

#### JENNER AND HIS TEACHINGS.

DR. A. B. STEELE of Liverpool, a well-known authority on Vaccination, wishes to correct a misapprehension into which Dr. Davey has fallen in reference to Jenner's views as to the degeneration of lymph by mere lapse of time. A reference to the tenth chapter (p. 177 et seq.) of Dr. Seaton's Handbook of Vaccination, will show that "the hypothesis dates from a very early period of the history of vaccination, and applications for lymph were made to Jenner within two or three years from the promulgation of his discovery. He thought it of no importance whatever to comply with the exact terms of such requests, for he was well satisfied, from his experience at that time, that no such deterioration had then taken place. Further experience—a careful watching of vaccination for upwards of twenty years more, during which lymph, successively transferred from subject to subject, had undergone no change whatever in its qualities—fully satisfied him that the hypothesis was groundless." So much for Jenner's opinion. Marson, Ceely, and others, whose experience is very great, have proved, so far as such matters admit of proof, that, as the National Vaccine Board stated in 1854, "vaccine lymph does not lose any of its prophylactic power by a continued transit through successive subjects." When lymph degenerates in transmission, it is invariably due either to want of proper care in the selection of subjects, or to inattention to certain details essential to successful vaccination. As to grease in the horse as the source of cowpock, it is quite true that Jenner at first confounded "grease" with the true "variola equina"; but subsequently he discovered his mistake. That cowpock does originate, and can be produced, quite independently of any source from the horse, is well known to all who are acquainted with the literature of the subject.

#### THE ADDRESS IN MEDICINE.

DR. GEORGE JOHNSON writes (August 21st), in reply to Dr. Wade:—"In reply to Dr. Wade's letter, I beg to say that, if I have misinterpreted the quotation from his lecture, I sincerely regret it; let me add, however, that if his intention was not to call in question the doctrine of the elimination of morbid poisons, it is difficult to understand the meaning and object of the passage. In referring to lead-colic, small-pox, and scarlet fever, my object was not to call in question Dr. Wade's belief with regard to these particular diseases; but, on the contrary, by pointing to illustrations about which dispute is scarcely possible, to indicate the distinction between a disease and a morbid cause."

#### FAILURE OF CONDURANGO.

ALL that we hear of the results of the trials given to the Condurango bark furnished by our Government to the Middlesex and St. Bartholomew's Hospitals, through the College of Physicians, confirms the fear that any hope which might have been entertained, of a confirmation of the statement of its utility as a remedy in cancer, must be entirely dismissed. Physiologically, it appears to be practically inert, and its therapeutic effects in the treatment of cancer to be *nil*. It furnishes a slightly bitter extract of feeble characters. A detailed therapeutical report will be made by Mr. Hulke, and a careful examination of its physiological action by Dr. Brunton, but this mainly in deference rather to the official sources from which this small supply has been furnished, and to set at rest the excitement caused by the somewhat scandalous claims which have been set up in its favour.

#### HUMOURS OF THE AMBULANCES.

A feuilletonist of the *Gazette Médicale de Strasbourg* discusses the humours of the ambulances, which sometimes chequered the sad scenes that prevailed there. The Bavarian soldiers, struck, as are all foreigners, with the ubiquity of clyster-pumps and vaginal syringes in French establishments, large and small, began to utilise them after their fashion. In the ambulances of Dr. Rupprecht they used the long uterine-tubes, as cigar- or pipe-tubes, their flexibility rendering them very convenient and in the clyster-pumps they prepared, *horrible dictu!* soda-water with the effervescing powders they found in the abandoned pharmacies. Said a poor fellow wounded at Nuits, after receiving the sacrament, "C'est donc fini; on m'a ciré les bottes." A Pomeranian, whose leg had been shattered and then amputated, called, on waking from the chloroform, for his trousers, and began mending his purse and replacing the scattered money in it—*un obole pour Charon*.

#### FOUNDLINGS AT ST. PETERSBURG.

THE mortality of the great foundling hospitals of Europe was by no means exaggerated in the evidence given before the late Committee of the House of Commons on the Protection of Life. The Committee found some difficulty at first in accepting the statements laid before them as to the inevitable mortality attending aggregation of infants, no matter how carefully superintended, and the futility of any other system than that which should contemplate the dispersion of infants in individual homes, where each infant is under the care of a nurse or mother. M. de Valcourt, who is on a medical tour in Russia, describes the superb foundling hospital of Moscow, which receives something like ten thousand infants annually, and on which the utmost care and large state subventions are lavished. The melancholy result is a mortality of eighty per cent. in the first year of life.

#### HOW CHOLERA MAY COME.

IN the evidence on quarantine given by Mr. Arthur Helps, clerk to the Privy Council, in March last, before the Royal Sanitary Commission, he observed: "I do not think that it is possible to carry out quarantine with such a thing as cholera, without producing such a check upon the movement of the world in reference to transit, that it would be impossible. There must be quarantine between Dover and Calais to prevent cholera from coming." Mr. Tom Taylor, not less pointedly, observed with regard to quarantine: "It seems to me rather a political

than a sanitary question: it is a concession to the opinion of foreign countries." Now, we entirely concur in the efforts that are being made to enforce a cholera-quarantine against vessels coming from Baltic and other ports known to be infected; but we pointed out last week that the measures at present taken are extremely ineffectual, and capable of affording only an unreal sense of security. Of this, a circumstance which occurred at Sunderland on Saturday last affords an example. The schooner *Marshall* arrived, the captain having died on board of cholera on August 15th. The ship was allowed, owing to the pilot not reporting it, to moor at the North Quay before inspection. Dr. Douglas, the medical officer, lays stress upon what we have already urged, that it is of comparatively little use to stop and disinfect ships, when the crew cannot be prevented from going on shore and disseminating whatever infectious influence they may bring with them. Let us, by all means, endeavour to secure a really efficient quarantine. To hide our heads in the quarantine-bush, and expose more vulnerable parts, is a purely ostrich-like proceeding.

#### PARASITES IN FOOD.

THE extremely interesting Cantor Lectures delivered by Dr. Cobbold, F.R.S., before the Society of Arts, on Food-producing Ruminants and the Parasites which reside in them, have been reprinted from the *Journal of the Society of Arts* in a separate form. They are worthy of an extended circulation, and are particularly interesting to medical men and officers of health. His observations on tapeworms in beef have an immediate practical value in relation to India, and a possible importance, which cannot be overlooked, as to the effects of sewage-irrigation in this country.

#### THE HARVEIAN ORATION, 1871.

THE writings of Dr. T. K. Chambers have always found peculiar acceptance with our brethren across the Atlantic; and no other contemporary medical writer is more highly esteemed by them, or more generally read. His Harveian Oration of 1871 was laid before our readers at the time of its delivery. It now reaches us in a separate form, with two sequels, bearing the imprint of an American publisher (Lea of Philadelphia), and with the following preface.

"For upwards of two centuries the London College of Physicians complied with the letter of Harvey's wishes, as expressed in his Deed of Gift, by causing an annual oration to be delivered in Latin. But during the last few years there has been a growing conviction that, in this pedantic adherence to the words, we were departing from the spirit, of the founder of the ceremony, the object of which is to stir up the audience to a diligent study of physiology and to professional *esprit de corps*. An 'exhortation to mutual love and affection', as Harvey words it, was fitly enough of old couched in a language more familiar than all besides their own to the brotherhood of science in various countries. Is it too hurried an anticipation of nature to look upon English as now the most appropriate medium for circulating such exhortations among physicians in Europe? At all events, across the Atlantic and Pacific there are bands of relatives, whom we are much prouder to claim, and to exhort to mutual love and affection in a tongue that recalls the fact of blood being thicker than water. This year the oration, though delivered in England, shall be printed and published in America first. The offering is a poor one—then let it be repaid by a richer. No one can be more sensible than I am of the superficial manner in which several important questions are handled; but that very fact may lead others to more profound reflections. A judicious critic remarks that, in the sequel especially, the colouring is very local. True—otherwise it would be unnatural. And Americans have not the same troubles as we have. But they may have them soon. Let them listen kindly to the outpourings of our griefs, and we will promise to sympathise with theirs when they tell them."

We do not doubt that our American brethren will receive with pleasure this somewhat eccentric, but by no means ungraceful act of fraternity from the Harveian orator. Occurring almost simultaneously with the appearance of Dr. Lewis Sayre's lecture in our pages, it probably, and we hope immediately, forebuds a closer and more frequent interchange of personal and scientific courtesies amongst the medical thinkers of the two great Anglo-Saxon communities. The sequels, which exceed in length the oration, are colloquies between

imaginary personages, of whom Orator represents the author, on restorative medicine; the use, abuse, and prohibition of alcohol; female practitioners; empiricism; *et quedam alia*.

## THE CHOLERA.

### CHOLERA ON THE CONTINENT.

WE referred lately to the importance of ascertaining whether the present epidemic is due to a fresh importation from Persia (as is the opinion at Constantinople), or the recrudescence of the epidemic of 1865, which was imported from the ports of the Mediterranean into those of the Black Sea. A careful analysis of the official documents has since satisfied M. Pelikan, the director of the out-medical service in Russia, that we have to deal with the tail of the epidemic of 1865, which shows a great tenacity, and seems to have found in Russia the conditions favourable to its acclimatisation. Our own present danger is chiefly in the probability of importation from the Baltic ports. It is extremely unsatisfactory to read of the carelessness of quarantine regulations at the Helder (Nieuwe Diep), which might easily become the intermediary of cholera importation into this country; and we trust that our Government, warned of the danger, will redouble its own vigilance, and, if necessary, remonstrate with the Dutch authorities.

A correspondent of the *Pall Mall Gazette* at the Hague writes: "It is officially stated that at the Helder (Nieuwe Diep) a case of Asiatic cholera has occurred with a fatal result. The carelessness of our Government is most scandalous. Steamers and other vessels coming from Königsberg were allowed to enter the port without undergoing quarantine, and thence to proceed to Amsterdam. The steamer *Orion*, from Königsberg, was even allowed to enter the Amsterdam docks, although the master was obliged to stay at Elsinore in consequence of being attacked by cholera. There is a general shipping trade between Nieuwe Diep and London."

The Prussian correspondent of the *Times* devotes his letter of the 31st August to the progress of the cholera. Berlin, as yet free from the scourge, was fast being drawn within its deadly shadow. During the last few days fatal cholera cases had occurred at Dantsic, Elbing, Altona, Coblenz, Leipsic, and Vienna. In other words, the shores of the Baltic and the North Sea, the banks of the Rhine and the Danube, and the centre of Germany, have been simultaneously visited. The scourge continued to rage at Königsberg and in the neighbouring districts of East Prussia. At Königsberg about 140 persons were seized daily, of whom one-third succumbed. The intelligence from Russia concerning the progress of the epidemic is still very melancholy. At Moscow, according to the official report, 479 persons were suffering from the disease on August 21. Of these, 30 recovered on that day, and 23 died, leaving 426 under medical treatment. On the 22nd, there were 23 fresh cases, 22 recoveries, and 18 deaths. On the 23rd, the fresh cases amounted to 32, recoveries to 18, deaths to 19, those under treatment being 404. On August 26, the sum total of all those in Moscow seized since the beginning of the epidemic (March 13) was 5052. Of these, 2340 had recovered, and 2354 were dead. From the interior of Russia we have only fragmentary intelligence, which, however, is but too well calculated to reveal the immense extent of this year's epidemic. To begin with St. Petersburg, the total of those having the disease averages between 190 and 200 per day. There are daily twenty fresh cases, about as many recoveries, and twelve or fifteen deaths. Nor do the western and southern regions show any improvement. In Smolensk whole villages are said to be dying out.

The *Wiener Medizinische Zeitung* of August 29th, in giving a report of the progress of cholera, states that up to August 25th there had been four cases—all fatal—in Berlin. Three cholera hospitals have been prepared by the local authorities; and the small-pox hospital in Belle Alliance Place has been appropriated to cases of cholera occurring in the garrison. The Minister of Commerce has issued instructions to the directors of the railways to take prompt measures for the effectual disinfection of the *lieux d'aisance* at the stations. The Minister of War has issued a circular to the commanders of troops, recommending the adoption of such measures to prevent the spread of cholera in the army as were employed in 1864 and 1866. These measures comprised regulations as to diet, clothing, medicine, etc. In the case of an outbreak of the disease in the army, it is in contemplation to use as hospitals the barracks employed for the reception of prisoners and wounded in the late war.

In Lithuania, says the *Wiener Medizinische Wochenschrift* of Sept. 2nd, cholera has spread with undiminished intensity; and has, it is said, proved fatal in more than half of the cases. In Wilna, the disease has

caused many deaths among the well-to-do classes, including the wife of Governor-General Polapow. Its greatest devastations have, however, taken place among the crowded Jewish population, and among those of the native inhabitants who are addicted to intemperance in drink.—The first case of cholera was reported to have occurred in Hamburg on August 28.

The *Wiener Medizinische Zeitung* of August 29th states that the report that several cases of Asiatic cholera had occurred in Vienna, was incorrect.

## ASSOCIATION INTELLIGENCE.

### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEDICAL MEETING.

THE next meeting of the members of the above District will be held at the Church Institute, Cavendish Street, Ramsgate, on Thursday, Sept. 14th, 1871, at 2 o'clock: JOS. AUSTEN, Esq., R.N., in the Chair.

Dinner will be provided at the Granville Hotel at a quarter to five o'clock precisely. Charge 5s., exclusive of wine.

All members of the South Eastern Branch are entitled to attend, and to introduce friends.

Notices have been received of the following communications to be read at the meeting:—1. Selection of Surgical Cases: with Remarks. By R. Hicks, Esq.—2. Case of Abdominal Aneurism, with Gangrene of Right Leg. By S. Woodman, Esq.—3. Case of Laceration of Vagina from Fracture of Glass Injection-Syringe. By C. Parsons, M.D. Gentlemen who intend to be present at the dinner, are particularly requested to inform me on or before Tuesday, the 12th instant.

CHARLES PARSONS, M.D., *Honorary Secretary*.

2, St. James's Street, Dover, Sept. 5th, 1871.

### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEDICAL MEETINGS.

A MEETING of the members of the above District will be held at Hastings, in the afternoon of Wednesday, the 27th instant.

All members of the South Eastern Branch are entitled to attend, and to introduce friends.

As the District Honorary Secretary, Mr. Mudd (being about to leave Uckfield), will resign, it will be necessary to appoint his successor at this meeting.

Gentlemen who wish to make communications to the meeting, are requested to inform me *at once*, in order that a notice thereof may be included in the circular convening the meeting.

G. F. HODGSON, *Hon. Sec. of the South Eastern Branch*.

52, Montpelier Road, Brighton, Sept. 6th, 1871.

### THE ANNUAL MEETING, 1872.

A SPECIAL general meeting of the Birmingham and Midland Counties Branch was held at the Midland Institute on August 31st; Oliver Pemberton, Esq., President, in the chair. A General Committee of members of the Branch was appointed to make the necessary arrangements for the reception of the British Medical Association at their annual meeting in 1872. Mr. S. A. Bindley and Mr. Thomas Taylor were elected Treasurers of the Special Donation Fund. Mr. T. H. Bartleet, Dr. B. W. Foster, and Mr. J. F. West, were elected Secretaries. Mr. Bartleet stated that the donations already promised amounted to more than £500.

### EXCURSION TO TORQUAY.

AMONG the most pleasant and enjoyable of the holiday events of the recent annual meeting was the excursion to Torquay, organised in favour of those who responded to the invitation from the practitioners of Torquay, inserted in the *JOURNAL* for a fortnight preceding the meeting. No formal notice of it has reached us from those concerned in organising it, or from any other source; but we hear from many quarters how cordial, thoughtful, and liberal, was the reception; how ample the arrangements for pleasure and comfort; and how much the numerous party who visited Torquay are indebted to their brethren there. We hear from the Rev. Dr. Haughton of Dublin, who, with Dr. Beatty and Mr. Macnamara, was an honoured and welcome guest, a follows. "As one of the sixty or seventy visitors who partook of the hospitality of the profession in Torquay, I wish to record my gratitude. It was one of the pleasantest meetings I have ever assisted at; and was admirably presided over by the venerable Dr. Evanson. The civilities

received by us were not conferred by the members of the profession only; and none of us will readily forget Mr. Pengelly's lecture among the celebrated bone beds of Kent's Cavern."

## MEDICAL NEWS.

UNIVERSITY OF LONDON.—First M.B. Examination, 1871. Examination for Honours.—Anatomy.

#### First Class.

Schafer, Edward Albert (Exhibition and Gold Medal), University College  
Branfoot, Henry Seymour (Gold Medal), Guy's Hospital

#### Second Class.

Rayne, Charles Alfred, University College  
Skerritt, Edward Markham, B.A., University College  
Physiology, Histology, and Comparative Anatomy.

#### First Class.

Schafer, Edward Albert (Exhibition and Gold Medal), University College  
Skerritt, Edward Markham (Gold Medal), University College  
Organic Chemistry and Materia Medica and Pharmaceutical Chemistry.

#### First Class.

Branfoot, Henry Seymour (Exhibition and Gold Medal), Guy's Hospital  
Firth, Charles (Gold Medal), St. Bartholomew's Hospital  
Buchanan, Arthur, Guy's Hospital

#### Second Class.

Rayne, Charles Alfred, University College  
Dodson, Andrew, Queen's College, Birmingham  
Smith, George Francis Kirby, Guy's Hospital  
Schafer, Edward Albert, University College  
Skerritt, Edward Markham, University College

First B.Sc. and Preliminary M.B. conjointly. Examination for Honours.—Chemistry.

#### First Class.

Elwes, John Wm., Prel. Sci. (Exhibition), University College

#### Second Class.

Richmond, James, First B.Sc., Manchester Grammar School  
Atkinson, R. W., First B.Sc., University College, and Royal School of Mines.

#### Third Class.

Titmas, Samuel David, Prel. Sci., University College  
Verco, Joseph Cooke, Prel. Sci., St. Bartholomew's Hospital  
Carnelly, Thomas, First B.Sc. and Prel. Sci., Owens College  
Ferrand, Edward, Prel. Sci., St. Bartholomew's Hospital  
Jones, Cyril Lloyd, Prel. Sci., Guy's Hospital  
Langley, John Geoffrey, Prel. Sci., University College

### Zoology.

#### First Class.

Saunders, John Chas., Prel. Sci. (Exhibition), Downing College, Cambridge

#### Second Class.

Harrison, Chas. Edward, Prel. Sci., St. Bartholomew's Hospital  
De Watteville, Baron A., M.A., First B.Sc. and Prel. Sci., University College

#### Third Class.

Jones, Cyril Lloyd, Prel. Sci., Guy's Hospital  
Edwardes, Edward Joshua, Prel. Sci., Private study

### Experimental Physics.

#### Second Class.

Poynting, John Henry, First B.Sc., Owens College  
Atkinson, R. W., First B.Sc., University College, and Royal School of Mines.

#### Third Class.

Richmond, James, First B.Sc., Manchester Grammar School

### Botany.

#### First Class.

Moore, Spencer Le Marchant, Prel. Sci. (Exhibition), University College

#### Third Class.

Pepper, Augustus Joseph, Prel. Sci., University College

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, August 31st, 1871.

Blok, Moses, New Burlington Street, W.  
Day, Gordon Cleghorn, Bridport  
Jessopp, John, Felix Pelham, Herts  
Turner, Horace, Middlesex Hospital

The following gentlemen also on the same day passed their first professional examination.

Bradbury, John Batley, Leeds School of Medicine  
Eminson, Luther, University College  
Greaves, Frank, Middlesex Hospital  
Palmer, Montagu H. C., St. Thomas's Hospital  
Ward, Joseph, Queen's College, Birmingham

### MEDICAL VACANCIES.

THE following vacancies are announced:—

ATCHAM UNION, Salop—Medical Officers for the St. Chad's and St. Mary's Districts.

BATTLE UNION, Sussex—Medical Officers for the Mountfield and Brightling Districts.

BETHLEM HOSPITAL—Two Medical Students.

BRISTOL LUNATIC ASYLUM, Stapleton—Assistant Resident Medical Superintendent.

**BRISTOL POLICE**—Surgeon.  
**CLOCHER UNION**, co. Tyrone—Medical Officer for the Augnacloy Dispensary District.  
**CORK**—Medical Officer of Health.  
**COURT STAR OF ROSELAND**, 4666, St. Mawes, Cornwall—Medical Officer.  
**DOVER HOSPITAL AND DISPENSARY**—House-Surgeon.  
**GORT UNION**, co. Galway—Apothecary for the Workhouse and the Gort Dispensary.  
**GAINSBOROUGH DISPENSARY**—House-Surgeon.  
**GOWER UNION**—Medical Officer and Public Vaccinator for the Western District.  
**ISLINGTON**—Medical Officer of Health and Analyst.  
**KENT AND CANTERBURY HOSPITAL**—Assistant House Surgeon and Dispenser.  
**LIVERPOOL**, Parish of—District Medical Officer.  
**MIDDLESEX HOSPITAL**—Resident Physician's Assistant.  
**NARBERTH UNION**, Pembrokeshire—Medical Officer and Public Vaccinator for District No. 3.  
**NORTHERN HOSPITAL**, Liverpool—Physician.  
**NORTH RIDING INFIRMARY**, Middlesbrough-on-Tees—Honorary Medical Officer.  
**REETH UNION**, Yorkshire—Medical Officer and Public Vaccinator for the Muker District.  
**ST. SAVIOUR'S UNION**, Surrey—Medical Officer for District No. 3.  
**SOUTHAMPTON UNION**—Medical Officer for District No. 2.  
**TENTERDEN UNION**, Kent—Medical Officer for the Biddenden District.  
**WEST LONDON HOSPITAL**—House-Surgeon.  
**WESTMEATH COUNTY INFIRMARY**, Mullingar—Surgeon.  
**WORKSOP DISPENSARY**—Resident Surgeon.  
**YORK UNION**—Medical Officer and Public Vaccinator for District No. 4.

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

**HARBORN**, A. D., Esq., appointed Medical Officer of the Northern District Post Office, Islington, *vice* W. C. Tiley, Esq., resigned.  
**MACK**, John Steele, L.R.C.S. Edin., appointed Medical Officer and Public Vaccinator for Lochgoilhead and Kilmorich, Argyleshire.  
**MADIGAN**, John Francis, L.R.C.P. Edin., appointed Medical Officer, etc., for the Feenagh Dispensary District of the Newcastle Union, co. Limerick.  
**MAY**, Dr. James, appointed Parochial Medical Officer and Public Vaccinator for Aberfoyle, Perthshire.  
**ORWIN**, Arthur W., Esq., appointed Resident Obstetrical Officer to the Charing Cross Hospital, *vice* S. S. Noakes, Esq., resigned.  
**POTHAM**, Thomas, L.K.Q.C.P.I., appointed Medical Officer, Public Vaccinator and Registrar of Births, to the Cliffove Dispensary, co. Sligo.  
**RUTHERFORD**, David J., M.D. Edin., elected Medical Officer for the Eastern Division of the Omagh Dispensary District of the Omagh Union, co. Tyrone.  
**WOODWARD**, Edwin, Esq., appointed Admiralty Surgeon and Agent for King's Lynn, *vice* T. M. Kendall, F.R.C.S., deceased.

### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3d. each, which should be forwarded in stamps with the communication.*

#### BIRTHS.

**EDYE**—On August 24th, at Exeter, the wife of \*Stonard Edey, Esq., Surgeon, of a son.  
**MONTAGUE**—On August 22nd, at the Central Barracks, Woolwich, the wife of \*T. B. Montague, M.D., of a daughter.  
**THOMPSON**—On September 3rd, the wife of \*John Thompson, L.R.C.P. Edin., of a daughter.  
**TELFORD**—At Leewood Crescent, Leamington, on September 3rd, the wife of \*A. W. Telford, M.D., of a son.

#### MARRIAGE.

**RHODES**, T. Wemyss, Esq., of Manchester, to Emma, second daughter of James Russen, Esq., of Rusholme, Manchester, on August 29th.

#### DEATH.

**PIKE**, Joseph, M.B., at Leamington, aged 29, on August 27th.

### BOOKS, ETC., RECEIVED.

*The Annual Report on the Health of the Parish of St. Marylebone, 1870.* By John Whitmore, M.D. London: 1871.  
*Lichfield and its Neighbouring Places of Clare.* By E. D. Mapother, M.D. London and Dublin: 1871.

### OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.  
**WEDNESDAY** ..... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**THURSDAY** ..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.  
**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.  
**SATURDAY** ..... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

### NOTICES TO CORRESPONDENTS.

*ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.*

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS.**—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with *halfpenny* stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**MR. GREENWAY** (Plymouth).—The plan, etc., can accompany the full text of the paper.

**DR. JAMES DANIEL'S** (Haslar Hospital) wish shall be attended to.

#### HOSPITAL APPLIANCES.

WE have before us a correspondence addressed by Messrs. Masters and Sons of New Kent Road to the secretary of a metropolitan hospital, suggesting that, for the supply of instruments and appliances, it would be desirable that hospitals should go more directly to the makers—trusses from truss-makers, limbs from limb-makers—instead of issuing orders through intermediate persons, who add to the prices, and interfere with the ultimate fitness of the articles. This is a matter for individual consideration, with which we do not feel called upon to interfere, further than by directing attention to the suggestion.

**NOTICE TO ADVERTISERS.**—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to **MR. F. H. HEATHCOTE**, not later than *Thursday*, twelve o'clock.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, Sept. 2nd; The New York Medical Record, August 25th; The Boston Medical and Surgical Journal, August 25th; The Madras Mail, June 24th; The Shield, September 2nd; The Philadelphia Medical Times, July 17th; The Philadelphia Medical Independent, August 19th; The Birmingham Morning News, Sept. 1st; The Irish Times and Daily Advertiser, August 30th; The Western Times, Sept. 1st; The Western Morning News, Sept. 1st; The Freeman's Journal, Sept. 6th; The Norwich Argus, Sept. 2nd; etc.

**COMMUNICATIONS, LETTERS, ETC.**, have been received from:—

Dr. Wallace, Liverpool; Mr. O. Penfold, Sandhurst, Victoria; Dr. G. Johnston, Dublin; Dr. Robert Perry, Glasgow; Dr. Gairdner, Glasgow; Our Dublin Correspondent; Dr. J. I. Mackenzie, Sidmouth; Mr. G. Birt, Leamington; Mr. H. Kerbey, London; Dr. Nicol, Bradford; Dr. G. Johnson, London; Mr. Benson Baker, London; Dr. E. J. Cooke, Worksop; Mr. T. H. Bartlett, Birmingham; Mr. Townshend, Weston-super-Mare; Mr. Wickham Barnes, London; Mr. S. Barnett, Leominster; Mr. A. G. Chattaway, Leominster; Dr. Steele, Liverpool; Dr. Robert Barnes, London; Mr. H. Palmer, King's Lynn; Mr. Stonard Edey, Exeter; Mr. E. Lloyd, London; Mr. James Haworth, Filey; Our Manchester Correspondent; Mr. Blair, Worcester; Mr. Aspin, Preston; Mr. C. S. Webber, London; Dr. Greenhow, London; Dr. J. G. Macbeth, Lucknow; Mr. Bruce, London; Dr. Woodman, London; Dr. R. Simpson, Plymouth; Dr. Hughes Bennett, Edinburgh; Mr. Andrew Davies, Swansea; Dr. J. ## REMARKS

ON THE

## PRUSSIAN SIEGE OF PARIS

IN SOME OF ITS RELATIONS TO HYGIENE AND SURGERY.\*

By DEPUTY INSPECTOR-GENERAL C. A. GORDON, M.D., C.B., etc.,  
Late on Special Service with the French Army.

ON the outbreak of war between France and Prussia in 1870, I had the honour of being accredited to the French army as Commissioner,† charged with the duty of inquiring into and reporting upon the systems of sanitary and medical administration followed in that service, and investigating such matters of surgical interest as should present themselves.

On my arrival in Paris on the 2nd September, to obtain from the authorities the necessary credentials to enable me to join the army under Marshal Macmahon, rumours were already in circulation in reference to the critical position of that force and its commander, and on the following day the news of the disaster at Sedan was publicly known throughout the capital.

On the 4th, the all but bloodless revolution took place, resulting in the deposition of the Imperial, and the declaration of a Provisional Government. Then followed rumours that negotiations were in progress and the war about to end—rumours which were speedily shown to be groundless—and the rapid progress of events sufficiently clearly indicated that Paris must prepare for a siege. That event, which early in September was a probable contingency, has now passed into history.

The steady approach of the Prussian army; the hurried accumulation of such stores of food within the city as were obtainable; the *levée en masse* of the population for purposes of defence; the enormous exertions made to strengthen the lines of fortifications immediately around and at a little distance from the capital; the endeavours made to provide the effectives with clothing, arms, accoutrements, and to obtain suitable accommodation for troops and contingents; and the gigantic scale upon which arrangements were made for sick and wounded, have all been more or less completely described, although mere description would fail to convey the actual impression of the whole, such as could alone be obtained by an eye-witness.

It would be impossible in a paper of the length to which the present must be restricted, to do more than enter very briefly into some matters connected with the points just enumerated; nor do I omit to observe that, while all of them come more or less directly within the province of the army medical officer, only two or three have reference to the great mass of the profession as represented by its members in civil life. Yet I trust the further observations I am about to offer in regard to the experiences of the siege of Paris may present some points of interest to both classes of my professional brethren; namely, to those in the public service and to those in private life. For the sake of convenience, I shall allude to the topics to be glanced at in the following order.

1. *Physique of the Troops and Contingents.*—Great exertions were undoubtedly made to bring under arms every man capable of military service. Persons of all social conditions were drafted into the ranks; the grey-headed man of fifty-five stood along-side the youth of eighteen, or even less, if we could judge from the appearance of many; nor were the lame and the misshapen exempt from the general obligation to serve in the great emergency which threatened. A *corps d'armée*, consisting of the regular soldiers of the line, entered Paris soon after the Provisional Government was declared; new battalions were quickly formed, raising the nominal strength of the line troops in the capital to upwards of 50,000; the Gardes Nationaux and Mobiles making a strength upon paper estimated at about 475,000, upon whom the defence of Paris rested. Of the contingent forces, a considerable number brought in the early days of the war from the provinces of France consisted for the most part of strong athletic men, although even among them there were many whose *physique* appeared but ill suited to the requirements of severe service during winter. The young men drafted into reserve battalions of the line were, in a large proportion of instances, undeveloped lads. The civic forces themselves contained, with some excellent

materials as soldiers, very much that was utterly unsuited in bodily strength for the hardships of a campaign. Nor can I omit to allude to two other points, which, although not strictly medical in their bearings, have, nevertheless, a very suggestive bearing, if applied to our own military institutions. These drafts were hurriedly brought together; they were imperfectly drilled; they had not time to learn, practically, how much each could perform; self-reliance was still absent; nor were they able to acquire that mutual confidence in each other and in their officers which in reality distinguishes the old soldier from the mere recruit. The officers in many instances, even when the armies of the enemy were steadily closing in around Paris, and after the state of siege had been established, were oftener to be seen pursuing their own gratification than drilling their men. Among the civic forces the officers were elected by the men whom they commanded; and to these combined causes we may, I think, fairly attribute much of the disasters, in a military sense, which happened to the Parisian army in its various collisions with the more powerful, better trained, and self-reliant enemy, as well as the severe losses in killed and wounded which occurred on those occasions.

2. *Clothing of the Troops.*—In the hurry which necessarily attended the formation of the army of the defence, considerable difficulty evidently existed in the process of supplying the whole with suitable and sufficient clothing. The result was that, as the intensity of the winter of 1870 came on, the requirements of the troops were in these respects undoubtedly defective.

Great exertions were undoubtedly made to supply their wants; and, considering all things, it is a matter of wonder how so much clothing as was furnished could have been so quickly obtained. Subscriptions and donations by individuals and societies, moreover, came to the aid of the troops in this as in other respects; yet the fact must, I fear, be admitted, that much suffering and considerable mortality resulted during winter from deficient clothing of the troops when employed in the advanced posts and bivouacking upon and near the fields of battle.

3. *Food.*—Among all the trials to which the occupants of Paris, whether soldiers or civilians, were subject during the protracted siege, the gradually diminishing supply of food was undoubtedly the greatest. Notwithstanding the exertions made to provide ample stores before the investment of the city was complete, and the careful scrutiny that was made of the quantity of food in store, not more than a supply for two months' consumption was estimated to exist; yet the siege really continued for more than double that time. Little by little the supply of various articles was lessened. A careful census of the population was made; and food, whether in the shape of meat or bread, issued in accordance with official cards issued by the different *mairies*.

During the second half of the siege, the public health undoubtedly suffered in consequence of the insufficient and inappropriate food issued; and the effects experienced by us all, in greater or less degree, deserve, I think, to be alluded to here. The insufficient supply of animal food, superadded as it was to the want of fuel, rendered us little capable of withstanding the unusual intensity of cold which prevailed in Paris as elsewhere during the winter of 1870-71. However much clothing we put on, the result was not satisfactory. Our sensation of cold was never absent; yet, with the exception of those, especially the soldiers, who were directly exposed to the hardships of the field, chest-affections and attacks of rheumatism were by no means so prevalent as might have been expected. Cases of frost-bite among the military, especially those who had to bivouack, were both numerous and severe; the liability to be thus affected being increased by insufficient food added to insufficient clothing.

Scurvy in one form or other occurred, and prevailed to a considerable extent among the various classes of persons besieged. Some of the troops, especially those occupying Forts Vanvres and Issy, suffered from the affection in its pronounced form; they having suffered not only from insufficiency of food, but also from the fatigue, exposure, and mental strain incidental to the heavy and continuous bombardment to which for many weeks those forts were subjected by the Prussian batteries on the heights beyond.

Among the ordinary residents in the city the diathesis was readily detected. In some, the condition of the gums at once indicated its existence; in others, it manifested itself in purpurous patches on the surface. Some suffered from hæmorrhages; and all suffered more or less from inactivity and impaired power of undergoing much exertion—a state in part owing, no doubt, to deficient food, but also, in a measure, to inappropriate diet.

On the subject of preserved meat as an article of food, a few remarks are here demanded. Considerable stores of meat, prepared and preserved in tins, existed throughout Paris in the early part of the siege; and as the supplies of fresh meat became exhausted, many persons had to fall back partially or entirely upon the preserved. For a time every

\* Read before the Surgical Section at the Annual Meeting of the British Medical Association, in Plymouth, August 1871.

† Surgeon-Major Wyatt of the Coldstream Guards was my able coadjutor on the occasion.

confidence was entertained that the tinned meat was in all respects a complete substitute for the fresh. Nor did doubt for some little time arise on the subject; and, with the aid of condiments of various kinds, and the exercise of a little ingenuity, the besieged were able to indulge in savoury, if not very extensive or varied, meals. But it began to be felt that, somehow or other, the meals ceased to satisfy; there was a constant desire for food experienced; and, as already observed, the power of resisting cold and withstanding fatigue gradually diminished; diarrhoea became prevalent; dyspepsia and acidity were very generally complained of; and emaciation took place so that the clothing of all hung loosely upon them.

I am quite aware of the great importance which attaches to the question now glanced at, and to the great interests connected with its investigation. This consciousness induces me to avoid speculation and adhere simply to facts within my own knowledge, leaving the hearers or readers of this paper to draw their own conclusions, in regard to how far it may be desirable to trust to stores of preserved meat alone on long voyages or in campaigns.

4. *Accommodation for Troops.*—The troops of the regular army who occupied Paris were accommodated in the ordinary barracks throughout the city, in huts erected for their reception in the open spaces and along the principal thoroughfares, and in tents of various kinds issued temporarily for their use. The National Mobile Guards brought up from the provinces found quarters in hotels, private houses, and some also in huts; the National Guards raised in the capital being for the most part permitted to reside at their own houses, except when the turn came for the battalions to which they belonged to go to the front. The Garde Mobile Sédentaire, consisting for the most part of men who, on account of age or family considerations, were not required to go beyond the ramparts, went from their own houses on duty, and when that was over returned to their homes; yet the sight of the entire manhood of a city in uniform was a remarkable one: attendants in shops, cafés, and restaurants, the hairdressers, even the very porters in the streets, were in uniform; and, for the time being, the little boys played at soldiers, carried toy-knapsacks, and drilled with their toy-chassepots.

The question of accommodation has a very important bearing upon health. It had during the siege, and thus demands some remark here. The system of *caserment* of soldiers in France, although in theory perfect, is, in regard to principles of sanitation, extremely faulty. In a barrack the troops are arranged by *squads* and by *sections*; one large compartment of a building being set apart for the accommodation of thirty-two men, each floor of a barrack-building for six such sections, or, in other words, three companies. An apartment of the kind is divided in the middle transversely by a wooden screen about six feet and a half high; the bedsteads being arranged four and four from the walls at each end, and from the screen in such a manner that each side of the central passage through the rooms contains eight men—that is, a corporal and seven men, who are in a manner isolated from the others, and in some degree complete in themselves as a body. The disadvantage in the arrangement, however, is that, the men's beds being placed so as to extend from the transverse instead of the longitudinal walls, free perfilation of air can never be so complete as it is in English barracks, and hence all the usual effects of insufficient ventilation occur.

The huts erected were for the most part extremely flimsy in their nature; their occupants were unprovided with other bedding than a quantity of straw upon the long guard-beds upon which they slept, and their own blanket and greatcoat. Means of cooking were sufficient, but other requirements and outhouses were wanting. *Tentes abri* were only made use of to a small extent, and when employed were of little real use as a protection against the weather. In fact, it is more than questionable whether, during the Franco-Prussian war, any little advantage that might have arisen from their employment was not far more than counterbalanced by the evils arising from their weight, not to speak of the time required to pitch and fold them up again.

5. *Provision for Sick and Wounded.*—Great as were the exertions made to render the defences of Paris effective against a siege, scarcely less in their nature were those undertaken by the Intendance and by various philanthropic associations for the accommodation and care of expected sick and wounded. It was felt that the duty was imperative of making the arrangements for preserving the life of friends as efficient in their way as those for the destruction of enemies were in theirs; and it may be truly asserted that, on this occasion, expense on the part of societies and individuals was considered altogether secondary to the great mission of imparting to sick and wounded the greatest amount of comfort, attention, and assistance possible. There is, unfortunately, difficulty in obtaining definite information as to the precise extent of accommodation provided in hospitals, appropriated buildings, private houses, huts, tents, etc., for sick and wounded. After a time a considerable

amount of what had, in the first instance, been taken for the purpose, was for various reasons abandoned; a regular system of supervision was also organised; the different temporary hospitals or ambulances were annexed to the large military and civil hospitals; and the whole were arranged under ten great divisions, the number of beds inspected being 25,754, or in the ratio of about five per cent. of effectives, if we accept the strength at 475,000 men under arms within Paris.

It must be observed, however, that many of the wounded were, during the siege, treated in their own homes. The exigencies of the time, unfortunately, left little room for choice in the situation of buildings to be occupied by sick and wounded. Military requirements, as is often the case, superseded hygienic principles; and the result which frequently occurred must, therefore, in a great measure, be looked upon as inseparable from the conditions of a siege. No doubt great differences existed in the degree of suitability of the various buildings; some, and these by no means few, being altogether unsuited for the purpose. As a rule, the larger and more pretentious in appearance was the building, other than those originally instituted as hospitals, the less was its suitability for the purpose; the simpler the arrangement of apartments within, the more readily and satisfactorily was its transformation to its new purpose effected. Churches were, of all kinds of buildings, the most difficult to arrange as hospitals, and the least suitable for the purpose. Buildings, the inner apartments of which communicated directly or indirectly with each other, were unsuitable; and still more were those in which, in addition, a central passage separated opposite ranges of such apartments. In fact, the impression left upon the minds of many men of experience, as well as upon my own, was, that in no permanent buildings, whether originally erected as a hospital or not, were the chances of recovery among the wounded nearly so great as they were in huts, tents, and other temporary erections. This fact is, no doubt, important in itself, and is completely in accord with what has over and over again been said upon the same subject. There is one material consideration, however, which ought never to be passed over in connection with it; namely, that in a siege neither can huts be always obtained in sufficient numbers to meet all requirements, nor space be always available whereon to erect them, nor will workmen be disposable to saw the wood required and put them up when, as was the case in Paris, the male population are under arms. Here, then, is another important point in which hygiene and war are antagonistic to each other.

6. *Infirmiers.*—Under this general term I desire to include all attendants upon the sick and wounded other than surgeons and physicians; among them female attendants, whether as sisters, ladies, or paid women-nurses; as also male attendants or orderlies, whether gentlemen volunteers, members of religious bodies, untrained men hired for the occasion, or the regular *infirmiers*, such as were to be met with in the wards of hospitals, military and civil. I most willingly accord all praise and honour to the ladies, lay and religious, who devoted their time and labour upon the sick and wounded in Paris; yet I venture to remark that there are numerous circumstances in connection with a state of war which indicate very clearly the existence of an urgent necessity that military hospital organisation should be complete, and consist entirely of persons capable of withstanding the discomforts and fatigue inseparable from war. In this as in some other respects, it becomes necessary to guard against considering arrangements adopted or suitable during the siege of Paris as appropriate for the ordinary purposes of a campaign; for experience showed that in many respects they were not so. For military purposes, then, and for all departments connected with an army on active service, we require *men*. For the many duties connected with transport, care and attendance on the wounded, men trained, of good character and position, are quite as much needed as, and in several respects much more so than, in other positions connected with a force; and yet experience on the present occasion has confirmed what has been described in regard to other wars, that, neither in personal character, knowledge, or social standing, do the ordinary run of male *infirmiers* come up to the very important duties which often devolve upon them.

In my official report on my late mission, I enter more fully into the consideration of this matter than I can do here. I must, however, observe that the duty of attending upon the sick and wounded, if not an agreeable one, is one of vast importance, involving as it often does the issues of life and death; and that, therefore, so long as the life of an individual holds that importance to himself and to society which our civilisation accords to it, the necessity is paramount of obtaining the best security possible against its loss. This is indeed generally accepted in regard to surgeons and physicians; it is so in regard to trained female nurses; yet an equal necessity has not apparently been recognised in regard to *infirmiers*. Throughout the siege many circumstances indicated the great comfort enjoyed by the wounded, the attendants upon whom were well educated and intelligent men as contrasted with

those under *infirmiers* of the more common class. The success of surgical and medical treatment was more considerable in the one case than in the other, for the reason that the one class comprehended the importance of the duties which devolved upon them, and carried out with discretion the orders which they received, whereas the very opposite was the case in regard to the other. If, therefore, one lesson more than another was to be learnt from the experience of *infirmiers*, it pointed to the great importance of establishing for all hospitals, whether military or civil, a corps of steady, respectable, and tolerably well educated men as ward-attendants. Let sufficient inducement be offered, and we cannot doubt that men of the class alluded to will be obtained to enter upon the occupation as a regular business. In the words of a distinguished member of the French Intendance, "*Infirmiers*, as they at present exist, are a mistake; they are without interest in their cases; they are without discipline; they have imperfect knowledge. The system in regard to them must be altered."

7. *Societies under the Geneva Convention*.—Various societies under the "Red Cross" were formed in Paris in the early part of the Franco-Prussian war; and it is beyond question that they have been the means of conferring an immense amount of benefit upon the wounded in battle. Of those in Paris, the Société de Secours aux Blessés was the principal; next to it were those of the Press, the American, the Evangelical, etc. Some seventeen or more organisations of similar kind, but upon a smaller scale, were in operation.

In the month of August, 1870, the Société de Secours had despatched various ambulances to the front; the chief part of its operations, however, was confined to the capital. In order to indicate the large scale upon which its general operations were carried on throughout the war, I would transcribe the totals of *personnel* employed, maintained, and paid, by it. This included 16 principal surgeons, 58 surgeons, 101 assistant-surgeons, 139 subassistant-surgeons, 13 principal purveyors, 30 assistant-purveyors, 8 quartermasters, 40 chaplains, 29 *infirmiers* major, 48 corporal *infirmiers*, 546 *infirmiers*, 55 coachmen and drivers, 124 horses, and 40 carriages and waggons.

In the different hospitals working under or affiliated to the Société, the supplies of all kinds were liberal in quantity and excellent in quality; expense was altogether a matter of secondary consideration, the well-being of the sick or wounded being alone taken into account.

8. *Points of Surgical Interest*.—I scarcely know by what means to condense my remarks on this branch of my subject, so as to give on the present occasion even a bare epitome of a few of the most important points. Even in my official report, my observations were more brief than I could have desired, and now they must be still more curtailed. Considering the nature of the arms used in modern war, the character of wounds inflicted by their missiles proved an important object of inquiry; and, contrasting the injuries now seen with those observed in former campaigns, the following peculiarities of those sustained during the siege of Paris may be noted: 1. A large proportion of severe injuries in comparison to slight ones; 2. Frequency of multiple wounds in the same person; 3. The large number of wounds of the upper and lower extremities as compared with those of the trunk of the body (attributable, no doubt, to the increased penetrating power of modern arms and the increased mortality in the field of battle arising from wounds of the chest and abdomen); and 4. The absence of wounds caused by sword or bayonet. The occurrence of a state of "shock" after severe injuries, although in several instances manifest, did not appear to be by any means so numerous as it seemed to be among British soldiers in other wars—as, for example, the Indian mutiny; nor did the condition, when it did occur, command the degree of consideration described in works of the older surgeons of this country. The peculiarity may be attributable to "race", perhaps to other conditions, the investigation of which would have a scientific importance. As a rule, the dressing of wounded upon the field of battle was confined to merely what the urgency of individual cases required to allow the subject of injury to be conveyed in safety to the nearest hospital in the city. In a large proportion of instances, dressings of this nature were performed by the regimental medical officers of the French army under heavy fire—a fact which I take leave to mention specially in this place, as it has not, I think, hitherto obtained that degree of prominence which it deserves. A very large number of the wounded received their first dressings at the hands of surgeons working under the Red Cross; and it may be safely said that the whole of the transport of wounded, in so far as it was efficient or suitable, was performed by societies under the Geneva Convention. Three methods of treating wounds of the limbs appeared to be adopted in Paris. The first consisted in the use of apparatus and applications of the greatest possible simplicity; in the second they were more complicated, although in many respects extremely ingenious; in a third, the performance of a capital operation appeared to be a chief object in view. Each of these had its special recommendations. The two former were adopted in view

to the conservation of injured members; but, as we shall presently see, they were severally suitable only under particular conditions.

Among the methods under the second category, may be enumerated the *apneumatic* plan introduced and followed by M. Guérin. The author of the method having observed the rapidity with which union took place in cases of orthopaedic surgery, was first led to treat wounds communicating with the surface by the exclusion of *air*; he accordingly invented a pneumatic apparatus by which this object might be attained, and, as a result, the occurrence of suppuration prevented. The apparatus consists of India-rubber cases, forcing pumps and air-reservoirs, too complicated for description here; but as a detailed account of it by M. Guérin, containing illustrations, has been transmitted to Netley, full particulars will no doubt be given by some of the eminent professors of that establishment. Wounds of all degrees of severity, if on the limbs, were treated by its means, even to those of a grave nature penetrating the large joints, and with a large measure of success. What is deemed of most importance in this place in connection with it, is, however, the circumstance, stated to be a fact, that the patients thus treated by the exclusion of air escaped pyæmia, although that form of hospital disease prevailed extensively among the wounded treated according to ordinary methods in the same building. It is right to mention that considerable difference of opinion existed in Paris in regard to the efficiency or otherwise of the system as compared to the ordinary methods; the requisite apparatus is, moreover, so extensive and cumbersome as to be quite unsuited for employment in field army hospitals, but it deserves careful trial in stationary establishments; and with this view I solicit attention to it on the present occasion.

A large variety of applications in cases of wounds and operations were used by different surgeons. The various preparations of carbolic acid were extensively used, and no doubt advantageously so, inasmuch as its employment on patients in a ward seemed to greatly lessen, if, indeed, it did not altogether prevent, the occurrence of hospital disease. Solutions of permanganate of potass was used very effectively to foul wounds and to those extending far among the tissues, with or without fracture of the bones, or in which the missile remained imbedded. Nitric acid lotion was another excellent application under similar conditions; and among others used were tincture of arnica diluted, diluted alcohol, tincture of perchloride of iron, glycerine in various forms, simple and other cerates, and various disinfectant powders. In some ambulances, poultices were extensively used, but, in the greater number, fomentations, protected by oiled silk, were employed; drainage-tubes were used to an extent altogether beyond what we in England are accustomed to see; irrigation was in some few places used, but the arrangements necessary were inconvenient, and the process kept the bed of the patient and adjoining floor in an undesirable state of sloppiness. Bandages were, as a rule, applied with great neatness; but the quantity of cloth, charpie, and articles of dressing of various kinds beneath the bandages, not only confined the discharges in the wounds, but maintained an injurious degree of heat in the adjoining parts. Sponges were used far more extensively than they are in our war hospitals; and I cannot help thinking that considerable injury to the wounded in the mass occurred in consequence.

Oakum was first used in the American ambulance as a dressing for wounds, and as padding for limbs fractured by gunshot wounds; after a short time, its numerous advantages obtained for it extensive adoption in several other hospitals; these advantages consisting in its deodorising properties, in the readiness with which it absorbed offensive discharges, and in the excellent support which, by reason of its elasticity, it affords to injured limbs. The kind most generally used was the very coarsest; such, in fact, as is usually obtained under the name of "oakum"; and I am inclined to consider that, for the purposes indicated, it was superior to the finer descriptions of the same material.

A large variety of apparatus were employed for the support of limbs injured by gunshot wounds. Among the most convenient, the *Appareil Bonnet* deserves the first mention. It consists of a strong framework of iron bars well padded, and of a shape and size sufficient to accommodate both the lower limbs, and extend along the back to the shoulders, so that an injured person may lie comfortably in it, the wounded limb secured and padded as may be necessary, and the apparatus itself so arranged by a mechanist as to admit of dressings being readily applied wherever needed. The anterior suspended iron splint, first introduced by Dr. Smith, and improved by Dr. Shrimpton, had a somewhat extensive trial in the Ambulance du Corps Législatif. It was found useful in some cases of wounds of the lower extremity, but requires much time and labour to ensure its proper application. Gypsum cases placed over suitably arranged splints, or padded so as to avoid pressure upon subjacent parts, were also used, and very successfully; motion in cases of compound fractures being by this means completely prevented; and, lastly, no other support was in some cases applied to wounded in-

senior limbs than carefully laying the member upon and between properly protected cushions, it being kept in position merely by means of a triangular piece of wood of suitable length placed under the pad on either side. In all these cases, means were of course taken to ensure the absorption of discharges by means of suitable dressings to the wound itself.

The terrible extent to which hospital disease prevailed in the hospitals and ambulances during the siege of Paris is now well known. At the time, it furnished one of the principal causes of anxiety to the surgeons, producing a great part of the mortality which prevailed among the wounded and those subjected to operations. Several conditions combined to produce the various forms in which these affections manifested themselves. As already observed, some of the buildings occupied by the wounded were altogether unsuited for the purpose. Others were overcrowded, others insufficiently ventilated; in some, ventilation was chiefly from one occupied room to another—as, for example, the Grand Hotel; while in others, a central passage received the emanations from the wards on each side of it, but was itself without the means of complete perfusion. It is to be feared that, in some of the hospitals, soiled clothing and bedding were not removed from the rooms occupied by the wounded as quickly as was desirable, and that this defect in sanitary arrangements was altogether beyond the power of the surgeons to remedy. In addition to all these conditions, many of the men had suffered from insufficiency of food for a lengthened time before receiving their injuries, and while under hospital treatment were, from a stress of circumstances, unable to be provided with the amount of nourishment in food and wine that their condition actually needed. In fact, it may be questioned if the same liberal scale of diet and “comforts” which is allowed in ours, is ever given in French hospitals. We give plenty of beef and porter; they give “Vin de Bordeaux” and a little “confiture.”

On taking into account the different kinds of treatment followed for gunshot injuries, the different conditions under which wounded in Paris were placed, and the different results which followed injuries of similar degrees of severity, the importance presented itself of devising certain rules by which treatment under such varying circumstances should be followed. This important point received the attention of many of the eminent men who bestowed their services in the great emergency of the siege; but the result did not indicate more than an approximate arrival at the desired conclusions. These conclusions seemed to be that, as regards amputation, that operation was more suited than excision or resection when its subject had to be carried on with an army; that excision and resection was much more likely to be successful when practised in the upper than the lower extremity; that excision of the knee as a substitute for amputation in cases of gunshot wounds of that articulation, has sadly failed, although it has succeeded in cases of disease occurring in civil life.

The practice of conservative surgery has also proved itself to require the application of definite rules, even in stationary hospitals provided with extensive apparatus, mechanism of all kinds, trained and intelligent attendants, and so on; and its success under such circumstances furnishes no criterion of its suitability in movable hospitals with an active army. Its requirements involve very great attention and physical fatigue on the part of the surgeons; such, indeed, as can alone be fully carried out when there are comparatively few cases of considerable severity to be attended to; there is always great risk of the patient suffering from some form of hospital-disease, and in many cases the limbs saved are of relatively little use. There are exceptions to this, but such is the rule. In tents and huts, patients thus treated have undoubtedly a better chance of recovery than those in houses; but even in them the risk of hospital-disease is by no means absent.

These notes represent very imperfectly some of the valuable professional lessons which were to be learnt in Paris during the siege, and contain no more than a bare summary of some of the subjects, on the consideration of which I have entered more at length in the official report which I have had the honour to submit to the authorities. In that report, I have availed myself of the opportunity afforded to acknowledge the great amount of consideration and personal kindness, which I received from members of the profession and others with whom I came into contact in the course of the important events connected with the Siege of Paris, and have mentioned by name those to whom I am in more especial manner indebted. I believe that the courtesy shown me by the members of the medical profession in Paris was, in my person and that of my coadjutor, shown to the profession in this country. In this spirit we received it; and in this spirit I now allude to the circumstance, believing, as I do, that whatever rivalries may unfortunately happen to interrupt the good understanding of nations, we of the medical profession have no rivalry with our brethren of other countries, other than that of a desire to advance our science and extend its benefits for the good of the masses.

## ABSTRACT OF A CLINICAL LECTURE ON VARICOCELE AND ITS TREATMENT.

*Delivered at King's College Hospital, June 9th, 1871.*

By JOHN WOOD, F.R.S.,

Surgeon to the Hospital, and Professor of Surgery in King's College.

GENTLEMEN,—We have had lately in the Hospital many cases of *varicocele*, and you have had the opportunity of comparing several methods of treatment which have been followed. In its general pathology, *varicocele* resembles the diseased conditions of the veins which are found in other parts of the body, and known by the name of *varix*, and the common forms of *hæmorrhoids* or piles. In all these, the coats of the veins are the seat of the disease, which consists essentially in dilatation of their calibre and hypertrophy of their walls, with consequent loss of the function of the valves, which aid circulation of the blood through them. But in each of these different regions of the body where *varix* is found, there are peculiarities which modify the pathological cause, and require peculiarities of treatment to meet their several exigencies. In true *varicocele*, the veins of the spermatic cord which convey the blood from the testicle are the vessels solely affected; and it must not be confounded with *varix* of the superficial veins of the scrotum, which occasionally occurs. The circulation of the blood through the testicle is probably normally slow, corresponding by the intricacy of its channels with the very tortuous and complex system of tubes which elaborate and transmit the secretion when formed. The return of the blood through the spermatic veins is retarded (1) by the intervention of an elaborate plexus, the *plexus pampiniformis*; (2) by their passage through the fibrous inguinal rings and canal, and the muscular cremaster and internal oblique, which closely invest the cord as it hangs over Poupart's ligament; and (3) by the length of the column of blood within them, reaching from the testis to the renal or caval veins high up in the abdomen.

Now, in a perfectly normal condition, the elastic resiliency of the coats of these veins is such that the retardation is effectively controlled and modified.

But slight imperfections are extremely common, and are evidenced in most individuals as an increase in the size of the left spermatic cord. In the surgery of the schools, this is commonly attributed to the fact of the left testicle being placed lower in the scrotum than the right, and to the opening of the left spermatic into the renal vein at right angles to the current of blood in the latter, and not, as on the right side, at an acute angle, with a course more parallel to the current in the inferior cava, and more adapted to the efficiency of the valve-action at the acute side of the angle. But a difference in length of column of about half or three quarters of an inch, or in the angle of junction to the extent of a right angle, do not, in normal conditions and in other situations (where they are common enough), produce undue dilatation of the veins. The other predisposing cause commonly assigned for this greater frequency on the left side, is, in my opinion, a much more powerful one; and that is the position of the sigmoid flexure of the colon across the front of the left spermatic plexus. The sigmoid flexure is the temporary receptacle of the fully formed fecal mass, until the habitual or convenient time for its expulsion has arrived. In civilised society, there are frequent and unavoidable conventional causes for delay or neglect of Nature's indications; and constipation and consolidation of the feces is a common accompaniment of artificial modes of living. We have thus greater habitual pressure upon the left spermatic plexus.

But along with these predisposing causes must coexist some other condition lying in the coats of the veins themselves, otherwise the same anatomical, mechanical, and conventional causes would operate alike in all individuals, which is notoriously not the case. Now, in a healthy vein, the middle coat is found under the microscope to contain abundantly muscular fibres of the same kind as those in the arteries. They are arranged both longitudinally and circularly in several successive layers, intermixed freely with white connective tissue, and with a smaller proportion of elastic fibres. In the larger veins, of the abdomen especially, the outer coat also contains, according to Remak, a considerable proportion of non-striated muscular fibres; and this peculiarity extends to a great extent into the spermatic veins. The veins of the lower extremity have thicker coats than those of the upper, and the superficial veins thicker than the deep ones.

If you take a portion of the coats of a vein in a varicose condition,

and place it under the microscope, you will find that the hypertrophy depends chiefly upon the development of white connective tissue in the outer coat, while the muscular and elastic fibres are proportionately much less developed. The mechanical stress upon the vessels has promoted the development of the merely resisting material, and has atrophied by over-tension the contractile and resilient elements. In some cases, also, I have found a certain amount of amyloid or fatty degeneration of the muscular fibres. At a certain point of the lateral distension, the valves cease to be effective in closing up the tube against regurgitation, and they become finally shrivelled and atrophied from disuse. This promotes the stasis and accumulation of the blood within the vessel, and, longitudinal hypertrophy commencing, results in the coils and serpentine folds which are so characteristic of an advanced stage of varicose veins. We have, in fact, in varicose veins, a condition, *mutatis mutandis*, resembling, in the thickening of the outer coat and the diseased condition of the middle coat, that of true aneurism in the arteries. There can be no doubt that this predisposition of the venous system is, like so many other diseases, the result of hereditary transmission.

Into the various points of the differential diagnosis of varicocele, I have scarcely time on this occasion to enter. I may, however, mention that the condition which is most difficult to distinguish from varicocele is the presence, in a narrow hernial sac, of an elongated portion of irreducible or adherent omentum, dragged out in the curious and perplexing way in which we sometimes see it, simulating a thickened spermatic cord, or a cyst, or even a testicle, almost perfect in shape. The most certain way of distinguishing them is to mark the effects of position in the recumbent posture, maintained for a length of time sufficient to empty the varicose vessels. Upon an adherent omentum, this has, of course, little or no effect. But the coats of varicose veins are occasionally so thick in themselves that a considerable tumefaction remains, even after the blood has passed almost entirely out of them. In such cases, the only resource is in the *tactus eruditus*, which cannot be conveyed by words—the peculiar centrifugal dilating impulse which the cough impresses upon the varicocele, and which is different from the communicated impulse of an omental hernia. When the omental hernia is reducible, no difficulty should arise. The means of distinction given in books is to reduce the swelling while the patient is in a recumbent posture, and then placing the finger firmly upon the superficial ring, to let the patient assume the erect posture. If it be a hernia, the swelling does not return; but if it be a varicocele, it does so in a short time, but gradually. Fatty developments in the cord are usually persistent under any position; and, like omental hernia, doughy and inelastic to the feel, and, unless confined to so high a position in the inguinal canal as to contraindicate varicocele entirely, have not usually a cough-impulse.

Varicocele is often attended by an amount of pain totally disproportionate to the size of the tumour. It is probable that this proceeds from pressure or tension, during the initiative stages of the disease, upon the spermatic plexus which surrounds and embraces the veins, and supplies branches to their coats. The pain usually affects, also, the groin of the same side, and sometimes reaches the lumbar region, by an effect upon the renal plexus, from which part of the spermatic plexus is derived.

In many cases, also, there is a morbid fixity of the attention of the patient to his condition, which is sometimes indicative of serious mental derangement. Atrophy of the testicle may be coexistent with varicocele, and in most cases is the result of the impaired nutrition consequent upon the continued congestion which results from the varicocele, as in the condition called varicose eczema in the legs. In most cases, an operation, if applied early enough, will prevent this atrophy; but sometimes the wasting goes on, and may even be considered by the patient as the effect of the operation. He should always, therefore, be informed beforehand of this possible result.

The treatment that you have seen lately carried out by me, gentlemen, is an application of the principle of metallic wire-pressure, applied subcutaneously, and with very little disturbance of the parts, by means of a new instrument which I have devised and carried out, with the help of Mr. Matthews, for the application of a continually acting spring traction. The very ingenious apparatus of M. Ricord was previously the most successful attempt to effect the same results; but it acted upon a silk or hempen ligature, applied in a peculiar manner round the vein, and had not the advantages of metallic pressure. This apparatus is ponderous, unwieldy, and requires screwing up afterwards. I have made many attempts, gentlemen, as you know, to obtain the advantages of continuous and unintermitting wire-pressure, so applied and self-acting that no subsequent interference by the surgeon or any screwing up of the apparatus, should put the patient to all or more of the pain of repeating again and again the original operation; so arranged that the wire could be at any time disengaged and removed with little or no pain to the patient, or disturbance of the parts; and so simple as to be easily managed by anybody, easily cleaned, and not liable to get out of

gear. Well, the outcome of so many trials seems simple enough when you look at it, as did the celebrated egg-trick of Columbus. It is a strong, steel, highly tempered spring, acting like the spring of a pair of dissecting forceps. One limb carries at the end a thin round steel shaft,

about an inch and a half long, which ends in a transversely oval and obliquely placed eye, for transmitting the wire snare or loop which encircles the vein. The other limb terminates in an arm or hook, round which the ends of the wire are twisted and fastened. The rings upon the two arms are for the purpose of giving a firm hold to the finger and thumb while compressing and closing the spring (as shown at the middle of the figure), till the ends of the wire are fastened upon the upper limb. The dotted lines at the outer part of the figure show the upper arm when at the extent of its action; and its distance from the closed arm shows the extent of transit of the wire to be more than is necessary to drag it clean through the enclosed vein. The steel shaft which carries the wire is pressed down close upon the vein through the puncture, at which the ends of the wire emerge. The puncture is left uncovered for the escape of any discharge which may form, for which the shaft of the instrument and the wire form a direct conductor. I have found it better, also, so to arrange the punctures that the one through which the instrument passes shall be the most depending point in the track of the wire, so that no accumulation of discharge is possible within the wound. This is a point of much importance to obviate any subsequent trouble. It is also important, as I have proved experimentally, to provide that no pressure or obstruction be placed at the puncture through which the wire emerges; but that allowance be made for any swelling of the parts around which may occur. This is effectively provided for by the length of the steel shaft, and the elevation of the counterpressure from the surface of the wound. Any instrument which covers over, obstructs, and presses upon the puncture in the skin, is objectionable for this reason. In large cases, of course, a larger instrument and a stronger spring may be required. In small cases, a spring of twisted steel wire, somewhat like that of a mousetrap, has been found sufficient. Such an instrument I have found to act admirably in cases of varicose saphena.

The wire used is the best and toughest iron wire, as thin as may be judged strong enough to bear the tension of the spring. It is first dipped in carbolic oil, and passed by means of a long needle in the ordinary subcutaneous way, first under the veins, and then back again over the veins, between them and the skin, entering, re-entering, and emerging through the same cutaneous apertures. The ends are then drawn as taut as possible; the loop sinks through its puncture into the tissues out of sight; and the spring-tractor is finally fixed by passing both ends of the wire through the oval eye, pressing down the spring firmly between the left thumb and forefinger, winding the wire tightly round the hook, and fixing it there.

In most of the cases lately in the hospital, all of them men under the age of forty years, the spring-tractor was kept on for a week or ten days; but in one case, which is now in hospital under treatment, we had to deal with a very large varicocele, reaching down behind and below the testicle. In this instance, a pair of tractors and wire ligatures were applied, one above, and the other below and behind the testicle, and kept on for fourteen days. In none of these cases have the patients complained of any pain worth speaking of; there has been little or no discharge, and no formation of pus; and they have been discharged cured a few days after the removal of the wires. In the last-mentioned case, some time after the instruments and wires were withdrawn, we had a very small superficial abscess, but it occurred in a different part of the scrotum, towards the opposite side, and resulted, apparently, from the pressure of the cross strapping used to sustain the scrotum. It was opened by the house-surgeon, and gave thenceforth no more trouble.

In all the cases, we have had a very great amount of thickening from fibroid deposit in the track of the wire ligature, producing a great amount of lateral support to the weakened vessels, and persistent for a considerable time, as you may have seen by the patients who have returned for inspection, at a period of many months subsequent to their discharge from the hospital. In patients whom I have seen years after a precisely similar operation, effected by means of an instrument acting with wire in the same manner, but upon a different principle, which I then employed, the veins have remained quite impervious, with a hard, firm, constricted portion, or indurated ring, at the site of the operation. In most of the cases, I have withdrawn the wire before it has quite cut through all the included tissues, and the results have been equally good as in those in which the loop has cut its way clean through. I believe, therefore, that it is not always necessary to prolong the cure by waiting for this result, inasmuch as a great deal of fibrous tissue, not forming part of the venous channels, is necessarily included in the ligature, and often prolongs the process of separation after the veins have been entirely occluded. A dense, hard, and resisting ring of fibroid tissue is formed around the veins by the action of the ligature, which resists the pressure of the blood outwards, and prevents redistension. And not the least of the advantages of the apparatus I have described is the power that it gives us of withdrawing the ligature without pain or disturbance, when it is evident that the desired result has been arrived at, as ascertained by the deposit of fibrine and the small length of the wire yet remaining engaged in the tissues.

In this method, gentlemen, it appears to me that we have all the advantages of subcutaneous treatment and thin metallic pressure, combined with a continuous and equable traction, by which we obtain a division of the diseased veins without danger of hæmorrhage, with little or no pain to the patient, without the repetition of a most excruciating process of tightening or screwing up the ligature upon the inflamed tissues; and we get, in a short course of treatment, complete division or occlusion of the veins, no open sore (which, in such cases, is very often very slow to heal), and no suppuration which may endanger the entrance of pus into the veins. And this is combined with the power of disengaging the wire compress; with little pain and no disturbance of the parts, which might set up the process of disintegration of the clot or suppuration of the vein; and with a simplicity of construction and ease of manipulation which leaves little to be desired in the way of improvement.

## THE PROVISION OF MEDICAL ATTENDANCE ON THE INDEPENDENT POOR BY PROVIDENT DISPENSARIES.\*

By C. B. NANKIVELL, M.D., Torquay.

MR. PRESIDENT AND GENTLEMEN,—It may perhaps be thought that the subject which I am about to bring before your notice is not altogether appropriate to this Section of the Association, which has for its more especial object the prevention rather than the cure of disease. But if we consider the very large number of poor persons placed between the class of paupers on the one hand, and those capable of procuring medical advice for themselves on the other; and if we further reflect how entirely these poor people rely on their daily labour for the supply of all the necessities of life, and how much their ability to labour, and consequent means of subsistence, depend on their maintenance of health; we shall at once see how necessary it is for the early arrest, if not for the prevention, of disease, that this large class of the population should have placed within its reach prompt and efficient medical attendance.

Early medical advice in the diseases of the poor is likewise most important, in a sanitary point of view, to the whole community; for it is in the crowded habitations of the most crowded parts of large towns, occupied, as they are, by their most indigent inhabitants, that severe and fatal epidemics usually make their first appearance, and from these localities they extend to other classes of society. On these grounds, it may surely be considered that all associations and institutions which bring ready medical help to those who cannot individually command it for themselves, are essentially of an hygienic character. Their claims on the ground of benevolence, and their importance as a part of sound

political economy, need not be enforced before a meeting of the British Medical Association.

If, then, the preservation of health and the prevention and early cure of disease amongst this class of the industrious poor is so serious and desirable an object, it becomes a question of great moment to ascertain by what means, and to what extent, and with what effect, this object is at present accomplished. The result of this inquiry is already known to the members of this Association. It is well known to be unsatisfactory in the extreme. It is notorious that the system of gratuitous medical charity—the prevailing system in this country—is very defective in its operation, and fraught with evils of great magnitude. There can be no doubt whatever of the great benefits conferred upon the poor by hospitals in various parts of the United Kingdom. These valuable institutions afford to the poorest man the highest medical skill, constant medical supervision, and all the comforts and appliances in sickness which even the most affluent can scarcely more fully obtain. But when we come to the out-patient department of these establishments, and their allies in the same mode of medical provision—the dispensaries existing in all large towns—we find a lamentable deficiency and many faults in carrying out their intentions.

It has been clearly pointed out by Dr. Heslop of Birmingham, and by many others, that the ordinary support of medical charities by privileged subscribers is a financial and sanitary failure. It must, almost of necessity, be inadequate to the purposes for which these institutions were designed, for it is found that the supply of gratuitous medical charity invariably increases its demand. In Manchester, as shown by Sir James Kay Shuttleworth many years ago, the increase of medical charities augmented, in six years, the recipients of such charity from one-eleventh to one-seventh of the population. In Liverpool, Leeds, Birmingham, and other large towns, similar results have been observed. In the course of time the supply becomes unequal to the demand, and many of the suffering expectants of relief are doomed to disappointment, and at a time, perhaps, when such relief is most urgently required. The supply, too, of this charitable bounty, almost always attended with some delay and loss of time to those who seek it, is generally fitful and intermittent, profuse when tickets of recommendation are first given out to the subscribers, scarce, and perhaps exhausted, a few weeks afterwards; and it seems to be everywhere complained, that these recommendations are seldom given to those by whom they are most needed, but to the *protégés*, the servants, and adherents of the subscribers, or to the most active applicants who go about in search of them. And whilst these institutions, so constituted, fail in the supply of prompt and certain medical aid to the great bulk of the proper objects of medical charity, they, and all other modes of gratuitous advice to out-patients, are often attended with much hardship and injustice to the members of our profession. Their unpaid and overworked medical officers are, in many instances, placed in the invidious alternative of wasting much valuable time in attending on trivial and unimportant cases, or of adopting a hasty and routine practice, far from beneficial to the patients or advantageous to medical science, and most mischievous in medical teaching.

A large number also of the out-patients are quite above the necessity of any charitable assistance, and are well able, either separately and individually, or conjointly and by co-operation, to procure medical attendance for themselves. So great injury is done in this way to many struggling medical men, and to the younger members of the profession, that they avoid the neighbourhood of large institutions of this kind as being barren and unprofitable ground. Great, however, as these evils are, physically to the poor, and as opposed to the just interests of the profession, they are trifling in comparison with the injury caused to the working classes by the demoralisation which always attends the profuse and injudicious administration of gratuitous medical charities. This is one of the consequences of these institutions which has not yet been sufficiently brought before the public. Their supporters seem to assume that, as the necessities of sickness are not amongst the daily natural wants of mankind, no care or forethought can be expected on the part of the poor in providing against them. No fallacy in social science can be greater or more mischievous than this. It was shown many years ago, and of late years it has been still more clearly proved, that sickness and various moral causes are the most fertile sources of pauperism. Dr. Wallis and Dr. Rogers have estimated sickness, as at present unprovided for, at 72 per cent. among the causes of this, the lowest grade of poverty. The industrious working man, as long as he is in good health, is generally independent of all extraneous aid. It is only when illness, unprovided for, assails him, that he is led to seek the help of charity in the form of gratuitous medical attendance. He thus takes the first step towards reliance on others instead of on his own exertions. The necessity of frugality, forethought, self-reliance, and self-provision is sapped and undermined; and the gate of eleemosynary assistance having been opened by the reception of medical charity, he is allured to become a

\* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

mendicant to other charitable institutions, and is ultimately driven, by his loss of industry and spirit of independence, and the attendant vices of such a state, to the dire necessity of parochial relief. It is scarcely possible to overestimate the injury—the moral and physical degeneration—thus thoughtlessly inflicted on that large stratum of society between the pauper and those capable of individually supplying their own material wants.

It is true that the industrious classes have themselves made most laudable efforts to meet all the exigencies of sickness amongst a limited number of their class, by the establishment of sick clubs; and most valuable have been some of the results of these societies; but their provision for medical attendance has the defect of excluding the women and children of their families, and it has almost invariably been found that these self-supported and self-managed associations beat down the terms of contract with their medical officers to the lowest possible point, whilst they admit amongst their members, without any limit or restriction, many who, from their pecuniary circumstances, should be included in the lists of the private patients of the medical men in their neighbourhood. It is obvious that no department of any society deserves encouragement, which is so unjust to the members of a profession whose generous and philanthropic instincts and traditions have long placed them in the van of every measure which has had for its objects the health and welfare of the public.

Having now described, as briefly as possible, some of the faults and sad consequences of the present provision for medical attendance on the unpauperised poor, it becomes my more agreeable duty to direct your attention to what appears to be the best means of reforming this department of Public Medicine.

In 1829, I became acquainted with Mr. Smith, of Southam, and spent the following winter and spring under his roof, in professional attendance on the patients of his self-supporting dispensary, and of a small hospital which he had established at Southam, also on the plan of partial self-support. To Mr. Smith is due all the credit of first applying the provident principle to this form of medical charity, to the promotion of which he zealously devoted himself by institutions under the title of self-supporting charitable and parochial dispensaries, including an admission of the three classes of patients which this title indicates. During my abode at Southam, I visited all the places in the Midland Counties at which these dispensaries had been established, with a view to ascertain the several causes of their success or failure. On my return, it was agreed by Mr. Smith and myself that it would be better to limit all future efforts to the promotion of the provident principle only; and we drew up some rules for the first dispensary thus formed at Burton-on-Trent.

In 1831, I was urged to settle at Coventry, as the medical officer of a dispensary about to be established there, for the purpose of carrying out the principle of which I had become a warm advocate. I was anxious that the Coventry Provident Dispensary, as I suggested its being called, should serve as a model for dispensaries in other places which might follow our example. We therefore conducted it tentatively for the first two years before finally deciding on its constitution and code of laws; and I can now congratulate those who cordially acted with me on that occasion, that these laws have formed the plan of all subsequent successful institutions of the kind. The Coventry Provident Dispensary still prospers. It has about five thousand free members, from whom it annually receives about £800, and pays to its three acting medical officers about £180 a year each. I mention these facts to show that I am not advocating this system on mere speculative theory, but on the ground of experience and practical knowledge of its successful operation during many years.

The Derby Provident Dispensary, which in 1844 commenced the exclusion of all but provident patients, had, at its last report, more than five thousand free members, from whom it received nearly £1,000 during the year.

The Provident Dispensary at Northampton, a smaller town than Derby or Coventry, received last year from its free members, paying the same rate of subscription as at Coventry and Derby, the extraordinary sum of £1,881, and divided amongst its three medical officers £1,503. The reason of the greater number of free members and larger amount of receipts at Northampton is obvious and instructive. In Northampton, the working-classes have not been demoralised by gratuitous medical charity. Its noble county hospital, though near the town, does not give medical attendance to out-patients at their own homes.

Besides these, there are more than twenty other provident dispensaries, all more or less successful, existing in several parts of England; and here, at Devonport, we have a most satisfactory example of the application of the provident principle to the out-patient department of the Royal Albert Hospital. It seems satisfactory in every respect, except that it applies too large a portion of the free members' payments to the

expenses of the hospital, and gives too little to the medical officers for their work amongst the out-patients.

The success of these several institutions shows how much may be done by the poor to help themselves and to help one another, with a little encouragement and assistance from their more educated and richer neighbours; and the remarkable success of the Northampton Dispensary especially proves how much more may be done, where the working classes have not been spoilt and degenerated by habits of reliance on eleemosynary assistance. Surely, too, from these examples, we may hope and infer that, by a careful and wise co-operation between our profession and the enlightened benevolence of the truly charitable, it would not be difficult to supersede the necessity of entirely gratuitous medical charity, except in the general hospitals of the country. A firm combination of the profession and the public would thus at once bring about a most complete and judicious "reform of out-patient administration."

The effect of such a change of system would be an immense advantage to the poor, whilst it would conduce to the honour and interests of our profession. To every poor man and his family, between the pauper and those capable of paying individually for medical advice, it would offer and supply an easy provision of prompt and efficient medical attendance; prompt, because the small payments of the free member of a provident dispensary would entitle him to medical advice whenever he required it; and efficient, for the Committee would take care that its medical officers were qualified members of the profession. To the medical profession it would hold out an honourable office, in which the duties of the officers would not be the less zealously performed because the value of their services was acknowledged by some pecuniary remuneration. I feel also assured that all the members of my profession would eventually rejoice in the adoption of a system which, instead of humiliating and lowering the character of their poorer patients, would tend to raise them in their social position and moral tone.

In the construction of provident dispensaries, there are some conditions essential to their success, which those who wish to establish them should carefully observe. And I am the more especially anxious to direct your attention to these fundamental conditions, because I have invariably found that it has been the neglect of or departure from them, which has caused the failure of several endeavours to establish institutions of this kind. To bring these leading conditions before your notice has, indeed, been my principal object in writing this paper. As an essential principle, it should always be borne in mind that for the success of this system it must invariably be in accordance with the wants and welfare of the working classes, and with the interests of the members of the medical profession, who form its active and indispensable agents. If conducive to the just interests of both these parties, it can scarcely fail of success.

In the first place, a sufficient contribution should be raised amongst honorary donors and subscribers to pay for the outfit of the dispensary. This sum would vary with the probable number of patients. An adequate annual subscription from honorary subscribers should also be calculated upon, to meet all the expenses of the establishment above the cost of medicine and the payment for medical attendance. This annual sum required would of course also vary with circumstances, but would be less than in an eleemosynary dispensary, on account of the cost of medicines being chiefly defrayed from the payments of the free members.

The free members' weekly payments should be as small as possible, to prevent the exclusion of any poor person above the actual position of a pauper. A penny a week from all adults, and half that amount for each child under the age of remunerative labour, allowing all beyond a certain number of children to be admitted free of payment, are generally found sufficient.

From the sum thus raised from these benefiting members, a certain proportion should be deducted towards, but not more than sufficient to defray, the cost of medicine. The rest should be divided amongst the acting medical officers. The patient thus has the satisfaction of paying for his medicine and medical attendance; and the medical officers are exempted from any direct interest in the quantity or quality of the medicines which they prescribe.

On the admission of a member, and periodically afterwards, he should have the choice of enrolling himself as a patient of the medical officer he may wish to attend him when required; and the payments to the medical officers should be in proportion to the numbers enrolled on their respective lists.

The number of the medical attendants of a provident dispensary should be proportionate to the number of members. One medical officer to every thousand members would probably be a desirable proportion; and, to prevent unfair monopoly in the district of the institution, the appointment of the medical officers should be periodically re-

newed, and reappointments should not take place if there were other eligible and desirable candidates. Periods of five years, as adopted in the Provident Dispensary at Leamington, would probably be found expedient. To protect the interests of the dispensary and the profession from the admission of ineligible free members, it is important that the medical officers should be *ex-officio* members of the Committee.

I have a very strong conviction that it is an indispensable element of success in these institutions, that their control and government should be in the hands of the honorary subscribers. I should be extremely sorry to see provident dispensaries lapse into the form and state of sick clubs, with a spirit of antagonism between the medical officers and their managing patients, and power in the hands of the latter of advertising for medical attendants on the lowest terms; and also with the power of admitting amongst the benefiting members and patients a wealthier class, whose admission might be desirable for the club, but very adverse to the just interests of the profession.

I have seen, with much regret, that my friends at Coventry, on the fortieth anniversary of their Dispensary, as the first material alteration of their original laws, have decided to admit every adult free member to equal rights of government in the Institution with the honorary subscribers. Thus, as the honorary subscribers are not more than forty, whilst the free members amount to several thousands, they have obviously placed the property and government of the Dispensary in the power of the benefited members. They have also, but perhaps unintentionally, adopted the advanced form of government by universal suffrage, with female franchise and vote by ballot. I have great confidence in the governors and free members of the Coventry Dispensary; and as the Committee is fairly formed, I have great hope that the Institution may not suffer from this dangerous experiment, and be left, as suggested by some of the advocates of this change in the plan of provident dispensaries, to the entire support and management of the poor members.

It is surely most important, in the effort now so widely making to extend the system of these dispensaries, not to lose sight of the leading principles and conditions upon which they have been successfully conducted for nearly forty years. It is certainly desirable to see the intelligent and well-conducted of the working classes actively assist in promoting all social measures for their own benefit; but it should be remembered that the object of these dispensaries is not to aid the skilled artisan and higher class of workmen, receiving rewards of their labour adequate to the supply of all their own wants, but to meet a great necessity of a poorer class, some of them, perhaps, on the verge of pauperism, and to prevent their sinking still lower in the scale of poverty. Surely it is not desirable or judicious to leave the support of institutions for such objects to the hard-working poor themselves. Is it not rather a duty, and for the welfare of all classes, that the more affluent should apply a portion of their means, their time, their cultivated intelligence, and their trained and judicious benevolence, to objects of this kind in aid of their poorer neighbours?

I cannot conclude these very incomplete observations on the important effects which would accrue from the general adoption of provident dispensaries without alluding to the advantages which they might supply in the present mode of medical education. We hear continually, not only amongst intelligent and experienced members of the profession, but amongst medical students as well, very general complaints that the annihilation of apprenticeships has deprived the student of the present day of the opportunities which his predecessor enjoyed of acquiring the fact and practical aptitude so necessary in the practice of the profession. I know of no public means which could be so easily and well adapted to this purpose as a dispensary or out-patient department of a hospital conducted on this system, under the direction of skilled medical officers. The advanced student would thus be introduced to the observation and treatment of disease in the way he would have to meet it in after practice; and, from the permanent association of the patient with the institution, he would see every variety of disease at its commencement, throughout its whole course, to its termination, and under any sequelæ or recurrence of the malady which had been brought under his notice. Nor would the medical officers find this kind of attendance troublesome and oppressive. The poor patient who has had the forethought and prudence to provide himself with medical advice is generally grateful for the benefits he receives, and thoughtful for those who confer them.

Since my thirteen years passed at Coventry, I have lived under brighter skies, and in a more picturesque part of my own country; but I still look back to the lessons then employed, not only as the most useful, but as amongst the most agreeable of my life.\*

## AN ANALYSIS OF STATISTICS OF LATERAL LITHOTOMY.\*

By the late WILLIAM KEITH, M.D., M.R.C.S.E.,

Senior Surgeon to the Royal Infirmary, Aberdeen;  
Lecturer on Clinical Surgery; etc.

[BETWEEN the time when Dr. Keith published his previous paper on this subject and his death, he operated on *thirteen* additional cases by lithotomy, thus raising the total number to 221. Of these last 13 cases, *two* died, making the total number of deaths 45, or a total mortality of 1 in 4.91 or 20.36 per cent.

The principal details of the last thirteen cases may be given, in order to complete the former detailed statistical account.

Case 209, aged 4½ years; weight of stone, 3½ drachms; dismissed cured 29 days after operation.

Case 210, aged 59 years; weight of stone, 7 drachms; dismissed cured 51 days after operation.

Case 211, aged 64 years; weight of stone, 5 drachms; dismissed cured 73 days after operation.

Case 212, aged 8 years; weight of stone, 4 drachms; dismissed cured 26 days after operation.

Case 213, aged 53 years; weight of stone, 3½ drachms; dismissed cured 51 days after operation.

Case 214, aged 63 years; weight of stone, 1½ ounces; dismissed cured 36 days after operation.

Case 215, aged 65 years; weight of stone, 1 ounce 4½ drachms; dismissed cured 35 days after operation.

Case 216, aged 67 years; weight of stone, 1 ounce; died 11 days after operation.

Case 217, aged 51 years; 5 stones: gross weight, 1 ounce 7 drachms; dismissed cured 27 days after operation.

Case 218, aged 55 years; 2 stones: gross weight, 1 ounce 4½ drachms; dismissed cured 31 days after operation.

Case 219, aged 78 years; weight of stone, (?) ; died 2 days after operation.

Case 220, aged 63 years; weight of stone, (?) ; dismissed cured 26 days after operation.

Case 221, aged 70 years; weight of stone, (?) ; dismissed cured.

The following account of the fatal cases was drawn up and revised by Dr. Keith a considerable time previous to his death, and is given in the state in which it was left by him.]

### Notes of Cases of Lithotomy in which Death followed.

As we and others often derive most instruction from our failures, I shall, therefore, briefly give the leading points connected with the fatal cases in my lithotomy experience.

CASE V.—Alexander Allan, aged 74, a farmer, was admitted into the Aberdeen Infirmary on October 24th, 1839, suffering from the usual symptoms of stone in the bladder. A calculus having been detected after he had been in the house for a time, he was operated on, November 20th, and a stone, weighing 1 ounce 3 drachms, and measuring 2 inches by 1 inch by 1½ inches, was removed. He continued quite well, with a pulse not above 80, and urine flowing freely, till late on the evening of the 22nd, when he got out of bed and sat up for two hours. In dancing to show how well he was, the tube escaped from the wound, and the night-nurse, in trying to introduce it, inflicted such injury that fatal inflammation resulted, and he died on the 23rd, three days after the operation. *Post mortem* examination revealed the fact that the nurse had thrust the tube up between the pubes and bladder, allowing urinary infiltration into the abdomen; the man dying from extensive peritonitis, the evidence of which was manifest throughout the abdomen.

CASE XIV.—William Kennedy, aged 4, was admitted on the 8th February, 1842, and operated on the 5th March, when a stone, weighing 1 ounce 14 drachms, and measuring 1½ inches by 1 inch by 1½ inches, was removed, as was also a second small calculus. He went on well enough till the evening of the 6th, when he complained of pain in his belly. Six leeches were applied over the region of the bladder; and the night-nurse stupidly encouraged the bleeding all night by hot poultices, so that he lost a great quantity of blood. He never rallied from

\* We have to acknowledge our indebtedness to Dr. Angus Fraser, of Aberdeen, for the details of Dr. Keith's practice which have previously appeared in the pages of the *Journal*, and also for the additional particulars which we commence this week. Dr. Fraser collected and arranged the notes of the cases at a time when Dr. Keith's failing health rendered such a task too irksome for his usually energetic mind. Dr. Keith was, however, able to revise part at least of the valuable experience which we now publish.

the exhaustion thus produced, and died at 8 P.M. on the evening of the 8th March.

CASE XVII.—George Davidson, aged 69, a farmer, came under treatment on the 10th April, 1842, and was operated on the 16th April. The stone weighed 2 ounces  $3\frac{1}{2}$  drachms, and measured  $2\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches. The operation was performed at his own home, forty miles distant from town, and an assistant remained with him until the morning of the third day after the operation. When he left the urine was clear and copious; the pulse 78, natural; the tongue clean and moist; in short, to all appearance the patient was out of danger. A surgeon in the neighbourhood took charge of the case then, and what happened subsequently has never been ascertained, except that a bottle of brandy was emptied by the patient on the third night, and that he died on the 20th April.

CASE XXVI.—Alexander Cavendish, aged 72, weaver, was admitted 29th June, 1843, and operated on on the 15th July, when a stone, weighing 3 ounces 7 drachms, and measuring  $2\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches, was removed. He went on tolerably well for some time, the wound very nearly healed, and he was able to be out in the garden. He had, however, been long subject to dyspepsia; the irritation of the stone had reduced his strength much; and, in spite of every care and treatment, it was found impossible to rally his strength. The stomach became very irritable, and he died of exhaustion on the 6th September, fifty-three days after the operation. The body, examined ten hours after death, was very emaciated. There was not the least trace of inflammatory action about the belly or pelvis. The kidneys were both studded with vesicles, like hydatids, and were granular. The viscera and chest were healthy. The head was not examined.

CASE XXIX.—John Abel, aged 77, farmer, was admitted on the 31st August, 1843, suffering from stone in the bladder, and was operated on at noon on the 16th September, when a stone, weighing  $3\frac{1}{2}$  ounces, and measuring  $2\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches, was removed. The depth of the perineum, and the unyielding state of the bladder, coupled with the size of the stone, made the operation (nineteen minutes and a half) both tedious and severe. The soft parts were considerably bruised; and a constant oozing from the surface of the wound required the tube to be enveloped in lint, and then twisted into the wound and bladder. About half-an-hour after the operation he fell rather suddenly into a state of collapse; brandy was administered, and he recovered in some degree, but the skin remained cold, the pulse feeble, and he continued in a low and drowsy state till 6 P.M. At 3 o'clock, he expressed a desire to pass urine; a catheter was therefore introduced by the urethra, and a quantity of warm water injected through it into the bladder escaped readily, untinged by blood, through the flexible tube in the wound. By 7 P.M. the pulse had become firm; the skin was still cold, and he was disposed to sleep. Arrowroot and brandy were administered. On September 17th, at 7 A.M., reaction was completely established. The heat of the body was perfect; the pulse firm. Urine had begun to flow clear, but in no great quantity. The skin was warm and moist; tongue dry; pulse 100, full. The belly was rather tense and tender. He was ordered warm diluents and poultices to the abdomen. During the day he became somewhat confused, and the belly became more tumid; he became very restless; his breathing became oppressed; and, after vomiting a dark-coloured fluid, he expired at 2 A.M. on the morning of the 18th. On a *post mortem* examination, the omentum was found adhering to the parietes by recently effused lymph; there was some bloody effusion behind the symphysis pubis; the small intestine, and also the sigmoid flexure, were of a deep crimson colour. There was bloody effusion round the whole of the bladder, especially at its neck; and the coats of the bladder were much thickened and indurated. The ureters were widely dilated, and the kidneys much disorganised.

CASE XXXII.—David Imray, aged 68, a farmer, was admitted into the Infirmary on the 14th December, 1843, and was operated on on the 17th February, 1844. The stone removed weighed 3 ounces 6 drachms, and measured  $2\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches. About thirty-six hours after the operation he became somewhat confused, but this confusion disappeared in the course of a few hours; it however returned again several times without any other very marked symptoms, till twelve days after the operation, when the bowels became loose; and, though this looseness was restrained by remedies, he gradually became weaker, and died on the morning of the 6th March, eighteen days after the operation. A *post mortem* examination was refused.

CASE XXXIX.—Robert Johnson, aged 74, a farmer, was admitted on the 16th April, 1844, and was operated on the 20th April. The stone removed weighed 13 drachms, and measured  $1\frac{1}{2}$  inches by 1 inch by  $1\frac{1}{2}$  inches. The night after the operation he complained much of flatulence and pain over the right kidney, both which symptoms were relieved by hot cataplasms. The following night he slept well, but the tongue became dry, and he was very weak; and, notwithstanding the

free administration of nourishment and stimulants, he gradually sank, and expired at half past 4 on the afternoon of the 23rd April. No *post mortem* examination was allowed.

CASE XLI.—Alexander Duncan, aged 63, a shoemaker, was admitted on the 28th May, 1844. On the 26th June, a stone, weighing  $2\frac{1}{2}$  ounces, and measuring  $2\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches, was removed. He went on well till the morning of the 29th, when the urine not coming by the wound, a catheter was introduced, and twelve ounces of urine were drawn off *per urethram*. He could not bear the presence of the catheter, which was left in, and it had to be removed in the evening, the urine then coming in occasional gushes by the wound. The urine became scanty, he gradually grew weaker, and died on the 3rd July, seven days after the operation. No *post mortem* examination was allowed.

CASE XLVI.—Adam Florence, aged 67, farmer, was admitted into hospital on the 27th March, 1845. He was a pale, weakly looking man, with a wasted worn-out body, a large scrotal hernia on the right side, and a dislocated patella on the same side. Animal food and wine improved him somewhat, and he was operated on the 19th April. The stone removed weighed 1 ounce 2 drachms, and measured  $1\frac{1}{2}$  inches by  $\frac{1}{2}$  inch by  $1\frac{1}{2}$  inches. He gradually became weaker, and expired on the 6th May without any other apparent cause than sheer feebleness of constitution. On examining the body, the contents of the abdomen were found quite healthy; the intestines were contracted to a small calibre throughout; the bladder was quite contracted and dark on its inner surface, with phosphate of lime in specks over it; the external wound was grey, soft, and ununited, no action having ever actively begun in it; the surface was coated with phosphate of lime; the kidneys were enlarged and diseased.

CASE LVI.—Thomas Imbree, aged 67, was operated on the 23rd August, 1845, when a stone, weighing 5 ounces, and measuring  $2\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches by  $2\frac{1}{2}$  inches, was removed. He died on the 15th September of sheer debility. No *post mortem* examination was allowed.

CASE LXIII.—Peter Emslie, aged 65, farmer, was admitted on the 18th November, 1845, and was operated on the 22nd of the same month. The stone weighed 1 ounce 6 drachms, and measured 2 inches by  $1\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches. The transverse perineal artery was of great size, and required a ligature. On the sixth day after the operation, when all danger seemed past, the nurse, on washing him, rudely detached the ligature, and, before she observed the occurrence, he had lost so much blood that he never rallied, and died on the 28th, twenty-three hours after the accident. No *post mortem* examination was allowed. A great mistake was made in not cutting both ends of the ligature short.

CASE LVIII.—George Peter, aged 78, a salmon-carter, was admitted on the 28th February, 1846, and was operated on the 25th March. There were three stones, weighing  $7\frac{1}{2}$  drachms, and the largest measuring  $1\frac{1}{2}$  inches by  $\frac{1}{2}$  inch by 1 inch. He went on well enough till the evening of the 27th, when there was slight tenderness on pressure over the belly, and the urine was not flowing so freely as before. Leeches were applied to the abdomen, but the pain became worse, the urine very scanty, the pulse feeble and frequent, and the breathing oppressed. He died at 9.30 A.M. on the 29th. On examining the body, the viscera of the abdomen were found very generally inflamed, the intestines glued together by recent lymph, patches of pus visible under the peritoneum, covering the rectum and sigmoid flexure. The kidneys were red, and partly in a state of fatty degeneration; there was no urine in the pelvis of the kidneys, ureters, or bladder. The bladder was thickened, but healthy to appearance; the wound in the prostate was of the usual limited size. On the right psoas muscle some bloody infiltration was noticed. There was no serous effusion whatever in the abdomen.

CASE LXI.—W. Finlay, aged 60, a farmer, was admitted on the 19th May, 1846, and was operated on the 27th June following. Two calculi were removed, weighing an ounce, and each measuring 1 inch by  $\frac{1}{2}$  inch by  $\frac{1}{2}$  inch. He went on well till the evening of the 9th July, when he became somewhat confused, his skin hot, pulse full and bounding, and 120; his breathing was hurried; there was no tenderness of the belly; the only appearance of local action was slight general fulness of the left leg and foot. He was bled to 30 ounces, and had 3 grains of calomel every two hours. On the 10th he was nowise improved; the breathing became more and more oppressed; and he died at  $7\frac{1}{2}$  P.M. On inspecting the body, the contents of the abdomen and pelvis were found perfectly healthy; the brain was congested, and there was large serous effusion between the membranes in both lateral ventricles and in the vertebral canal. The membrane lining the anterior surface of the left ventricle and auricle of the heart, and along the aorta, showed evidence of recent inflammation. It was afterwards discovered that he

had got eight ounces of port wine surreptitiously, and drunk it the night before the commencement of the unfavourable symptoms.

CASE LXVII.—John M'Intyre, aged 63, a pensioner, was admitted on February 17th, 1847; and on April 17th, a stone, weighing 2 ounces, and measuring 2½ inches by 1½ inches by 1½ inches, was removed. He went on for a few days very well; but after that time a troublesome cough came on, the result of chronic pulmonary disease, and he gradually became weaker, and died on the morning of May 14th. At the *post mortem* examination, the viscera of the belly and pelvis were found quite healthy. The right pleural cavity contained a large quantity of purulent effusion, and numerous vomices were found in both lungs.

CASE LXX.—Isaac Routledge, manufacturer, aged 73, came under treatment on May 22nd, 1847, and was operated on June 5th. Five calculi, weighing 1½ ounces, and the largest measuring 1½ inches by ¾ inch by 1½ inches, were removed. He died exhausted on June 28th from no very evident cause, the powers of life gradually failing under despondency. No *post mortem* examination was allowed.

CASE LXXI.—Alexander Davidson, aged 52, farmer, was admitted on October 9th, 1847, and on the 30th was operated on, when a stone, weighing 6½ drachms, and measuring 1½ inches by ¾ inch by 1½ inches, was removed. A pendulous polypous tumour was felt within the neck of the bladder, and on withdrawing the stone the excrescence came away in the angle of the blades. For some time after the operation the urine was bloody and mixed with coagula. In the evening the tube was removed, and, after being enveloped in lint soaked with tincture of matico, was reintroduced. On the morning of the 31st, the urine was more clear and copious; the wine which he had been getting during the night was continued; in the evening the pulse was too, as it had been since the operation; the urine was less copious, and the belly somewhat tumid. He passed a restless night, became confused, his pulse rose in frequency and became more feeble, and he died at 11 A.M. on November 1st. No *post mortem* examination was allowed.

CASE LXXIII.—John Topp, aged 63, crofter, was admitted on December 15th, 1847, and operated on December 25th, when two stones, weighing 3½ ounces, were removed. The larger measured 2½ inches by 1½ inches by 1½ inches. He went on well for twenty-four hours, but after that the urine became less and less in quantity, the pulse quick and weak, and the tongue dry, and he died on the 27th at half-past seven in the evening. At the *post mortem* examination there was not the least trace of inflammatory action in the abdomen or pelvis. The right kidney had numerous cysts on its surface, and Bright's disease had made some progress throughout the gland; the left kidney was atrophied, with the pelvis remaining like a bladder.

CASE LXXVI.—Peter Pirie, aged 45, farmer, was admitted on March 10th, 1848, and was operated on April 15th. The stone weighed 3 drachms, and measured 1½ inches by ¾ inch by 1 inch. He went on very well, and the wound had entirely closed; when he was attacked by erysipelas of the head and neck, then prevalent in the hospital, and died on April 29th.

CASE LXXVIII.—William Ross, aged 67, weaver, was admitted on August 22nd, 1848, and operated on September 2nd. Two stones, weighing 2 ounces 6 drachms, were removed, the larger measuring 1½ inches by 1 inch by 1½ inches. He went on tolerably well for ten days, the only unfavourable feature being a dry and a loaded tongue; after that time he began to get weak, became restless and confused, the pulse became feeble, and he died on the evening of the 18th. After death, the general aspect of the intestines was healthy; one kidney was much enlarged and diseased, and the ureter equal in diameter to a thumb; the other kidney was absorbed, its pelvis, like a bladder, only remaining. The left side of the pelvis contained a large quantity of thick pus. The prostate was much enlarged. The bladder was thick and rugose.

CASE XCIII.—James Abercrombie, aged 70, farmer, came under treatment on December 14th, 1850, and was operated on January 3rd, 1851. The stone weighed 5 ounces, and measured 2½ inches by 1½ inches by 2½ inches. The third lobe of the prostate came away before the stone; it weighed 6 drachms. Bilateral section of the prostate was required to let the stone out. Purulent phlebitis in the posterior tibial vein and in the deep veins of the left leg came on, and he died on January 14th. Pus was also found in the external iliac vein. He was operated on under the influence of chloroform; his wrists and ankles were secured by broad tapes during the operation; he struggled so violently in the course of the operation that phlebitis resulted in the external iliac vein, running up as far as the common iliac, and was the cause of death.

CASE XCV.—James Thom, aged 71, farmer, was admitted on January 5th, 1851, and was operated on the 25th of the same month. The stone weighed 3 drachms, and measured 1½ inches by ¾ inch by 1 inch. The urethra was torn previously to the operation by the assistant, in an

unsuccessful attempt to introduce the staff, followed by such hæmorrhage as to lead to the belief that the artery of the bulb had been torn. Great infiltration of blood took place into the penis and scrotum, and sphacelus of the latter speedily followed, under which he sank. Dissection showed the laceration in the bulb nearly an inch in front of the urethral incision for lithotomy.

[To be continued.]

## CUTANEOUS NEUROSIS.

By STANLEY HAYNES, M.D., Malvern Link, Worcestershire.

S. M., a strong, active, healthy, and intelligent girl of four years, complained on Tuesday, May 2nd, about midday, of feeling ill, but seemed so well that her mother, a kind and anxious parent, thought she was pretending. The child was unusually quiet, lay down all the remainder of the day, and was without appetite. No shivering was noticed. The following morning, instead of waking and getting up at six as usual, she slept soundly and uninterruptedly until twelve, when she appeared poorly, and was as on the previous day. In the evening, the child was lame and in pain; and her left great toe was found cold, blue, and swollen. On the 4th, I found the left foot and ankle blue, cold, swollen, and painful. The posterior tibial and dorsal arteries pulsated naturally, and no obstruction to the venous circulation was noticeable. The left hand was somewhat swollen, and there was some lividity about the finger-nails. This hand and the lower half of the forearm, and the right foot and ankle, had been in similar conditions to those in which the left foot was at the time of my visit; and all three had been very painful. The eyelids on both sides were rather and equally cedematous; and the face was swollen; the lids had been affected in the same manner as the other parts. Neither the right hand or arm nor the ears had been involved. The feet had been bathed in hot water with mustard. I directed the limbs to be wrapped in cotton wadding, and prescribed a mixture with aromatic spirit of ammonia and spirit of chloroform. The child had seen a funeral on the 2nd, but did not appear to have been frightened in any way. She was as intelligent as usual; seemed quite free from vertigo and nausea and any evidences of ergotism; her expression was rather anxious; she had taken little food; and the bowels had acted in the morning. The state of the urine had not been observed. The cardiac sounds were normal; the pulse 82. At bedtime, after some slight reaction—local pain and redness, but no sweating—the various parts had resumed their natural appearances.

The child continued well until the following morning (May 5th) at eight, when both feet became affected as before, continuing so until late at night. The patient was very poorly all day; had anorexia and thirst; her face (only) perspired copiously; and her pulse in the evening was 140. The urine was non-albuminous, loaded with magnesian phosphates.

In May 1870, a playmate thrust a piece of velvet into the child's left nostril. Her mother attempted to remove it, but pushed it beyond reach and sight. Soon afterwards, some foetid discharge came away; and, at various times during the summer, threads were expelled; none were noticed for some months; but the ozæna continued, and became so bad that the child could not be received at school. A month ago, I chloroformed the patient (as she was much frightened by any attempt to examine her nose), and endeavoured—in vain—to find and wash out any remains of the velvet. The discharge (for which a solution of carbolic acid had been used for three months) continued as before until this illness. On May 5th, there was not any discharge or bad odour. On the 6th, the child seemed pretty well; there was not any unnatural appearance, and the ozæna returned in the afternoon. The 7th passed without anything abnormal, and it was hoped the child had recovered; but on the 8th the left foot again became affected as before, the condition extending into the calf, and ending gradually. The ozæna continued. Both feet were very much attacked on the 9th. The little patient was as ill as on the 5th, with profuse sweating of the forehead; and the ozæna was arrested. An ounce of the following mixture was now given four times daily.

R Potassæ chloratis, gr. xxv; tinct. ferri perchlor., spir. chloroformi, ana ℥i℥ss; syrupi simpl. 5j; aquæ dest. ad ʒviij.

The feet were kept in cotton-wadding, and in the evening were restored to their natural condition. On the following day (10th), the only abnormal state was coldness and some lividity of the posterior aspect of the lower half of the right arm; this lasted two or three hours during the middle of the day. Between ten and eleven in the morning of the 11th, both feet became much affected and very painful, with sharply defined straight lines of demarcation, until about 3 P.M., when they resumed

their natural appearance in about an hour. The patient appeared well until the succeeding evening (12th), when the left hand was attacked up to the carpo-metacarpal articulations, corresponding with which was a distinct boundary line. On the 13th, the right hand was slightly affected in the morning. In the middle of the day, the wrist also was very much involved, and was bounded from the arm by a distinct line. The parts were almost quite restored in the evening. The *ozæna* was profuse. When the child was undressed on the 14th, her parents observed a dark yellow coloration, extending the entire length of the spine, about an inch in breadth. During that day, the only other symptom noticed was, that the left elbow was decidedly colder than the right. On the 15th and 17th, the child was quite free from all abnormalities excepting the *ozæna*.

These attacks came on suddenly, the various parts affected having been seen to change from their natural condition to blue-black lividity, cedema, coldness, and hyperæsthesia, in the course of a few minutes—in some instances, five minutes sufficing for the alteration. The recoveries were less rapid, but sometimes occupied some minutes only; at others, about an hour. They occurred at various periods of the day, and appeared to be irrespective of reception of food and various external conditions—of warmth or cold, wet or dry days, or of mental emotions. Throughout, the child had similar food to the other children of the family, and was the only one affected, and had never before ailed in a similar manner. Her father is a healthy, strong agricultural labourer; her mother is a robust and vigorous, but faint-hearted woman. Between the attacks, the patient ran about and played as usual. Sometimes while playing, at others while in bed or sitting still, she complained of pain; and then some part was found to be becoming affected. While the neurosis remained, the child was in pain, wanted to lie undisturbed, and had anorexia. The attacks sometimes lasted all day, and sometimes passed off quickly; they ceased more rapidly during the last days than when the neurosis began.

It will be observed that the left side was most affected; that the discharge from the nostril of the same side (to which it is limited) was suppressed when the symptoms first appeared; and that, when the *ozæna* returned on the 6th, the pseudo-gangrenous appearances ceased, but only for a time: they recurred occasionally, although the *ozæna* continued; so that the nasal discharge and the symptoms did not appear, as at first, to exist in any relation to each other.

There has not yet been any perceptible desquamation; nor is any expected, as the skin of the various parts has throughout been soft and pliable. During the recurrences of the neurosis, the weather has been, for May, unusually cold.

In Dr. C. Handfield Jones's work on *Functional Nervous Disorders* (at p. 472 *et seq.*) are some remarks on, and cases of, somewhat analogous attacks to that now adduced.

Since the above was written the *ozæna* had ceased. One day in June the child expelled a foetid mass (which probably contained the remains of the velvet), and its nose has been quite free since then.

### SANTONIN AS A PARASITICIDE.

By DAVID PAGE, M.B. Edin., Kirkby Lonsdale, Westmorland.

SOME time ago, the efficacy of santonin in destroying intestinal parasites, and the peculiarity of its effects on the system, now and again observed, received a passing notice in the pages of the JOURNAL. I wish on this occasion to add a remark or two in the same direction, furnished by cases lately under my observation.

In the first of these, a healthy-looking girl, aged 12, was brought to me, suffering from loss of appetite, toothache, white-furred tongue, and symptoms generally indicating an irritable state of the *primæ viæ*. Her mother told me that, for some weeks, the navel had been the seat of great pain and uneasiness, and there were now much redness and tenderness to touch. The failure of domestic medicine had alarmed the frugal housewife, and induced her to seek a remedy elsewhere. I suspected, from the above symptoms, that the *ascaris lumbricoides* was lurking within the small intestines, and so gave her five-grain doses of santonin, to be taken at bedtime, followed next morning by eight grains of the compound scammony powder, to be taken early before breakfast. This treatment was to be repeated for three successive nights; but, on the morning after the second dose, I was informed that two round worms had come away by stool. One of them, which had been kept for my inspection, I found to measure fourteen inches in length. A week later, I repeated the medicine, but without any result, and the girl had already recovered her former good spirits and appetite. In spite of the large quantity of santonin administered, there was no disturbance of the eyesight or other function.

In the second case, I was consulted a fortnight ago by a country gentleman, about his youngest son, a bright little boy, aged 5, but whose health began to cause the parents much anxiety. I found him showing all the signs of a general derangement of the gastro-intestinal tract, characterised by a very capricious and fastidious appetite, and a pale tongue, with enlarged papillæ, and a slimy yellow coat along the dorsum. His bowels, too, were sluggish, and his sleep was often disturbed by waking and cries. Though, certainly, here the primary condition was a catarrhal state of the *primæ viæ*, I considered that, if the irritable symptoms depended upon parasites finding a comfortable and luxurious habitat in the excessive mucus adherent to the intestinal walls, the most prudent step would be their removal before proceeding to a tonic treatment proper to the catarrh. Santonin was therefore given as in the foregoing instance, and syrup of senna substituted for scammony, as less likely to irritate the bowels. Perhaps the old-fashioned compound decoction of aloes might have been preferable to either, seeing that the aloetic drug exerts a special stimulant and bracing action upon the small intestine, helping it to shake off the viscid mucus and allowing free osmosis to the fluids of the choked-up glands. At any rate, the immediate effect of the treatment was to dislodge a whole colony of the oxyuris or threadworm with masses of jelly-like mucus. After the first dose, much alarm was excited when it was discovered that my little patient had involuntarily passed during sleep a large quantity of urine which stained the bed-linen bright yellow. This, I had to explain, was one of the occasional effects of santonin. The eyesight, however, was not affected. I see in Ringer's *Handbook of Therapeutics*, that santonin is recommended as a remedy for the nocturnal incontinence of urine in children.

### CLINICAL MEMORANDA.

#### INTERMITTENT HÆMATURIA OF MORE THAN TWENTY YEARS' DURATION IN AN AGED WOMAN.

MRS. B. of Plymouth, aged 75, of a nervous and rather sanguine temperament, ceased to menstruate at 49; and from that time to the present, a period of twenty-six years, has been subject to attacks of intermittent hæmaturia, coming on at irregular intervals, without pain, and continuing for some months at a time, in spite of continued rest in the horizontal position; the constant use of iron, lead, gallic acid, and iced lemonade, being frequently administered as a drink when thirsty. The pulse is natural, the tongue clean, the countenance rather anemic. She complains of debility. The urine is normal in quantity, but deeply coloured with blood, which becomes deposited in a thick grumous layer at the bottom of the utensil on the urine becoming cold. No more albumen is obtainable than may be accounted for by the presence of the blood in the urine, which is of specific gravity 1015. No premonitory symptoms have characterised these attacks, such as pain, or a sense of weight at the loins, etc. The appearance of the blood has been more venous than arterial. The question naturally arises, What is the peculiar pathological condition in this extraordinary case? Has it been simply arising from periodic passive congestion of the kidneys, or has it been parasitical? Calculi, I think, may be excluded, from the total absence of pain. If not parasitical, I am inclined to regard it as a salutary effort of nature to prevent venous congestion of the system arising from the suppression of an accustomed discharge of blood.

J. N. STEVENS, M.R.C.S.E.

Princess Square, Plymouth, July 31st, 1871.

#### EFFECTS OF THE VAPOUR OF AMMONIA IN THE TREATMENT OF WHOOPING-COUGH.

IN consequence of the benefits which patients have received by the inhalation of the atmosphere containing sulphuret of ammonia in the purifying-room of the gas-houses in whooping-cough, when the disease is in its last stage (that is, after the third week), I conceived the idea that ammonia might be more potentially administered in the form of moist vapour by means of my "brick bath", an account of which I published in the BRITISH MEDICAL JOURNAL for August 20th, 1864. Accordingly, in cases which I have had recently, I had one ounce of the strongest liquid ammonia put into a gallon of boiling water in an open pan, and the steam kept up by means of half a brick made red-hot throughout and put into the boiling water containing the ammonia, and placed the pan in the centre of a room, into which I had the patients brought as the ammoniated steam was passing off. This method was used in the evening, just before bedtime; and it has been so efficacious in abating the spasmodic attack, and after three or four

days terminating the malady, that I cannot over-estimate the great value of this mode of inhaling the ammonia as a therapeutic agent in tranquillising the nervous system in whooping-cough.

JOHN GRANTHAM, F.R.C.S. (Hon.).

Crayford, August 24th, 1871.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### THE NOSOLOGY AND TREATMENT OF DIARRHŒA, CHOLERINE, AND ASIATIC CHOLERA.

IN view of the approach of Asiatic cholera, and of the prevalence at this season of ordinary forms of autumnal diarrhœa, it has seemed to us opportune to lay before the profession notes of the opinions and practice of Metropolitan Hospital Physicians on the nosology and treatment of autumnal diarrhœa, English cholera and cholerine, and Asiatic cholera. The particular points as to which it seemed desirable to ascertain the views of hospital physicians, related to the symptoms, if any, which establish the nosological distinctiveness of these diseases, and the treatment which each physician favours. The following notes represent some of the first results of our inquiry; and we hope to receive further communications from those physicians in town and country who have not yet furnished us with their views, or to whom we have not been able to address individual communications.

##### KING'S COLLEGE HOSPITAL.

DR. GEORGE JOHNSON is of opinion that, apart from the history of an epidemic, there are no signs by which autumnal diarrhœa, English cholera, and Asiatic cholera, can with certainty be distinguished from each other. Every summer and autumn there occur sporadic cases of English cholera with collapse and rapid death, which during an epidemic of Asiatic cholera would be indistinguishable from the latter disease. On the other hand, during a cholera epidemic there occur many cases of diarrhœa which are cases of Asiatic cholera in a mild form, yet not to be distinguished by any positive symptoms from ordinary cases of autumnal diarrhœa or English cholera. With regard to treatment, Dr. Johnson attaches more importance to abstinence from the administration of opium in the early stages of diarrhœa than to any positive remedial measures. He maintains that, by the early and indiscriminate use of opium even in small doses, either the diarrhœa is prolonged, or its abrupt arrest is followed by painful distension of the bowels, by fever, and sometimes by collapse. He believes that rest and diluents (cold water) will suffice for the cure of most curable cases of choleraic disease; but he gives evacuants when diarrhœa is attended with pain, when the discharges are offensive, and when palpation and percussion of the abdomen show that the bowels are distended by morbid secretions. This rule of practice he applies both to the diarrhœa and to the collapse stage; but he considers that the probability of recovery from extreme collapse is scarcely greater than the chance of recovery from embolism or thrombosis of the pulmonary artery. With reference to the use of opiates, Dr. Johnson maintains that the true principle is this: opiates are often useful to soothe irritation after the evacuation of the bowel; they are useless and even dangerous when the blood is poisoned, or the bowel filled with morbid secretions. Opiates in the early stage of choleraic diarrhœa would, he believes, be more frequently and decidedly injurious were it not for the fact that, their absorption being prevented by the active eliminative efforts, they are quickly expelled with the morbid secretions, and they are therefore powerless to arrest the discharges. The administration of opium and alcohol during the stage of collapse has been demonstrated to be an irrational and a deadly practice.

The term English cholera, or choleraic diarrhœa, Dr. KELLY remarks, is in many cases apt to mislead, as it seems to imply that there may be a combination of real Asiatic cholera and the ordinary diarrhœa, which is generally very common in the autumn. By the term Asiatic cholera should be understood a disease depending on a specific morbid poison, which is very liable to be communicated from one person to another, and which is attended with very fatal results in the district in which it occurs. But there is no evidence of any poison in the cases of ordinary autumnal diarrhœa; a *toxin* cause seems to be an unduly relaxed condition of the mucous membrane of the alimentary canal in hot weather,

so that any error of diet will readily produce an increased flow from the bowels. In such cases the diarrhœa may be the only symptom, or it may be attended with more or less griping, pain, and sickness; but when, in addition, there are great vomiting, prostration, and cramps in the legs, then the case is termed one of English cholera; nor need such a term be discarded if it be used to signify a severe form of diarrhœa, and not a modified attack of Asiatic cholera. At the present time, for instance, there is no case of true cholera, while diarrhœa, in its mild and severe forms, is very abundant. But, just as in an epidemic of typhoid fever a certain number of persons will seem to have all the symptoms of a very slight or abortive attack of that disease, so when cholera is in our midst there will be cases in which persons are affected in a very slight degree, and diarrhœa is, perhaps, the only symptom. In such cases we are ready to assume either a small dose of the poison or a want of susceptibility on the part of the individual to the effects of the poison; and in this sense it is quite true that diarrhœa and cholera are associated terms, and that the former is a modified form of the latter. But when Asiatic cholera has not appeared on our shores, it is not right to say that an ordinary case of diarrhœa may run on into true cholera, although it may pass on into that severer form which is termed English cholera.

For the treatment of diarrhœa in its milder manifestations, a dose of castor-oil, taken at bed-time, seems to be the best remedy; and this is chiefly the case where some indigestible food has been taken, and where there is griping pain with distension of the abdomen. At the Evelina Hospital for Sick Children, Dr. Kelly has found such treatment most beneficial. It is not needful to persist in giving castor-oil; one dose, so as to relieve the bowel of any peccant material, will usually suffice. It is very useful afterwards to give some aromatic mixture containing rhubarb, soda, and aromatic chalk-powder, flavoured with some essential oil. In children, however, dentition and bad feeding are very rife causes; and then a more careful diet with a simple saline will generally suffice.

In severe cases, where there is much vomiting, iced water or iced milk is very useful; and if there be much pain or cramps in the legs, hot flannels are of much service. Opium and astringents do more harm than good; and it is far better to begin with some mild aperient, and afterwards give some stomachic mixture. It has very often happened that children have come to the Hospital with diarrhœa who have been taking chalk mixture; and the almost invariable account the mothers give is, that at first it seemed to do good, and then sickness and distension came on, and the diarrhœa returned. In such cases, one or two drachms of castor-oil and mucilage will give great relief; or a rhubarb and soda powder may be given at bedtime.

Diarrhœa in children is often caused by the milk turning sour in hot weather; this may be in great part avoided by using the condensed Swiss milk, which keeps very well and is sweet and palatable. Cooked fruit may be eaten, but unripe fruit of all kinds should be avoided when there is any looseness of the bowels. Beer and porter may cause diarrhœa; and this often seems the case with labourers who, after perspiring freely at their work, then drink freely of some inferior or, perhaps, sour beer. In cases of diarrhœa, the food should be very simple, and only a little taken at a time; all fluids should be taken cold, and sucking small pieces of ice slowly is very grateful. As a rule, stimulants should be avoided.

##### WESTMINSTER HOSPITAL.

DR. FINCHAM believes that a high temperature is the main cause of summer or autumnal diarrhœa. This is injurious to the system in two ways: firstly, it overstimulates the liver, hence the secretion of an undue amount of bile, which acts as a direct irritant upon the stomach and bowels, vomiting and purging being the result. The decomposition by excessive heat of animal and vegetable matters is the second great source of summer diarrhœa. Noxious gases are generated, and, like the atmosphere of the dissecting-room, produce, if absorbed, the symptoms of an irritant poison.

As regards the treatment of such cases, Dr. Fincham knows nothing better, when the patient is seen at the onset of the malady, than the old-fashioned dose of three grains of calomel and half a grain of opium, followed in a couple of hours by the equally old-fashioned rhubarb draught. This may be repeated, if necessary; and afterwards, should the diarrhœa continue, a draught, consisting of bismuth, soda, and a few drops of laudanum, given three or four times a day, is sufficient to complete the cure. Should the patient not be seen until the purgings have lasted, it may be two or three days, he sees no reason to give the purgative, but order the bismuth, etc., at once: to give, however, as is by no means uncommon, astringents at the onset of the attack, is bad practice, and ought to be discontinued.

The so-called English cholera, in which, in addition to vomiting and

purging, cramps of the abdominal and other muscles, with more or less tendency to collapse, are present, is, Dr. Fincham believes, in ordinary seasons only an aggravated form of the ordinary summer diarrhoea. When, however, Asiatic cholera is impending or present, it must often be difficult to decide whether a severe case of apparently English cholera may not be due to the poison of the graver malady. Nor does he know of any symptom which can lead to a decision except the presence, not merely of serous, but of true rice-water, evacuations. These may be looked upon as pathognomonic of genuine Asiatic cholera. If they be not, he does not see how any distinction can be made. With respect to the treatment of English cholera, the first thing to insist upon is, that the patient should at once go to bed and be kept warm by means of hot bottles, etc.; a large linseed poultice, as hot as it can be borne, being at the same time applied to the abdomen and loins: it of course must be frequently changed. Should the purging have already lasted some time, a draught, consisting of half a drachm of chloric ether, with fifteen drops of laudanum, should at once be given, unless there should be much vomiting, in which case a grain of opium in a small pill should be substituted, to be followed by a tablespoonful of brandy in soda-water as soon as the state of the stomach permits. Should the cramps and tendency to collapse appear simultaneously with, or shortly after, the onset of the diarrhoea, the calomel and opium pill should then be given, to be followed either by the rhubarb draught or by a tablespoonful of castor-oil; the application of external heat, especially the poultices, being equally insisted upon. Should the diarrhoea continue, the bismuth and soda draught, with a few drops of laudanum, should be given, as in the case of the less severe form of the malady.

As regards the treatment of Asiatic cholera there can be no question that, when the stage of collapse has set in, all astringent opiates and stimulants are worse than useless. Copious draughts of iced water, a solution of chlorate of potash, in the proportion of two drachms to the half-pint of water, given in two-ounce doses every hour or two, and Liebig's beef-tea, as recently suggested by Dr. Lowndes in a contemporary, are pretty nearly all that can be taken with advantage. During the stage of reaction the same plan may, in the main, be pursued. Hot baths do not seem to be of any use; but Dr. Fincham would be much disposed to recommend the application of hot poultices to the loins, in the hope of sooner restoring the function of the kidneys. As to the debated point whether astringents or evacuates are to be given in the early stage before collapse has set in, he would be disposed to follow the same rule as in the case of English cholera. Should the purging have been of considerable duration, he would give the dose of chloric ether and laudanum, keeping the patient in bed and applying sedulously hot poultices. Should the purging have only lately come on, then the calomel and opium, followed by a dose of castor-oil, would be, he thinks, the appropriate treatment. Iced water can at the same time be used *ad libitum*, and Liebig's beef-tea given as in the stage of collapse.

#### GUY'S HOSPITAL.

DR. HABERSHON says that attacks of *autumnal diarrhoea* are accompanied with, and are probably dependent upon, hepatic disturbance. The secretion of bile is changed; at first its quantity is diminished, and it is irritating in character, but afterwards the flow is greater than usual. The symptoms of autumnal diarrhoea are nausea, with uneasiness in the abdomen; colic; diarrhoea; the discharges consist of mucus with bile, with or without scybala; the tongue is furred and injected; the pulse is compressible, and there is considerable prostration of strength. Sudden changes of temperature, chill to the surface of the skin, cold drinks, and undigested food, will each induce the disease; and in the latter case, the colic is sometimes very severe.

Since autumnal diarrhoea is essentially connected with intestinal disturbance, the tendency of which is to subside as soon as the cause is removed, we generally find that rest in the recumbent position, warmth to the surface of the abdomen, and bland demulcent diet, as arrowroot, mutton broth, etc., will alone suffice to relieve the disease. The diarrhoea should be checked by aromatic astringents and opiates; and, if the colic be severe, the opium should be used freely. If, however, irritating food or excreta be present in the intestinal tract, it is useless to administer astringents and opiates; and the old remedies of castor-oil and tincture of rhubarb are of greater value. Grey powder or a small dose of calomel with Dover's powder, followed by a warm aperient draught, will effect a similar useful purpose, and will remove these offending matters.

In *English cholera*, there is the same disturbance of the hepatic function, but the symptoms are more sudden in their commencement, and there is greater irritability of the stomach, violent vomiting being present with the purging. The colic is often severe, and there are also cramps in the legs; prostration of strength is more speedily induced, the surface of the body becomes cold and clammy, and the pulse scarcely percep-

tible. There is a close resemblance to Asiatic cholera in the condition just described; but there is not the same lividity of countenance as in malignant cholera, nor does the voice have the same character as in the latter disease, nor does the breath become so decidedly cold. The motions in English cholera may consist of thin watery mucus like the washings of beef; but the rice-water motions of Asiatic cholera are not observed, nor do we find any secondary fever as the prostration disappears.

At the onset of English cholera, the diarrhoea should be checked; opium and astringents may at first be used freely with advantage, and afterwards dilute sulphuric acid with spirit of chloroform. If there be retained excreta, the same means should be used as were mentioned for diarrhoea.

In *Asiatic cholera*, the nervous shock is more severe, and the stage of collapse is more quickly produced. In a few hours, even without diarrhoea, a patient may be in a state of hopeless collapse. Not only does the function of the liver become checked, but that of the whole of the vaso-motor nerves receives a sudden arrest; and there appears to be as much reason to ascribe the disease to the interrupted nerve-function of one part as of another—the heart as much as the lungs, the kidneys as much as the liver.

If there be any *preliminary* diarrhoea, it is a judicious plan to check that diarrhoea; but, in the cold stage of cholera, the vomiting and purging are not relieved by opiates and astringents, and there is greater fear of secondary fever and of coma if those remedies be employed. It is now well established that opiates and stimulants increase the danger of a fatal result in Asiatic cholera; but, where diarrhoea precedes the more severe symptoms, it is a wise plan to check that diarrhoea by every means in our power. At the present day, there is a tendency to run wild upon hypotheses of elimination; and it is one of the great impediments to our progress in scientific medicine when we go beyond and before established facts. Patients recover from Asiatic cholera under treatment the most diverse; calomel treatment and cold water treatment appear to be equally effective; and saline medicines, camphorated stimulants, and castor-oil have statistical returns of nearly equal value. Castor-oil in the cold stage of cholera can only be recommended as being *less* injurious than opium and ardent spirits. External warmth should be applied to the surface of the abdomen, friction should be used to the extremities, and demulcent drinks given to the patient, as arrowroot, ice-cold water, mutton broth, etc. The apparently beneficial effect from spirits of camphor would lead to its further use combined with ammonia and with quinine in full medicinal doses.

#### ST. MARY'S HOSPITAL.

DR. F. E. NUNNELEY is of opinion that the symptomatic distinctions between diarrhoea, English cholera, and Asiatic cholera, depend chiefly on the extent to which the nervous system is implicated in the disease. In simple diarrhoea there are few nervous symptoms—trifling or moderate pain, and only slight feelings of prostration; in English cholera the prostration becomes severe, muscular cramps are added, and there is great depression of the powers of life; whilst in the collapse of Asiatic cholera these symptoms reach their extreme development; and the processes of digestion and assimilation, which are slightly interfered with in the first, and gravely so in the second, are in this almost abolished—a further evidence of the profound changes which have occurred in the nervous system. It is on considerations such as these that different names are given to cases of diarrhoea of varying severity. Thus, if there be merely looseness of the bowels, the disease is called simple diarrhoea; and if there be great prostration, together with cramp, English cholera is the name assigned. A common form of diarrhoea, more especially with children, is that in which blood and slimy mucus are passed with the stools, and there is much straining: it may be called dysenteric diarrhoea.

Asiatic cholera is markedly distinct from any kind of diarrhoea, though the diagnosis, which in individual cases is not always easy, mainly rests on its essentially epidemic character, on the early and profound implication of the nervous system, on the rice-water stools, and on the fatal tendency of all the early cases of an epidemic.

Summer diarrhoea in numerous cases appears to depend on some general conditions of atmosphere or temperature, which also give rise to catarrh of the bronchial mucous membrane, often coincidently with that of the intestines.

Though diarrhoea never becomes either cholera or typhoid fever, it renders the subject of it especially susceptible to these contagions, and on this account the treatment of all forms of it, whether slight or severe, should be directed to the early and complete suppression of that condition which is common to them all; viz., an increased and altered discharge from the bowels, together with nervous depression. This remark applies to those cases which are attributed to some "peccant"

matter in the intestines, and for the removal of which an aperient is often considered necessary; but the irritant is far better got rid of in the form of solid stools and unattended by prostration, than by purging, and this end is promoted rather than hindered by moderate doses of opium with some astringents, which assist in restoring the intestines to the condition of health. An useful formula is—*Misturæ cretæ* ʒj; *tincturæ catechu* ʒj; *spiritus chloroformi* miv—x; *tincturæ opii* miv—x, given every four hours; or *acidi sulphur. diluti* mx—xx; *spiritus chloroformi* miv—x; *tincturæ opii* miv—x; *aqua* ʒj. The dysenteric diarrhoea, so common in children, yields readily to castor-oil, in doses of from 5 to 10 minims, with a few grains of sugar and gum arabic, to which, in severe cases, from one-sixth to half a minim of tincture of opium can be added.

Since pathology has not yet enabled us to frame a rational system of treatment for Asiatic cholera, we are limited to the tradition of experience and to treatment on general principles, such as checking excessive evacuation and supporting the powers of the patient; but amongst special methods, an earlier and more systematic resort to the injection of saline solutions into the veins appears to give most promise of success.

## MERCER'S HOSPITAL, DUBLIN.

### TREATMENT OF GANGLIA.

(By MR. LEDWICH.)

THE following should have appeared in our report on the treatment of ganglion. The manuscript, however, was mislaid.

In the treatment of those sometimes very troublesome affections, Mr. Ledwich, like others, had tried many methods in order to effect a cure; but he has latterly abandoned them all with the exception of two—viz., puncture and seton. Mr. Ledwich, however, has never recourse to the latter but with extreme reluctance, and only after every other means have failed, as, even with the greatest exercise of caution and closest watching, untoward symptoms will occasionally ensue, quite sufficient to excite in the mind of the operator no small amount of anxiety and alarm. The method by puncture is, he conceives, above all others the least liable to objection, as it is generally free from all dangerous consequences, and most certain in its results where properly done; in fact, Mr. Ledwich has known it to succeed in almost every instance where several other methods have been tried ineffectually. The operation in its nature is most simple, as all that is required for the purpose is a common sharp-pointed bistoury, with which a small puncture should be made in the ganglion, previously made tense between the finger and thumb of the left hand. About one-half of its contents should be allowed to escape, and the point of a small glass syringe, previously filled with the compound tincture of iodine, having been introduced into the opening, a quantity about equal to what had been allowed to escape should be injected into the cavity. The instrument should be then gently withdrawn and a piece of lint soaked in cold water applied, with strict injunctions to keep the part at rest for the next twenty-four hours. The operation in itself is attended with very little pain, as all that is complained of is a slight sensation of heat and burning, which may last for an hour or two, or perhaps a little longer. When the part is examined on the ensuing day, if the fluid employed have been of the proper strength, the following appearances may be observed: a slight blush of inflammation over the part, the swelling feeling harder and firmer to the touch; pain in a moderate degree experienced on pressure; the small puncture closed, and no discharge visible. Under those circumstances, it is always better not to interfere with it until another twenty-four hours shall have elapsed, when it will be found to be harder, firmer, and more sensitive to the touch. The blunt end of a probe may now be employed to open the original puncture; and when this has been done, a quantity of matter mixed with blood will escape, when the ordinary treatment with bandage and cold water dressing will, in the great majority of cases, ensure a complete and permanent cure. It may, however, be necessary to add that, if after the first twenty-four hours the part should fail to exhibit the appearances described—in short, a sufficient amount of inflammation as would appear to be necessary to accomplish the object in view not having been induced—the puncture should be at once reopened and the injection, with its strength more or less increased according to circumstances, be repeated.

There is no doubt whatever that the seton must be always more certain in its results, and more especially so where the threads have been soaked in either the tincture of iodine or a solution of nitrate of silver; but it is so often attended with a high degree of risk arising from the resulting inflammation, which may extend in every direction and assume a very dangerous character, that Mr. Ledwich believes few surgeons

will have recourse to it except as a last resource, and only in those peculiar cases where other measures have been fairly tried, and have failed in achieving the object in view.

## NORTHAMPTON GENERAL INFIRMARY.

### CASE OF BELLADONNA POISONING.

(Under the care of Mr. Mash.)

WE are indebted to Mr. Carruthers, House-Surgeon, for the following account.

In the following very interesting case, there was no disturbance of the due relation between the respiration and circulation. There was no gay delirium; no diplopia. The rash was confined to the head and face, and there was no desquamation of cuticle. Some of the contents of the patient's stomach was applied to the conjunctiva of another patient, likewise some of her urine to another; in both cases rapid dilatation followed. Every day a drop of urine was applied to a healthy conjunctiva, and so long as the patient's pupils continued dilated, for so long was her urine capable of causing dilatation of the subjects' pupils; thus showing that the elimination of the poison from the system was coincident with the return of the patient's pupils to their normal state. The absence of delirium was possibly due to the large quantity of belladonna taken, so exerting a narcotic effect very rapidly. The case was treated entirely by the eliminative method, for the small quantity of morphia administered exerted no appreciable effect.

H. M., aged 38, married, suffering from secondary cancer of the breast, was admitted on April 30th into the General Infirmary, Northampton, under the care of Mr. Mash. She was generally cheerful in demeanour, though occasionally despondent on account of the unfavourable prognosis of her case. At 5.45 A.M., on May 6th, she got out of bed and took a teaspoonful of extract of belladonna and glycerine, which had been used as an application to her breast. Half an hour afterwards, she told the night-nurse what she had done. Mr. Carruthers saw her immediately, taking with him a drachm of sulphate of zinc. From the symptoms present, he saw that there was no doubt of her having taken belladonna, so he at once gave the emetic and prepared the stomach-pump. He did not wait for vomiting, considering the length of time which had elapsed since the poison was swallowed, but at once used the pump. About two gallons of water were passed into the stomach; in the first half gallon there was a quantity of belladonna. The pump was kept going until the fluid ejected was quite clear and free from smell.

When she was first seen, there was no dysphagia, delirium, nor convulsive movement. Pulse somewhat rapid. After the emesis, three drops of croton oil were administered. Fluids were swallowed readily. After this a copious enema was used, which brought a small quantity of scybala away. She now became nearly unconscious, but still able to swallow; so strong coffee and brandy were administered. After about fifteen minutes, she became unable to walk from loss of co-ordinating power in the muscles of the lower extremities. She was then put to bed, an enema composed of two ounces of brandy and coffee was administered, and repeated in half an hour, and again used after the same interval.—8.30 A.M. She was quite unconscious; breathing was diaphragmatic, not stertorous. The countenance was flushed; the pupils were widely dilated; the pulse was feeble, but regular; there were spasmodic twitchings of the arms and legs; the conjunctivæ were sensitive to the touch. A third of a grain of morphia was injected subcutaneously, and a small quantity of extract of Calabar bean in solution was applied to the left conjunctiva, producing slight contraction of the pupil of that eye.—9 A.M. Another enema of beef-tea and two ounces of brandy was given; and sixteen ounces of urine were withdrawn by the catheter.—3.15 P.M. She had manifested some consciousness; she tried to reply when spoken to, and was able to swallow. She had vomited once. The pupils were still widely dilated; the breathing laboured; the pulse 60, soft; while there was still some twitching of the hands, but quietude of the legs.—12 P.M. The face was highly suffused; the pupils were still widely dilated, and although not sensitive to light, she could perceive the difference between the face and back of a gold watch. There was no diplopia. She had still some tremulous movements in attempting to hold anything. Pulse 140, soft. The patient was conscious, and expressed anxiety to recover.

May 7th.—The bowels were opened four times in the night; the evacuations were very loose, some of them liquid; pulse feeble (84); the pupils were contracting, though not sensitive to light. She complained of pain on attempting to swallow. Vision was much improved; she was quite coherent, and complained of hunger. The suffusion of the countenance was subsiding. She could tell the time by a watch. In the evening the pulse was 84, soft; the tongue clean; deglutition

was easier. The countenance was still suffused, though less so than in the morning.

May 8th.—Pulse 100. The patient was still improving. The countenance was tranquil and natural; the tongue somewhat brown; deglutition was more easily performed; the bowels were open.

May 11th.—She had now quite recovered from the effects of the belladonna. The pupils were normal. The dysphagia had quite disappeared.

## REVIEWS AND NOTICES.

**INSANITY AND ITS TREATMENT:** Lectures on the Treatment (Medical and Legal) of Insane Patients. By G. FIELDING BLANDFORD, M.D.Oxon. Edinburgh: Oliver and Boyd. 1871.

THE thanks of the profession and of the student are due to Dr. BLANDFORD for the production of a work on insanity, eminently practical, lucid, and, above all, medical. It is this latter characteristic which most particularly recommends it to the student and practitioner. Insanity is spoken of as a disease of the body. No metaphysical or psychological dissertations are introduced whereby, the purely physical nature of the various diseases treated of is obscured. Mental phenomena are discussed shortly and tersely by the physician and physiologist, and are solely regarded from the objective aspect—the aspect from which every practitioner of medicine practically views them, however strongly he may in theory advocate the positive system of philosophy. Dr. Blandford has done well in departing from the time-honoured practice of beginning a book on mental diseases by raising a metaphysical ghost which is never satisfactorily laid in subsequent chapters, but, on the contrary, is ever always standing upright, an immaterial bugbear, a phantom finger-post pointing the wrong way.

No one can read this work without noticing the firm but gentle (the latter word used in its highest sense) manner in which the opinions and theories of others are commented on; the liberal spirit in which the works of contemporaneous authors are discussed; in a word, the general "good form" of the whole treatise. Although our own views are in opposition to Dr. Blandford's on many points, we can neither fail to recognise the amount of thought which he has bestowed on these very subjects, nor to acknowledge the potency of many of his arguments—in fact, the world must be a little older before they can be entirely refuted. In the present state of knowledge, the position he takes up as to classification is to some extent unavoidable; it is so in a considerable proportion of cases of insanity. He says: "We are obliged to make two classifications—to lay down abstractedly a pathological classification of insanity; and, on the other, to describe, according to the most prominent and important symptoms, the various patients we have to protect and cure. Classifying not the disorder, but patients, I would reverse the order suggested by the Committee of the Medico-Psychological Association, and note, in the first place, the mental symptoms observable at the time of inspection, and afterwards assign to these their pathological significance, if the history or the symptoms enable us to do so. As in all diseases, the immediate symptoms must direct the immediate treatment, though the pathology will also have an importance which it is hard to over-estimate." To this we cannot subscribe as a principle, although, unhappily, in practice, it must be admitted, circumstances occasionally compel its adoption. Much harm may—nay, is—done by the immediate treatment of prominent symptoms. Take one prominent symptom—acute mania—it may depend on anæmia, hyperæmia, or sympathetic irritation. Before proceeding to immediate treatment, is it not absolutely necessary to determine the pathological inductive condition of the patient? If so, we act not on a symptomatic, but on a pathologico-etiological, classification. Our author takes as an illustration of the fallacy of such a system the distinction between mitral and aortic disease, which, pathologically, may each spring from rheumatic endocarditis, and therefore the division is accidental, and not scientific. This is not a case in point. These diseases of the heart produce asthma and dropsy. Rheumatism may also produce changes in brain-structure; and the changes in brain-structure may manifest themselves by insanity. We begin in both cases with rheumatism: in the one, we go on to heart-disease, and its consequent asthma or dropsy; in the other, to brain-disease, with its consequent insanity. It is the dropsy and the insanity which must be considered together—not the heart-disease and the insanity. Dr. Blandford would not treat dropsy apart from its pathological causation; it would not be the prominent symptom that he would indiscriminately attack; nor would acute mania receive from him medication without strict inquiry, and therefore without pathological classification. The whole tenor of the book, however, is in the direction of pathological, not symptomatic,

treatment. We believe that the author is only withheld from the adoption of etio-pathology as a basis of classification, because he cannot reduce the position to an absolutely logical deduction. He speaks most warmly of Skae's *System of Nosology*, admits its force, and touches kindly on its imperfections. In consequence of this tendency, the directions for treatment are much more sound and definite than we meet with in most books on insanity. The advice to the family physician as to the early treatment of such cases is most valuable; this is followed up by instructions as to the proper legal steps to be followed in case restraint in an asylum should become necessary. Good common sense pervades all his remarks as to artificial feeding, restraint, and hygiene. It is a book to go to when in a difficulty; it leads the professional mind in the right direction as to the nature of the diseases of which it treats. It is fit for the student, and a guide to the general practitioner. If its teachings were more fully indoctrinated, there would be more home-treatment of insanity, and fewer cases of nervous disease consigned to asylums.

## REPORTS AND ANALYSES

IN

### MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### LYNCH'S NEW POISON-BOTTLE.

WE have repeatedly urged the necessity of the general adoption by dispensers of some one of the cheap safety-bottles and inventions which add to the security of persons for whom are prescribed poisonous draughts, liquors, or solutions, for external or internal use. Lynch's

new poison-bottle (171 A, Aldersgate Street, London, E.C.) is one of the simplest, cheapest, and most efficient inventions that we have seen. There are a number of conical projections from the surface of the bottle, so arranged that any one grasping it carelessly in mistake in the dark will "from the nettle danger extract the flower safety".

#### WRIGHT'S ANTISEPTIC SOAPS AND SOLUTIONS.

WE have already spoken favourably of Wright's Coal-tar Soap and Solution of Coal-tar. We have tested them, and can affirm their value as antiseptic, disinfectant, and detergent agents. There is a perceptible improvement in the coal-tar soap now manufactured. It is firm, rather pleasantly scented, and has lost none of its merits as a skin-soap, or for use in the sick-room or hospital ward, or in the medical man's toilette. In our opinion, a medical practitioner, who is frequently compelled to touch surfaces more or less infected, should invariably keep in use some form or other of the soaps now manufactured with coal-tar and its products.

#### ARNOLD'S SURGICAL BAG.

THIS bag is one of those refinements of modern comfort with which the ingenuity of our instrument-makers constantly tempts medical men, to their great convenience and advantage. Of course one has to think how far a certain expenditure can be afforded with the view of preventing the trouble, loss, and discomfort which attend imperfect arrangements, defective fittings, and insufficient supply of instruments. It happens often enough that, owing to the scattering of instruments, to the want of convenience for packing them, or to defects of selection, just the instruments which are wanted at a surgical emergency are out of the way. To all practitioners we may recommend an inspection of the very convenient, well selected, and portable *armamentarium* in Arnold's Surgical Bag.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, SEPTEMBER 16TH, 1871.

### HER MAJESTY'S HEALTH.

THE brief reports in the *Court Circular*, indicating the somewhat protracted and very severe indisposition of the Queen, have been read with loyal sympathy and vague anxiety. Her Majesty has, indeed, passed through a trying and severe illness, from which she is now happily recovering. At the outset, Her Majesty suffered, early in August, when at Osborne, from dislike of food, disturbance of rest, headache, general *malaise*, and slight inflammation of the tonsil. The latter local trouble soon subsided; but the heat of Osborne and of Windsor proved very trying to the Queen, and she did not satisfactorily recover her general health. The journey north was, however, borne well, and Her Majesty slept better on the road than for several nights previously. On the 19th, and for some days subsequently, the Queen suffered from very severe sore-throat, interfering both with speech and with power of swallowing. As the throat improved, the Queen began to experience pain and swelling a little below the right arm; the general health suffered severely, and for days Her Majesty was unable to take any food. On September 4th, Mr. Lister opened an abscess at the seat of swelling; it was of considerable size, but the subsequent progress was favourable. The improvement in Her Majesty's health during the past three days has been very decided. But, although it is with heartfelt satisfaction that we are able to state that Her Majesty is now believed to be in the path of complete recovery—an announcement which will be everywhere received with sympathetic and loyal pleasure—it must be remembered that convalescence from so severe a form of illness must be somewhat tedious, and that some time must necessarily elapse before the Queen can be as well as she was earlier in the year.

In consequence of the improved health of the Prince Leopold, the constant attendance of a medical man on his Royal Highness was no longer necessary, and Dr. Poore resigned his charge. But, as the Queen desired, for herself and the royal household generally, to have a medical man constantly in the Palace, to attend to cases of emergency, her Majesty has appointed Dr. Marshall of Crathie to be resident medical attendant to her Majesty and the royal household, wherever the Court may be. Dr. Marshall came into residence when the Queen reached Balmoral on August 16, and was in attendance on the Queen, with Sir William Jenner and Mr. Lister, during her Majesty's late severe illness. The appointment of Dr. Marshall will not interfere with the duties hitherto performed by Dr. Hoffmeister at Osborne, or Drs. Ellison and Fairbank at Windsor.

### STUDIES IN CONTAGION.

THE Thirtieth Report of the Medical Officer of the Privy Council contains the results of a very able and interesting research by Dr. Burdon Sanderson under the above title. An abstract of the paper was read at the late meeting of the British Association in Edinburgh by Dr. Ferrier, who was associated with Dr. Sanderson in the inquiry. The object of the inquiry, which is a continuation of that contained in Dr.

Sanderson's previous Report on the Intimate Pathology of Contagion, "is to examine into the origin, growth, and development of microzymes; to investigate the conditions which are fatal or favourable to their existence in the liquid and gaseous fluids by which we are surrounded, in the hope that by doing so we may be enabled to approach one degree nearer to an understanding of their influence on the processes which go on in the living body."

In reference to the origin of microzymes, the question of "spontaneous generation" comes up. The Report, however, does not profess to deal with the general question, but gives convincing proof that in the liquids which were used as tests for the presence of microzymes in the media in which they are supposed to exist (with special reference to Hallier and Béchamp), no spontaneous evolution of bacteria ever takes place, although the question of the evolution of torula in these fluids is not determined by the experiment. Before proceeding to describe the experiments and the methods adopted, the Report gives a short account of the characters of bacteria or microzymes, and the views entertained as to their nature, origin, and relation to other organic forms. Hallier, as is known, considers them as the beginning and end of a genetic cycle or chain; i.e., they develop into higher fungus-forms, and proceed from them again. In the body of the Report, reasons are assigned for the belief that bacteria are well defined independent organisms, and that there is no developmental connexion between bacteria and torula or other fungal forms, their apparent connexion being merely one of juxtaposition. This is opposed to the view put forward by Professor Huxley, that bacteria may be produced as out-growths from torula.

The characters of bacteria, the viscous scum in which they grow, and their method of multiplication, are all described. The most important facts as regards their action on the liquids in which they grow are: "1. That their growth is attended with absorption of oxygen and discharge of carbonic acid; 2. That they are remarkably independent of the chemical constitution of the medium, provided that they are supplied with oxygen; 3. That they take nitrogen from almost any source which contains it, and use it for the building up of their own protoplasm. It is this last power which specially indicates what may be called their place in Nature as the universal destroyer of nitrogenous substances, acting as the pioneers, if not the producers, of putrefaction. They exercise this function, not by virtue of any special relation of their own nutritive processes to putrefaction as such, but simply by their extraordinary power of seizing on the elements which they require for the construction of their own bodies."

The question how far bacteria are the cause of putrefaction is elucidated by numerous experiments, which show that, so long as "the germinal matter" of microzymes is excluded, animal fluids or tissues withstand decomposition for very long periods; while the slightest contact with media containing this material at once determines septic changes. On this subject, however, it may be observed, that the use here of the phrase "germinal matter," is a quasi-begging of the matter in dispute—which is, whether microzymes may or may not arise without "germinal matter." It is not asserted that putrefaction is caused by bacteria only, as the facts do not afford sufficient grounds for drawing such a wide conclusion.

The experimental results are stated under three headings, according as they relate to the conditions which limit the evolution of organic forms, and particularly microzymes, in test-liquids; to their distribution in ordinary water and in most substances; and, lastly, to their occurrence in the tissues and liquids of the animal body. The method adopted in reference to the first consideration was to enclose the test-liquids in capillary superheated tubes in such a way as to avoid all external contamination. The liquids used were Pasteur's solution and albuminous liquids, such as serum. As the result of numerous experiments, it was found that in all these tubes organisms appeared if the liquids had not been heated. It was found, on the other hand, that no evolution of organisms takes place in the same liquids when boiled or superheated, whether they are kept at the ordinary temperature or

that of the body; and that the effect is not modified either by the tension of the air or by its quantity as compared with that of the liquid.

The occurrence of organisms in these liquids is entirely due to introduction from without. There are two great sources of contamination—the air; and water, or contact with moist substances. The most interesting and perhaps most important part of the Report is that which traces to their primary source the various forms which spring up so readily in organic liquids. While the various fungal forms (commonly *torula* and *penicillium*) are derived chiefly from the air, the germs of bacteria exist almost exclusively in water, and adherent to apparently dry but really moist surfaces. Thorough desiccation without great heat is fatal to bacteria; and it would appear that bacteria germs can only exist in the air in the living state in exceptionally moist conditions of that medium. The slightest contact of organic solutions with moist surfaces, or the admixture of the minutest drop of water in ordinary use, is sufficient to determine the appearance of myriads of bacteria.

This property of determining the development of organic forms in a test-solution is called the *zymotic power* of water. The only water which was found not to possess this power was freshly distilled water received in superheated vessels from the condensing apparatus, previously heated to a high temperature by a thorough steaming out. Ordinary distilled water, as contained in laboratory receptacles, as well as undistilled water in ordinary use, possess the zymotic power in a high degree.

The bacteria-germs, it is stated, are quite invisible to the highest powers of the microscope; and even water obtained by the fusion of the purest ice, and approaching the standard of optical purity so nearly that the electric beam, in passing through it, displays a blue colour, is found to be as zymotic as many other varieties of water which in the beam are seen to be full of light-scattering particles. There is here, however, still the assumption that “zymotic” power is related only to the presence of “germs,” and not perhaps of mere dead particles—as Liebig and his school maintain.

A practical method is given whereby to determine the zymotic power of different kinds of water. It consists in adding to a quantity of boiled Pasteur's solution, contained in a superheated *eprouvette*, a small quantity of the water in question—in the proportion of one drop of the water to each cubic *centimètre* of the solution. An unimpregnated *eprouvette* is placed side by side for comparison. At the end of a week, the impregnated *eprouvette* becomes hazy or opalescent from the enormous development of bacteria. Distinct degrees of opalescence can be readily detected in the various *eprouvettes* impregnated with specimens of different waters. A comparative analysis of the amount of *living* organic matter contained in the water supplied by several of the metropolitan water companies was instituted; and it was so far satisfactory, that different degrees of zymotic power could be established. Further than the fact that filtration has no perceptible effect on the zymotic power of water, no conclusions are based on the experiments. That this method may lead to very important practical purposes, we have no doubt. A series of experiments was made to determine in how far the zymotic properties of water are affected by chemical compounds which are believed to have the power of arresting the evolution of living germs in organic liquids.

Water through which ozone was passed for some time was found to have entirely lost its zymotic properties. On exposure to air, *penicillium* grew luxuriantly, but no bacteria. The same result was obtained with water rendered pink by Condyl's fluid. Carbolic acid in the proportion of 0.1 per cent. does not destroy the zymotic power. In the proportion of 0.5 per cent in these fluids, it is stated entirely to prevent the development of bacteria, but not of *torula* or *penicillium*. A similar result was obtained with sulphate of quinia in the same proportion. This is a result somewhat different from those obtained by Binz.

Peroxide of hydrogen, and also chlorine, are likewise fatal to bacteria. These results are very valuable, as they seem to show that precisely those substances which are known as antiseptics exercise their power by their fatal effect on bacteria life. In connexion with this, the experi-

ments related under the third heading—viz., the circumstances which determine the existence of microzymes in liquids and tissues of the body—are of extreme interest. It might naturally be supposed that from the continual contact of the body with media containing the germs of bacteria, and their introduction into the stomach with ordinary water, these organisms might find their way into, and pervade, the tissues and liquids of the body.

The most careful experiments with blood, however, show that it does not contain bacteria, either actually or potentially; and, moreover, that when received with due precautions in superheated vessels direct from the artery, it does not become putrid even when exposed to the air, although the surface may become covered with *penicillium*. The addition of one drop of zymotic water is, however, sufficient to determine an immense growth of bacteria, and with them the signs of putrefaction. A precisely similar result was obtained with muscle and animal tissues generally. In all cases, putrefaction was traceable to the admixture with water or contact with unheated surfaces. Urine apparently owes its decomposition entirely to the development of bacteria and other organisms from external contamination.

Pus obtained from a deep-seated abscess did not contain bacteria germs, and did not decompose till water was added. On the other hand, pus obtained from a pyæmic abscess was found to teem with bacteria. From this may be made a deduction of such considerable importance that further experiments, we trust, will be communicated. Its precise relation to practical surgery seems to us, however, doubtful.

Of immense practical import likewise are the conclusions drawn from certain experiments in reference to the decomposition of milk. The experiments show that the decomposition of this secretion proceeds *pari passu* with the development of bacteria derived entirely from contamination with water or impure surfaces.

Such are the chief results of a most careful and laborious investigation, which will serve to explain many hitherto obscure facts in relation to the theory of spontaneous generation, and, what is of more importance, the whole question of putrefaction and its relation to antiseptics. Hallier's doctrine of micrococcus has been severely shaken by these researches, and with it “the whole superstructure he has so ingeniously and laboriously built on it.”

#### SANITARY MATTERS IN DUBLIN.

A DOCTOR'S holiday is often another name for work in disguise; and just as Dr. Lankester, last year, taking his holiday at St. Helier's, poked his nose into all the dirty places of the town, analysed the drinking-waters, harangued the people at a lecture at the town hall, and made himself generally extremely useful and disagreeable, so Mr. Benson Baker, deserting the beautiful scenery of the Tamar, and thinking scorn of the Mên-an-Tol and the rocking-stone, went straight from the Plymouth meeting of the British Medical Association, and plunged into the purlieus of Dublin. To the “wild scenery of Zennor”, he preferred the back-slums of a populous city; and for otter-hunts on the Lynher, he substituted a perquisition into the fever-haunts and diseased meat markets of the metropolis of Ireland. We have had much to say to our readers lately of the excellent system of curative public medicine which is organised in the sister kingdom under the Irish Poor-law. They are, through us, familiar with the merits of the Irish dispensary system, its excellent organisation, the zeal and efficiency with which it is worked, the facilities which it affords for the quick and economical treatment of the poor; the extent to which it has favoured efficient vaccination, relieved the sick, and lightened the rates by reducing the general average of zymotic, or preventable, sickness throughout the kingdom. The faults in that system are, the facility with which tickets are granted, and the consequent abuse of the public

funds by undeserving persons; and the insufficient remuneration of the medical officers who work under it. As a whole, it is considerably in advance of our own Poor-law system.

There was reason to hope that we might also find something to imitate in the general sanitary administration on the other side of the channel. The admirable organisation of the Poor-law medical officers offers great facilities for a complete system of protection against preventable diseases by a scheme of sanitary administration, which should attribute prophylactic health-functions to the dispensary physicians. Mr. Baker, in studying the details of the two systems together, appears to have entertained these anticipations. They were not, however, fulfilled. Mr. Baker declared the result of his voluntary visitations in some letters addressed to the Dublin papers; and, in another part of our columns, he gives further details. His object in all this was, to declare to the Dublin corporation the impressions produced upon a new and independent observer, looking with unprejudiced eyes upon the arrangements which they make for the health and physical safety of their citizens; in the hope that such a public declaration may prove of service to those who at present suffer from the neglect of that body. He found the scavenging of the streets abominably neglected: the refuse of houses thrown into the public ways, and largely left there to fester and poison the air; so much of it as is removed, he describes as deposited on great heaps in the most populous parts of the city. This system of cess-poisoning is carried out at an expense, for the last year to the citizens of Dublin of £51,378. The sewers are neither ventilated nor flushed: a hundred million gallons per day of Vartry water are allowed to overflow by the bye-wash, which, it is suggested, might be used for flushing the sewers, and other sanitary purposes. The Liffey, which receives the outfall of the sewers, and runs past a number of important public buildings, and through the heart of the city, is little better than a seething ditch. The tenement-houses, which are kept cleanly enough by the poor people who live in them, are poisoned by filthy yards and cess-pools, "which baffle description". Fever—always a test of the state of soil, air, and water—is endemic in Dublin. There is only one fever-cab connected with the sixteen Dublin hospitals. "It is not an uncommon thing," says Mr. Baker, "to see all kinds of fever taken through the streets without the slightest precaution, in ordinary cabs and cars." He saw a patient suffering with small-pox being drawn through the streets, at noon, on a greengrocer's barrow, surrounded by the sorrowing members of her family. There is a disinfecting apparatus provided by the corporation, but it was afflicted, when seen by Mr. Baker, with a hole in the pipe, so that the disinfecting chamber is loaded with smoke and soot. The articles to be disinfected are brought in cabs and cars. Ten people had used it in the course of a month: according to the published statistics, it should have been used by little less than a thousand. On the whole, such an apparatus, so used, by giving a sham feeling of security to the city, is rather a public evil than a public good. The cholera arrangements are described as on a similar scale of efficiency. If cholera be discovered in a ship, the patient is to be brought, as best he can, on shore, and conveyed by the nearest cab to a hospital situated in a fashionable part of the city.

Dr. Mapother, the able corporation health-officer, makes some qualifying statements in our columns to-day, to which due weight will of course be attached; but, on the whole, Mr. Baker has evidently hit some very weak points in the administration of the city of Dublin. We feel sure that an improving sanitarian from Dublin might make an exposure not less damaging of the state of things in some parts of London. We invite our fellow citizens from Dublin to the useful task. But we feel certain that no inhabitant of Dublin will feel satisfied at being unnecessarily infected, diseased, and killed, on the sole ground that other people in other places are treated with no less unjustifiable neglect. They will rather, we think, be inclined to thank Mr. Baker for his labour and honesty of speech, and to take into their own hands the much needed sanitary reform of their city.

## ELECTRO-PUNCTURE OF THE HEART IN APPARENT DEATH FROM CHLOROFORM.

THE means at our disposal for the restoration of persons in whom life is endangered while they are under the influence of anæsthetics, are not so certain of success that we can afford to rest content with them. For this reason, we here place before our readers an abstract of a very interesting paper on Electro-puncture of the Heart as a restorative measure in chloroform-syncope, published in the last number of Langenbeck's *Archiv für Klinische Chirurgie*, by Dr. Steiner of Vienna. It will be seen that the author of the paper does not assert that electro-puncture is an absolutely infallible remedy; but he produces sufficient evidence in favour of the innocuity, and at least occasional success of the operation, to entitle it to consideration.

Dr. Steiner, after some preliminary remarks, quotes a number of cases from various authors to show that, while in some instances punctured wound of the heart, even by so small an instrument as a needle, has been followed by death, in others the injuries have been recovered from, the article by which the lesion was inflicted having been sometimes found in the wall of the heart after death from some independent disease several years afterwards.

To ascertain by direct experiment the effect of puncture of the heart, Dr. Steiner introduced needles into the hearts of various animals—namely, horses, an ass, dogs, cats, and rabbits. The results of fourteen experiments of this kind have led Dr. Steiner to conclude that puncture of the ventricular wall with a needle is not attended with danger, provided that the instrument be at once removed. If allowed to remain, or moved to and fro, it may produce fatal inflammation, or laceration of the muscular substance. Puncture of an auricle or of a coronary artery, is followed by continuous and fatal hæmorrhage; though there is just a possibility that the hæmorrhage from the artery may be arrested by the formation of a plug. If the needle penetrate the endocardium, the contractions of the heart may in one or two minutes produce such an amount of laceration of the muscular fibre as to lead to rupture of the heart at this point. The careful temporary introduction of a needle into the substance of the heart is, then, not necessarily dangerous.

Turning, next, to the subject of galvanism, Dr. Steiner observes that in two recorded cases of chloroform-poisoning attempts were made to excite the heart's action by the galvanic current. They were, however, both unsuccessful; the remedy not having been applied until all other usual means had failed. No conclusion, therefore, as to the effect of galvanism on the heart could be drawn from them.

The principal objections raised against electro-puncture of the heart are, first, that it may do harm by cauterising; and, secondly, that it may give rise to a dangerous development of gas. Dr. Steiner has found that these objections are without weight in regard to a weak interrupted current—which is all that should be used for the purpose of resuscitation. Even after passing a continuous current for a quarter of an hour into hearts filled with blood, there was only a very slight extrication of gas by the electrolytic action of the battery. The caustic effect he found to be practically nil.

In his experiments on animals narcotised by chloroform, Dr. Steiner found the most useful instrument to be a single-celled Smee's battery with an induction apparatus. The needle was introduced before the full effect of the chloroform was produced; and in this way the arrest of the heart's action was at once indicated by the cessation of the movements of the needle. Of the experiments performed, six were successful, and ten unsuccessful. In seven other cases, artificial respiration failed to restore the animals.

The conclusions at which Dr. Steiner has arrived from his experiments are the following.

Electro-puncture of the heart is not dangerous. In cases of arrest of the heart's action by chloroform, even the immediate application of electro-puncture to the heart is not a certain means of resuscitation. The cause of this lies in the rapidity with which the heart loses its irritability after arrest of its action; and this occurs sooner under the in-

fluence of chloroform than in ordinary circumstances. The immediate application of galvanism to the heart is to be preferred to artificial respiration, in all cases where the cessation of the pulse at the wrist and the apparently fatal collapse indicate the total failure of the heart's action. The success which has in some cases attended artificial respiration is probably to be explained partly by the circumstance that the heart's action had not altogether ceased, and partly by the heart having been irritated during the progress of artificial respiration. In applying electro-puncture, the positive pole should be applied to the needle introduced into the heart, and the negative at the scrobiculus cordis or over the seventh intercostal space on the left side. The current should be weak, and should be interrupted every few seconds. Galvanism of the heart applied in this way is not only relatively the most powerful means of rousing the action of the organ, but it also materially favours the inspiratory movements. The reappearance of movements in the needle or of those of respiration, and the return of the pulse at the wrist, are not sufficient indications for ceasing to apply the galvanic current; it must be continued until the heart acts rhythmically and vigorously. When commencing recovery, however, is indicated by the above mentioned signs, artificial respiration may be employed at the same time with electro-puncture, so as to afford the heart the additional stimulus of a supply of oxidised blood. If no result follow the application of electro-puncture for a period of fifteen minutes, it may be concluded that the irritability of the heart is entirely lost, and that all further attempt at resuscitation will be useless.

The cases, says Dr. Steiner, in which electro-puncture of the heart should be applied, are those in which there is profound syncope with rapid collapse; the pulse becoming immediately imperceptible, and the eyelids fallen.

A SERIOUS charge of cruelty towards one of the inmates of the Wandsworth County Lunatic Asylum has been preferred.

THE Midland Counties Idiot Asylum at Knowle will benefit to the amount of £1,350 by the bazaar held in Birmingham last week.

THE Board of Guardians of Manchester, having instituted a house-to-house visitation, discovered 2,094 unvaccinated children, of whom 1,187 were over the age at which vaccination can be enforced.

AT a Sheriff's Court held at Winslow, Bucks, Mr. R. De'Ath, surgeon, of Buckingham, was elected Coroner for the northern division of the county of Bucks.

MR. LORIMER, being about to leave Welshpool for Farnham, has been entertained by his friends at a public dinner in the former town.

DR. W. HOME, V.C., C.B., Deputy Inspector-General of Hospitals, retired on half-pay, recently appointed a Medical Inspector of the Privy Council, has this week been gazetted to the honorary rank of Inspector-General.

THE existence of yellow fever, "to a limited extent", in Charleston, is announced by the Medical Society of that city. The first case occurred on the 27th of July, and in the following four weeks there were thirty-five cases, and nine deaths.

THE Town Council of Dudley are aggrieved by a valuable, but severe, report by Dr. Thorne Thorne concerning the sanitary condition of the town; but the *Birmingham Morning News* mildly remarks, "the sanitary state of Dudley is certainly in need of improvement." Dr. Thorne's reports have always proved excellent and reliable.

KING'S COLLEGE HOSPITAL has just undergone the process of a thorough cleansing, painting, and redecorating, throughout all the wards. The Board decided to close the hospital until the 16th instant, so far as the admission of fresh out-patients is concerned. All accidents and urgent cases, however, were admitted as usual.

THE Paris death-roll for the week ending September 9th includes thirty-five deaths from dysentery, ninety-one from diarrhoea, thirty-six from cholera, and four from cholera.

THE current numbers of the *Edinburgh* and *Quarterly Reviews* contain each an interesting article on Mr. Darwin's late work. That in the *Quarterly* is particularly able and well reasoned, and is evidently from the pen of an accomplished and thorough zoologist.

THE fifteenth annual meeting of Hungarian physicians and naturalists has lately been held in Arad, commencing on August 28th, and terminating on September 2nd. Dr. Poor, one of the vice-presidents, occupied the chair; the Archduke Joseph, who had been elected president, being closely occupied with the organisation of the Hungarian army. During the meeting, a donation of 1000 florins was received from Dr. Poor, and another of 1500 florins from the widow of Dr. Flor, to serve as the foundation of a pension-fund for medical men and their widows.

#### THE PRESTON CASE.

WE hope no more will be heard of the "fasting girl" of Preston. She is, in fact, a well-nourished woman of thirty, who takes food like other people, and thrives on it. The friends have admitted as much to Dr. Marshall, and we have other evidence of it—if any were needed. There are still fools in abundance who flock to the place and are willing to pay for seeing a recumbent woman, about whom has been raised a cheap and lucrative halo of imposture.

#### PUBLIC SWIMMING BATHS.

AS we are all agreed that something more ought to be done for providing proper bathing-places for our thickly gathered and great unwashed population, will not some one now take the trouble of going through the process of calling a meeting, forming an association, and appointing a committee, who shall utilise and direct the force of public opinion, and bring the subject deliberately and successively under the notice of the central and local authorities, and work till the object is achieved? An association and a public meeting is now the *obligé* antecedent of every useful piece of legislative or executive progress. Never did any nation live so essentially under government by public meeting.

#### MEDICINE IN RUSSIA.

ACCORDING to the official reports for 1870, there were in that year 10,000 legally qualified medical practitioners in Russia; of whom 6113 held public appointments, and 4686 were engaged in private practice. There is about one medical man to each 7182 of the population. Among the lower classes, the value of rational professional assistance is quite unrecognised; and hence infectious diseases commit frightful ravages, and the mortality among children is greater than in any of the countries of western Europe.

#### DOMESTIC WATER-STORAGE.

MR. H. E. TRESTRAL of Harston urges us to draw attention to the fact that in thousands of houses in many of our large towns and cities, the cistern is in the water-closet. In all such places there are noxious gases; and the water in the cisterns becomes impregnated with them according to the length of time it remains before being drawn off, and to the extent to which these cisterns are shut off from the closet-compartment. In Glasgow, for instance, in hundreds of houses the cisterns are not at all covered in, and the continual dripping from the feeding-pipe rather tends to increase the amount of noxious gases taken into the water of the cistern by exposing a fresh surface continually. That such gases are absorbed, has been abundantly proved. If, for instance, after the water has been in one of these cisterns all night, a tumblerful be taken, any one with the ordinary sense of smell can detect the water-closet effluvia in it. "And the other day," says our correspondent, "whilst staying at Yarmouth, a lady complained to me that she could not use the water to clean her teeth in the morning; 'it

was so disagreeable." Now that we hear so much of cholera and diarrhoea, these remarks are timely; and it is a pity that more suitable places are not found for placing drinking-water cisterns.

#### WESTMINSTER HOSPITAL.

It is stated that the site of Westminster Hospital has been claimed by the Government, and that it will be necessary for that hospital either to resign its being and hand over its work to its big brothers, St. Thomas and St. George, which now occupy the districts on each side of the water, or to migrate in search of a *raison d'être* and a place for standing. It is suggested that both may be found at Chelsea Hospital and that the pensioners should be dispersed as their brethren at Greenwich were.

#### THE "MEDICAL DIRECTORY."

WE are glad to learn that no qualifications will be inserted in the forthcoming edition of the *Medical Directory* which cannot be registered under the Medical Act. The returns which have been made to the editors during the past few weeks show a considerable increase in the number of foreign degrees obtained without residence; and as these confer no right to practise, and cannot be registered in this country, the editors have decided not to insert them. Actual registration is not a condition of insertion in the *Medical Directory*, but the qualifications must be such as the registrars would receive. This is a very sound and judicious arrangement.

#### DISINFECTANTS.

DR. SAMUEL R. PERCY, Professor of Materia Medica in New York, who has been spending some time in this country, writes to the public papers, *à propos* of cholera, to urge the extensive use of chloralum as a harmless, inodorous, and effective disinfectant, in all parts of a house, and for drains and out-door purposes. He says: "With such an agent as chloralum, possessing the active properties of hydrochloric acid, it is possible effectually to disinfect; and wherever offensive matter exists, especially in the sick-room, this agent should be used. I especially advocate chloralum, because not only is its power known to me, but, in my opinion, it has no substitute." Dr. Hardwicke also loses no public opportunity of urging the uses of this antiseptic.

#### POISONING BY ABSORPTION OF BICHLORIDE OF MERCURY.

AN inquest has been held at Bath on a child of Mr. Fowler, M.P., aged nine years, who has died from the absorption of bichloride of mercury once applied locally in the well known caustic solution of ten grains to the drachm, for the cure of ringworm, by Dr. Meeres of Melksham. The application is one which has long been most extensively used for the destruction of *navi*, and as a topical parasiticide. It is recommended in the text-books, and has been used innocuously and with great benefit in probably many thousand cases. There appears in this case to have been an unusual susceptibility. The substance was absorbed, and the poor child died with symptoms of mercurial poisoning. The jury attributed—most unjustly—blame to the surgeon in their verdict. In the circumstances, every one will sympathise with the sad loss of the relatives. Occurrences so distressing are only less shocking to the medical attendant. To the pain which they give, so unjust a verdict adds a further acute pang, and inflicts a serious and most undeserved injury. Dr. Meeres has our sincerest sympathy, and we protest against the injustice done to him.

#### PROPOSED MEDICAL ASSOCIATION IN SPAIN.

THE advantages of combination among members of the medical profession are, we are glad to observe, beginning to be perceived by our confrères in Spain and Portugal. In the former country, it is proposed to form a "Medico-Pharmaceutical Association", to which all physicians, surgeons, and pharmacists are to be admissible on expressing in writing their desire to become members and their intention to submit to the rules in force for the time being. The object of the Association is stated to be the improvement of the material interests and the elevation of the moral and scientific condition of its members. The Association is to be constituted of and managed by a central *junta* in the

capital, a provincial *junta* in the chief town of each province, and a section in each judicial district. The provincial *juntas* are to be independent, provided that the common action of the Association be not interfered with. The disposal of the funds is to be in the hands of the Association from the time of its formation; but the provincial branches are each to have the power of possessing their own funds and disposing of them as they may think fit. The project is supported, we believe, by the whole medical press of Spain; and the *Correio Medico de Lisboa*—a new and highly promising medical journal—speaks strongly in favour of a similar Association being formed in Portugal, urging that the substitution of *esprit de corps* for the *individualism* now prevailing would raise the profession in that country from its state of decadence, and would enable it to gain and maintain that position to which its learning and its services entitle it.

#### STOCKWELL FEVER HOSPITAL.

IN consequence of the comparatively limited number of small-pox cases now occurring, it has been decided to close the Stockwell Hospital, and make preparations for the reception of fever-patients.

#### DEATH UNDER THE INFLUENCE OF AN ANÆSTHETIC.

A RECENT number of the *Oxford Chronicle* reports a fatal case in the Radcliffe Infirmary, Oxford. The patient, a married woman, aged 44, was about to undergo an operation for cancer of the breast. Bichloride of methylene was administered by the dispenser of the infirmary, in the presence of the house-surgeon and one of the surgeons, on a flannel bag. After two or three convulsive gasps, the patient expired. The quantity administered was small. Artificial respiration was practised, and other means of restoration, but without success.

#### PROFESSOR TROUSSEAU ON THE TREATMENT OF DIARRHŒA AND INFANTILE CHOLERA.

DR. BRABAZON, and other of our readers, will thank us for directing attention to the practice of that great clinical authority, the late Professor Trousseau. It will be seen, by reference to the fourth volume of his *Clinical Medicine* recently issued by the new Sydenham Society, that in the treatment of most forms of diarrhœa he employs purgatives, and even saline purgatives, freely, while he strongly condemns the opiate treatment, except in cases of what he calls "nervous diarrhœa," and diarrhœa from "excessive tonicity of the bowel," when he gives opium in small doses, one drop of laudanum to an adult, and a quarter of a drop to an infant. Speaking of infantile cholera, he says (p. 137): "In the cold stage of infantile cholera, purgatives, as well as emetics, are indicated. The purgative which I prefer before all others is the hydrargyrum cum cretâ, etc." Then of opium, in the same class of cases, he says: "I cannot express myself too strongly against this agent. I repeat, that I am not acquainted with one more disastrous in its effects, nor more frequently and more imprudently employed." He repeats (p. 139) that, "in infantile cholera opium in any form ought to be rigorously avoided;" and he recommends in the second or febrile stage of the disease "mild laxatives, such as the neutral salts, but particularly calomel in very small doses." Perhaps the authority of this great empirical physician may have some weight with those who are prejudiced in favour of an opiate and against an evacuant treatment of diarrhœa. We commence to-day the collection of the views of English physicians on the subject.

#### RECONSTITUTION OF THE POOR-LAW BOARD.

THE appointment of Mr. Lambert, C.B., as Secretary of the new Local Government Board (which includes the Poor-law Board, the Medical Department of the Privy Council, and the Local Government Office), will be very acceptable to all who know the great ability and intelligence which he has shown in some of the most important measures of state-medicine. He was the author of a very important report on the Irish dispensary system, and has taken an initiative and leading part in most of the recent improvements in Poor-law administration; and we feel confident that he will have the wisdom to see that the

hope of reducing pauperism is bound up with the prospect of perfecting the curative and preventive organisation of public medicine, and placing the Poor-law medical system on a better footing. The retirement of Mr. Fleming will not be regretted by the Poor-law medical officers. Justly or unjustly, he was credited with stubborn opposition to much that has been done to improve this department of the Poor-law; and he unquestionably assumed a false position of hostility to persons such as those who constituted the Workhouse Infirmary's Association, and who sought for public benefits by legitimate representations. His uncompromising hostility had the useful effect of stimulating them to greater activity. He was an especial thorn in the flesh to some of his colleagues, and to his late chief, Mr. Villiers. To retain his position and maintain his influence, which he did, was in itself an evidence of no small vigour and activity of mind.

#### THE CONTAGIOUS DISEASES ACTS IN INDIA.

THE *Times* correspondent in Calcutta calls attention to a recently published report on the working of the Contagious Diseases Acts in Bombay. It is in favour of Dr. Payne's plan (now adopted in Calcutta) of permitting the women to pass the necessary ordeal at their own homes, on paying the surgeon's costs; only the Bombay Superintendent would pay the inspector a stated salary, and not permit him to receive the fees. The subject is exciting much attention in India. If it could only be discussed dispassionately, some of the real evils of the Acts might easily be removed, but unfortunately it cannot, and the result is, groping about among undoubted evils for a real good. Every report, however, shows that the benefit which has accrued from the Acts has been immense, and there cannot be a doubt that in some form or other they will be maintained. Dr. Payne, who has set on foot the private system, is one of the most high-minded gentlemen in India; but the correspondent does not think that his system will work well till it is based on female, not male, visitations, the latter only being brought to bear on exceptional cases. The subject, he says, is being very earnestly dealt with by Indian medical men, who, as a rule, appear scarcely to comprehend the ground taken by the opponents of the Acts.

#### CHOLERA AT CARDIFF.

FOUR severe and rapidly fatal cases of cholera are reported to have occurred on board an American ship, on her way from Hamburg to Cardiff. All the four cases were fatal within twenty-four hours of seizure. The ship and crew have been quarantined.

#### PREVENTION OF CHOLERA ON THE THAMES.

ACTIVE measures are being taken by the joint local boards, under the guidance of Dr. Buchanan, of the Local Government Board, and Dr. Meymott Tidy, to inspect the shipping in the port of London, and guard against the importation of cholera. The Admiralty have consented to lend the *Rhine* and the old *Dreadnought*—now clear of small-pox convalescents—for cholera and quarantine service. The services of Mr. Harry Leach, of the Seamen's Hospital, will be sought as superintendent and medical adviser of the committee. Mr. Harry Leach's reports on this subject, in the *BRITISH MEDICAL JOURNAL*, have been reprinted. These very able reports have done much to bring about the present organisation, of which they abundantly proved the necessity, and furnished the outline plan.

#### THE MORAL OF RENFORTH'S DEATH.

THE sudden death of Renforth of Newcastle, while rowing an international match, was rendered still more gloomy and tragic by the rumours of poisoning set abroad. They proved to be entirely without foundation. They are none the more likely to be forgotten by the credulous and ignorant public. On the other hand, the disciples of Mr. Wilkie Collins will find in this sad instance a conclusive proof of the mortal dangers of athleticism. The fact is, that such a case as this proves nothing of the sort. Renforth was a man whose constitution was undermined by tropical disorders. He was an epileptic. He was a very excitable man, and rowed under the consciousness of the impending

collapse which his constitutional condition threatened and his medical man prophesied. He never ought to have rowed in a match at all; but his pluck overbore his knowledge of what was due to his weakness. Epileptics of doubtful strength ought not to engage in severe and exciting physical contests. That is the precise moral of this sad affair; but it is one of so little novelty, that it needed not to be pointed by any such tale.

#### THE MEDICAL OFFICER OF ISLINGTON.

AMONG the candidates for the office of Medical Officer of Health to Islington, vacant by the resignation of Dr. Ballard, is Mr. Haviland. Mr. Haviland is well known to our associates as a laborious and very able worker in various branches of public medicine and sanitary science. Especially he is known for his great work on the *Geography of Disease*. Some of his lectures at St. Thomas's Hospital, illustrated by admirable maps, have been laid before our readers. They have attracted universal admiration. We fear that they have been but ill required; and we heartily hope that he may receive in this appointment a fitting acknowledgment of his ability and great services. It will afford him a congenial field for further labour of a kind for which he is admirably fitted.

#### THE WORK OF THE ANGLO-AMERICAN AMBULANCE.

THE illustrious Stromeyer has honoured the work of the Anglo-American Ambulance at Asfeld by translating the report of it, which its surgical chief Mac Cormac published in the *BRITISH MEDICAL JOURNAL*, and has since republished in an interesting and exquisitely illustrated volume. The prologue and epilogue from the pen of the veteran Army Surgeon, are written with the most charming good feeling and warmth of appreciation. His commentaries are of great practical value. Apropos of the admirable work of this ambulance, we may notice some prevalent misconceptions as to its relations, and a little "trouble" which occurred at the outset, and of which some incorrect versions have been recently current in the papers. The ambulance was Anglo-American in constitution of its *personnel* and in its origin; but it was Anglo-French in its equipment at the outset, and wholly English in its finances and supplies through its later stages. The facts are, that Dr. Evans, the dentist of Paris, Chairman of the American Committee, opposed to the utmost the proposition of Drs. Sims, Mac Cormac, Frank, Pratt, Tilghman, and May, to start for the scene of action and join the army. So energetic and effectual was his opposition, that these gentlemen separated themselves entirely from Evans's Committee, and, being thus regularly constituted and supported by the French and English Societies, started, in spite of that gentleman's resistance and independently of his aid, for Sedan. At the last moment, the feeling of annoyance led to a personal *fracas* between Dr. Sims and Dr. Evans, which the latter recently brought before the French police; and, on their declining to take any notice, brought a civil action against Dr. Sims, in which he laid his damages at £200, and received £12. After this premature act of warfare on the part of the chief of the ambulance, they started, unimpeded, for the seat of war, and fortunately reached Sedan in time to render the great services which have reflected lustre on both Societies and on all the *personnel* of the staff, and of which the first act is recorded in the pages to which Stromeyer has paid so high a compliment. The brilliant services of the ambulance at the Loire are as yet practically unrecorded, except in a very brief note in the Report of the British Society just published. It will remain for Dr. T. T. Pratt, the working head of the ambulance there, or for Messrs. Parker, Tilghman, and May, his surgical coadjutors, to give them adequate record.

#### NOBODY'S CHILD.

It will be well that the official inquiry, to be opened next Tuesday by Mr. Henley and Dr. Buchanan of the Local Government Board, into the management of the Small-pox Hospital at Hampstead, should extend beyond the particular cases thus far published. The mysterious disappearance there of a child-patient, of whom all trace has been lost,

s paralleled by the facts of another case which have been authentically laid before us. The parents of a lad of fifteen, who was removed for isolation and treatment, received the afflicting intelligence of his death. They duly prepared for his interment, and followed his coffin to the grave, when the mother received the startling communication that her son was alive and convalescing. Hastening to the hospital, she found—a mistake. She had to be satisfied that her son was really dead. We do not attempt to speak of the gratuitous anguish and alternating mental shocks inflicted on this poor woman. She was one who felt them acutely; and there is no parent in the country who, on hearing her story, will not feel a sympathetic pang. But let that pass. Another somewhat similar history (except that it had a ludicrous ending) comes to us from another of these asylums; and many complaints of inaccurate and imperfect information to friends asking about their sick relatives. Now, in the case of asylums to which patients are removed under the compulsion of a necessary sanitary law, and from which visitors are necessarily excluded, it is peculiarly necessary that the arrangements for giving such information should be efficient and satisfactory. No merits of installation, dietary, or general treatment, will altogether compensate for serious defects in the identification of patients. We are satisfied that inquiry and revision are necessary to save from scandals, under this head, the great metropolitan asylums, which have rendered, and are rendering, inestimable service to the sick poor of London, and whose erection and general administration reflect the greatest honour on the Poor-law Board, and on the many able and public spirited men who have shrunk neither from labour nor from danger in their gratuitous and disinterested services as managers.

## SCOTLAND.

We call attention to the letter of Mr. Annandale in another column, respecting the proposed issue of Parian busts in connexion with the Syme Testimonial.

### MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

AT the meeting of this Society, held on Friday, September 1st, in the Hall of the Faculty of Physicians and Surgeons, the following gentlemen were elected office-bearers for the ensuing session; viz., *President*, Dr. James Adams. *Vice-Presidents*—Dr. James Stewart; Dr. George Buchanan. *Council*—Mr. Torrance, Airdrie; Dr. H. Thomson; Dr. James Gray; Mr. Robert Grieve; Mr. J. Pollock, Mearns; Dr. R. Renfrew; Dr. George Miller; Dr. T. D. Buchanan. *Secretaries*—Dr. Robert Perry; Dr. Alex. Robertson. *Treasurer*, Dr. H. R. Howat.

## IRELAND.

### THE CURRAGH.

THE state of the Curragh would still seem to require some improvement; and it is to be hoped that, amidst the preoccupation of military manoeuvres elsewhere, the sanitary state of this camp may not be treated with the utter neglect of which there is at present reason to complain. On the occasion of a recent report from the sanitary inspector of the district to the local board, of the accumulations of filth from the Curragh, Major Burrowes said that he could confirm the truth and justice of the complaint. The remedy lay with the Government, "and it was very hard to get the Government to do anything—in fact, the Government would do nothing." The disgusting nuisances complained of have been reported by Major Burrowes and the Hon. Col. Foster, the magistrate at the Curragh, but "no reply has been received." Fever, scarlatina, and other zymotic diseases, are rife in the neighbourhood of the camp. We observe that picketing experiments seem not much more successful at the Curragh than in Berks-shire.

"To show you, gentlemen," said the Chairman, "how the present Government do business, I was informed when at the Curragh the other day that, in forty-eight hours after being put into use, not less than six hundred articles of horse-gear for picketing horses were made smash of. So much for economy."

### AN ALLEGED LUNATIC.

MR. JUSTICE FITZGERALD on Friday last heard in the Consolidated Chamber in Dublin an application in an important lunacy case. A conditional order had been granted for a writ of *habeas corpus* to bring into court the body of Mr. Manders, who was detained at the Farnham House Private Lunatic Asylum, owned by Dr. J. F. Duncan. The Attorney-General applied for an order that Dr. Wilson, the assistant and representative of Dr. Duncan, be ordered to hand over to Mr. Lewis all letters, papers, and documents belonging to Mr. Alfred Manders which were then or at any time had come into his possession. The order for the inspection and copying of the documents was then made. Subsequently Mr. Macdonogh said he had, by a perusal of the affidavits, satisfied his mind that the gentleman's state of mental health had been very much improved, but he was convinced that under a writ of *habeas corpus* he could not be discharged; yet, under the powers of the Act of Parliament, the Inspector of Lunatic Asylums would be at liberty to discharge him. Counsel had therefore agreed that the conditional order for a writ should be discharged and the cause shown allowed, and that the gentleman should be liberated. This arrangement was ratified by the court.

### LUNACY IN IRELAND.

FROM the twentieth report of Drs. Nugent and Hatchell, Inspectors of Lunatic Asylums in Ireland, it appears that the statistics of the year 1870 show an increase in the total number of insane persons in the country as compared with those of the previous year. There was an apparent increase of 347 persons in public asylums, the numbers being—in 1869, 6,316; and in 1870, 6,663. The inspectors also reported the following decreases, viz.:—In private asylums and in gaols, 4; in poorhouses, 153; in Lucan Asylum, 2; and in the Central Asylum for criminal lunatics, 3. The total number of registered lunatics in 1869 was 10,080, and in 1870, 10,266, while the numbers at large were in 1869, 6,579, and in 1870, 6,936, thus showing a net increase of 541. There was only one lunatic confined in gaol at the end of the year. The increase in the number of lunatics in district asylums is natural, and was to be looked for; the accommodation for the classes of insane supported at the public expense having been considerably extended within the last few years, so that these institutions have now, in round numbers, provision for 7,600 lunatics. The diminution observable in poorhouses is accounted for by the numbers of insane persons transferred from them to the various asylums during the year. The term insane is here used in a general sense, and applies, we regret to say, indiscriminately to the idiotic and demented, as well as to the lunatic classes, many of whom, when they become a little troublesome to those in charge of them, are sent to asylums, without any reference to their fitness for treatment in institutions for the insane, or consideration for the additional expenditure entailed upon the district by placing persons in expensive curative establishments who cannot possibly derive any benefit therefrom, and who, with due care and attention, could be very well and suitably provided for in the wards of a poorhouse. The cost of support and maintenance in district lunatic asylums for the year 1870 exceeds that of the preceding year by £10,930, the amounts being respectively, 1869, £140,034 : 10 : 11; 1870, £150,964 : 19 : 9. This increase is caused in the first place, by the additional number of patients to be supported, namely, 347, which, at the average rate of maintenance per head, gives £8,088 : 1 : 6; the actual advance, therefore, in the gross expenditure has been but £2,742 : 7 : 4, and it is fully accounted for by the dearth of provisions and other articles of consumption during the past twelve months. The inspectors also give a report on the condition of each asylum.

## NOTES OF A SANITARY TOUR THROUGH DUBLIN.

### I.

SPENDING this autumn a brief doctor's holiday in Dublin, and being desirous of investigating, for the sake of comparison, the Poor-law and sanitary machinery and arrangements in the metropolis of Ireland, I devoted my time to a personal inspection of the city and suburbs, and to the collection of facts connected therewith. I was induced to make some communications on the result of my observations to the public press of the city; and these have excited some attention and a faint contradiction. It will, I am satisfied, not be useless if I record now, somewhat more in detail, my precise *impressions de voyage*. Strongly predisposed in favour of the admirable Irish Poor-law system and its staff of officers, and warmly attached to many distinguished personal friends in Ireland, I am sure that I shall not be accused of any Saxon prejudice if, in spite of my favourable predispositions, I have to point out some glaring blots in the sanitary administration of Dublin, which reflect, not upon the valuable and indefatigable officers of the city, but upon the faults of the system, and the administration under which they work. It is, of course, far from my intention to hint that other, and perhaps greater, faults and shortcomings may not be pointed out in other great cities; but the Poor-law system of Ireland is so far in advance of that in England, that I hoped to find Public Medicine equally advanced there in its other departments. The *tu quoque* argument may, possibly, be retorted; but, in such a matter as this, it is too pitiful an arm to be used by worthy antagonists, and has no other than a merely dialectic value.

The soubriquet of dear dirty Dublin is a title well earned. The genial and generous hospitality of the Irish is as proverbial as, unhappily, the dirty and unsanitary condition of their metropolis. With some few exceptions, the streets present a disgusting appearance. *It appears to be customary to throw into the streets the refuse from the houses.* This is allowed to accumulate and decompose: hence, in the poorer districts, the air is reeking with foetid exhalations.

The Corporation do not appear to have provided sufficient appliances for keeping the streets in a sanitary condition. For the purpose of washing, cleansing, and scavenging the whole of Dublin, there are only five horse-scrapers, four horse-brooms, thirty-one dust-carts, thirty-five watering-carts, and one roller, which, by-the-by, is useless. A steam roller was recommended three years ago by the city engineer; but it has not yet been obtained. It, therefore, follows that Dublin, with an area of fifteen square miles and 24,000 houses, and a population of 310,565, cannot efficiently keep her streets in a sanitary condition: it is further proposed to reduce the number of horses from seventy-eight to fifty. The rate levied for the repair and cleaning of the streets is two shillings in the pound, and amounts to £51,378 for the current year.

The water-supply to Dublin is abundant, and exceptionally good, affording twenty-five gallons per head daily. This water is brought from the Vartny water-works, a distance of twenty-two miles from the city. The expenditure on the whole of the Vartny water-works amounts to £524,244:15; the water-rate is 1s. 3d. in the pound, and amounts to £46,000 per annum. This, though apparently expensive, is the most truly economical and satisfactory sanitary feature in Dublin. This removes one of the most important factors in the spread of preventable disease, and contributes to the health, comfort, and happiness, of the citizens of Dublin.

The sewers of Dublin are said to be better than they were some years ago. During the past twenty years, the authorities have been engaged in this most necessary work; and it is estimated that another five years will elapse before they are completed. The sewers do not appear to be ventilated; consequently, at the full tide, concentrated noxious gases are driven up the pipes into the houses, to the manifest injury of the health of the inhabitants.

It has been shown that, in sewers that are alternately wet and dry, a slimy substance forms inside the pipes, and is the source of danger; this can be removed by frequent flushings. In few places could this be more efficiently done than in Dublin. From the City Engineer's Report, it appears that "the bye-wash is 300 feet long, and the quantity passed over it down to the river during the last three months (1869) has been enormous. I estimate it would average at least 100,000,000 gallons per day."

There is a double service of conduit-pipes from Stillorgan to the city, one of which might be used to water the streets, flush the sewers,

and mitigate the Liffey nuisance. The condition of the Liffey has in times past received the consideration of the corporation, but nothing has been done. The present Chief Justice of Ireland said, more than a year ago, that he should be unable to continue his sittings unless the nuisance was somewhat abated. The Liffey nuisance is proverbial. A few evenings ago, it formed the subject for one of the most popular comedians of the day to rebuke the powers that be from the stage, to the manifest appreciation of the house. The Four Courts, Poor-law Commission Offices, Custom House and other important public and private establishments are situated on the banks of this seething ditch, to the manifest injury of the health of thousands of *employés*. The sewers rate is fourpence in the pound, and yields £8,000 *per annum*.

The houses in Dublin of the wealthier classes are, with the exception of the difficulty in keeping out the sewer-gases, in a sanitary condition. Those inhabited by the poorer classes are generally farmed out, and known as tenement houses. The rental is high when compared with the rental of houses in better streets; the weekly payment for each room averaging from 1s. 6d. to 4s. Thus houses that appear in the valuation list as being rated at £30 *per annum*, realise when let in tenements over £80; for which sum an elegant house might be rented in one of the best streets in Dublin. The people inhabiting these tenement houses are clean. The staircases, passages, and rooms, are fairly whitewashed, and compare favourably with the rooms of people of a like class in London. The cellars of these houses, as a rule, are not inhabited, but they become the receptacle of accumulated refuse. Waterclosets and dustbins in these houses are unknown; the yards, privies, and cesspools, baffle description: they are frightfully filthy. In some of the yards pigs are kept. The water from the roofs of these houses is not carried off by drains, but allowed to percolate through accumulated filthy refuse into the cellars, and thus noxious gases are diffused through the houses. Under these conditions may it not truly be said, here we have excrement-sodden soil producing excrement-reeking air? Thus is Dublin fully prepared for the reception and rapid multiplication of cholera and fever germs. Under such favourable conditions it is not surprising to learn that fever is endemic in Dublin.

It is worthy of remark, that there is only one fever-cab connected with the sixteen Dublin hospitals. It is not an uncommon thing to see all kinds of fever taken through the streets without the slightest precaution in ordinary cabs and cars. On one occasion I saw a bad case of small-pox drawn through the streets of Dublin on a greengrocer's barrow, accompanied with other members of the family, to the hospital. There is an apparatus for the disinfection of clothing, bedding, etc. It is situated in Marrowbone-lane, built in the corner of a dunghill—one of the dépôts for the accumulated refuse of Dublin. There is a hole in the pipe through which the smoke and soot escape into the disinfecting chamber. This condition has existed for several weeks. The chamber is about thirteen feet square by seven feet high; it is open daily from ten till four. The process of disinfection occupies five hours. There is no vehicle to bring the foul clothes to the apparatus. The articles to be disinfected are, therefore, brought in cabs and cars. Are these public vehicles disinfected, or are they allowed to spread the disease? or does the same cart that brings the foul clothing take back the disinfected clothing, and thus reinfect it? Is not disinfection carried out in this manner a false security? According to the reports, ten people had five hundred articles disinfected in a month. Now, the number of persons suffering from communicable disease during that month would be over 1000, therefore 99 per cent. did not have their things disinfected. It is the duty of the Corporation to find adequate means for the disinfection of bedding and clothing, and to supply one or more covered carts for the conveyance of foul articles through the streets to the disinfecting apparatus. It is a monstrous thing to permit either persons or clothes infected with communicable disease to be carried in public vehicles.

The special arrangements made in the anticipation of cholera are, to say the least, unique. In accordance with the advice of the Privy Council, inspectors have been appointed to examine all suspected ships. Should cholera be discovered, the patient is immediately to be brought on shore as best he can. Then the nearest cab will be impressed to convey him to one or other of the two general hospitals that have arranged to receive cholera patients. These hospitals are so admirably situated, that a cholera focus will be established in the most fashionable parts of the north and south sides of the city. It is also contemplated to erect cholera-sheds in the grounds of another hospital, as in a former visitation of cholera. The danger of introducing and spreading cholera amongst the citizens of Dublin might have been averted by obtaining a government ship and improvising a temporary floating hospital.

BENSON BAKER, District Poor-Law Medical Officer, Honorary Secretary of the English Poor-Law Medical Officers' Association, etc.

## THE CHOLERA.

A MAN died at Atgersdorf near Vienna on the 3rd instant of cholera, after an illness of twelve hours' duration. No case had occurred in Vienna itself on the 9th.

THE Hungarian Minister of the Interior has addressed to the authorities in various localities a circular, directing attention to several real or alleged cases of cholera which had been reported as having occurred at Ofen, Marossék, and other places; and calling for the exercise of the greatest energy and rigour in the promotion of sanitary measures.

### THE CHOLERA IN GERMANY.

FROM Königsberg, under date September 7th, it is announced that the cholera appears to be diminishing in the Baltic provinces. On the 4th instant, 40 persons were seized, of whom 27 died; on the 5th, 17 cases and 15 deaths occurred. Both at Stettin and Danzig only one fatal case had occurred within the last few days; and at Elbing, up to the 5th instant, 69 persons had been taken ill, and 42 had died.

Mr. Archer Burton of Coblenz writes to the *Times*:—"It is true that conditions exist in this country which are considered in England highly favourable to the spread of cholera. For example, houses which are not drained into cesspools are the exception in Germany; but this is not found to be attended with the results we should anticipate with our generally-received theories. From a table quoted by Dr. E. Lankester, in his pamphlet on cholera, the fruit of the researches of a French writer, it appears that while 1 in 130 are attacked by this dire malady in Great Britain, where sanitary questions and regulations are supposed to be well understood, in Germany, where drainage is in its infancy, only 1 in 700 are attacked." We should like to hear something more from Dr. Lankester of these statistics and their interpretations. We should be not a little surprised to find them in any way bear the meaning which Mr. Burton attaches to them.

### THE CHOLERA IN PERSIA.

THE *Levant Herald* has received the following brief note from its *Tabreez* correspondent, dated August 11th:—"The cholera broke out here on the 15th of last month, and has been daily increasing in virulence; the death-rate lately amounted to 240 daily, but is now about 125, if the Persian accounts can be received as authentic. A violent thunderstorm happened in the mountains around *Tabreez* about ten days ago, followed by such an inundation as has never been known hitherto. The destruction of property caused in the bazaars and gardens is estimated at £120,000. We are all, Christians and Mussulmans, camped out in the mountains. All the bazaars are closed; commerce and business of all kinds are at a standstill. The mortality among the soldiers was so great that all the regiments at *Tabreez* were disbanded, and the soldiers allowed to proceed to their villages. There is a quarantine of three days at the Russian and, I believe, the Turkish frontier. The advantage of the former is not very evident, as we hear that *Erivan* is suffering from cholera equally with *Tabreez*."

## ASSOCIATION INTELLIGENCE.

### SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

THE next meeting is appointed to be held at Rochester (at St. Bartholomew's Hospital), on Tuesday, September 26th, at 3.30 P.M.; Dr. BROWN in the Chair.

Papers on clinical subjects by A. W. Nankivell, Esq.; by J. H. Jackson, Esq.; and by Dr. Bell, are promised.

Dinner will be provided at the Bull Hotel at 5.30.

FREDERICK JAMES BROWN, M.D., *Honorary Secretary*,  
Rochester, September 11th, 1871.

### SOUTH MIDLAND BRANCH.

THE next meeting of the above Branch will be held at the Town Hall, Wellingborough, on Tuesday, October 10th, at 2 P.M.

Gentlemen who intend to read papers or cases, are requested to forward the titles of the same forthwith.

J. M. BRYAN, M.D., *Honorary Secretary*,  
Wm. MILES.

Northampton, September 11th, 1871.

### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEDICAL MEETINGS.

A MEETING of the members of the above District will be held at the Castle Hotel, Hastings, on Wednesday, the 27th instant, at 2.30; the chairman to be chosen at the time.

Dinner will be provided at 4 o'clock. Charge 5s., not including wine.

All members of the South Eastern Branch are entitled to attend, and to introduce friends.

As the District Honorary Secretary, Mr. Mudd (being about to leave Uckfield), will resign, it will be necessary to appoint his successor at this meeting.

Gentlemen who wish to make communications to the meeting, are requested to inform me *at once*, in order that a notice thereof may be included in the circular convening the meeting.

G. F. HODGSON, *Hon. Sec. of the South Eastern Branch*.

52, Montpelier Road, Brighton, Sept. 6th, 1871.

### WEST SOMERSET BRANCH.

THE autumnal meeting of the above Branch will be held at the Railway Hotel, Taunton, on Tuesday, October 3rd, at 5 P.M. Dinner on the table at 5.15 punctually. Tickets 3s. 6d. each, exclusive of wine and waiters.

The following resolution was passed at the annual meeting:—"That with a view to obtaining from members of the Branch their opinion, and to this extent, authority on especial points of interest, a notice be sent to each member, at least one month before a general meeting of the Branch, of a question on a medical or allied subject to be proposed by the Council, on which at the said meeting each member will be expected to express his opinion; but having regard to the number of opinions it is sought to elicit, no argument in supporting an opinion shall exceed five minutes in delivery, whether read by the writer, or deputed, or spoken extemporaneously."

The following question has been settled by the Council as the one on which opinions should be now asked:—"Does the application of Carbolic Acid favour the healing of wounds?"

Gentlemen intending to be present at the dinner, or to read papers afterwards, are requested to give notice to the undersigned, so that he may make the necessary arrangements.

W. M. KELLY, M.D., *Honorary Secretary*.

Taunton, September 11th, 1871.

## CORRESPONDENCE.

### SANITARY AFFAIRS IN DUBLIN.

SIR,—Mr. Benson Baker's statements had been reported in the local papers when some of them were quoted in your pages; but as your readers have not seen these papers, I am sure you will allow me to show them how Dublin has been traduced. Mr. Baker states that the means for removal of filth from the streets, and for disposal of sewage, are of the worst kind, disgusting and dangerous. They are not satisfactory, as must be also said of many English towns; but that his description is greatly exaggerated, every member of our Association who has visited Dublin will allow. It should be remembered that we have had, for five years only, Sanitary Acts which have been working beneficially in England for twenty-three years, and that sanitary improvements must be always gradual. Our proportion of poor persons is very large; and our city taxes will have to bear, in the ten years 1864-73, an expenditure of a million on our water-supply and main drainage. Our water-works were constructed by Bateman and Rawlinson, and approved most highly by Bazalgette and Lesseps; but Mr. Baker teaches us that we waste more than half our water by the bye-wash, and that this should be used for watering our streets and flushing our sewers. Not a drop is let off by the bye-wash save during the two wettest winter months, when rain waters and flushes only too plentifully. When required, our streets and sewers are watered and flushed by water containing carbolic acid.

Mr. Baker next tells you that "thirteen thousand of the citizens of Dublin suffer from fever annually, of which nine per cent. die." That this statement quadruples the number appears from the following extract from my report for four weeks ending September 2nd, 1871. "The deaths by fever for each of the past six years have been 492, 480, 309, 256, 241, and 351 respectively. The admissions from city dwellings into the above hospitals (Hardwicke and Cork Street), which receive at least three-fourths of the fever cases which arise, were, during

the same periods, respectively, 3,245, 2,536, 1,841, 1,211, 1,16, and 1,652. The Cork Street lists do not distinguish the various diseases, and a considerable proportion are not contagious; for example, of the 989 admissions recorded in the last report of the Government Hospital Board, 232 were for bronchitis, pneumonia, and rheumatism. A circumstance which heightens Dublin death-rates and fever-rates is, that the returns include about thirteen per cent. of strangers who seek relief in its numerous and famous institutions for the sick poor."

The last Annual Poor-law Report (which Mr. Baker has probably seen, for we are favoured with his investigations on that department) returns for all Ireland's "cases of fever or other contagious diseases in workhouse hospitals and fever hospitals", the figures 13,513, which, by a curious coincidence, closely accords with the round number he inflicts on Dublin.

"The sanitary authorities have not supplied any mode of conveyance of infectious disease to the various hospitals"—because the hospitals had already provided vehicles. To prevent the occasional use of other carriages is impossible.

With regard to the reception of cholera cases from foreign ships, I have always advised a floating hospital; but many great authorities (including Sir D. Corrigan and Dr. Haughton) have counselled otherwise. We are striving to establish sheds for the purpose on a pier in the bay, over a mile from the city. Dublin is so strikingly healthy, and the contagion is still so distant, that I trust they may not be wanted.

I think your readers will agree with your editorial opinion that Mr. Baker's "statistical observations are not without flaw", although they may not award even your faint praise "that they are likely to be found based upon facts." If his statements were true, he would have done more good by reporting them to those who have care of the city, than by alarming our citizens and censuring their medical authorities.

I am, etc., E. D. MAPOTHER.

18, Merrion Square North.

#### THE TORQUAY EXCURSION.

SIR,—As a pendant to your notice of the Torquay Excursion meeting, can you find room for the following verses by my friend, Dr. Evanson?

I am, etc., C. RADCLIFFE HALL.

Derwent House, Torquay, Sept. 11th, 1871.

#### "OUR HOME": A REFLECTION.

Saturday, August 12th, 1871.

Inscribed to DR. BEATTY, of Dublin.

Still was the evening, the scene passing fair,  
And the broad summer lightning illumined the air;—  
But oh! more than all, my old Friend, he was there,

And we sat by the smooth terrace walk,  
And there were two ladies, each genial as bright,  
Whose presence can ever add double delight  
To the brightness of day or the beauty of night,  
And we sing, and we laugh, and we talk.

My Friend and I talk of the old, early times,  
When the days passed all merrily as wedding chimes,  
While he sang his songs, and while I wrote my rhymes,  
In the gay, joyous days of our youth.

And then we reflected, and thought of the past,  
And our looks o'er a long varied lifetime were cast,  
Till we felt how old age stole upon us at last;  
For old men are we both, now, in sooth.

But is spring time, indeed, without any alloy?  
And does summer time never know aught to annoy?  
Is it autumn alone that's divested of joy,

While its harvests wave o'er the rich loam?  
Oh! the autumn has scenes that are grand as sublime;  
And Heaven itself has its own harvest time;  
Be our music, then, sacred,\* and solemn our rhyme,  
As we hasten apace to Our Home.—R. T. E.

#### THE RECENT INQUEST AT BATH.

SIR,—The very sad case of the death of a little child after an application of an alcoholic solution of bichloride of mercury, made by Dr. Meeres for the cure of ringworm, which has been reported in the daily press, is of so much importance that I hope you will allow me to

\* Dr. Beatty is author of an Essay on Sacred Music, and has enjoyed the rare if not unique distinction of having been President of the Royal College of Surgeons, and also President of the Royal College of Physicians in Ireland.

make one or two comments upon it, especially as my name has been mentioned in connexion with the remedy employed.

In the first place, the remedy is not mine: it must have been used many years before I was born. Though I do not use it now, because I like other things better, yet I did use it for about thirteen years very extensively and very freely, painting it lightly over patches of tinea tonsurans. It was, indeed, my usual remedy for ringworm. I have never in a single instance seen any evil result follow its employment. I am confident that in Dr. Meeres's case the patient must have been peculiarly susceptible to the influence of mercury. It is clear that some mercury was absorbed into the system—an occurrence perfectly novel to me under the circumstances. I do not see that Dr. Meeres could have in any way foreseen the exceptional result which took place.

I learn that the child improved the day before its death; and that the latter happened suddenly during fainting, on the child, who had been prostrated by diarrhoea, getting out of bed unassisted to relieve the bowels. This is an element in the case which should not be overlooked in estimating the cause of death.

I do think the verdict most unjust towards Dr. Meeres. It is almost unnecessary for me to add, that these remarks are perfectly consistent with a feeling on my part of the keenest sympathy for the parents of the little child.

I am, etc., TILBURY FOX, M.D. Lond., F.R.C.P.  
Sackville Street, W., September 1871.

#### SYME TESTIMONIAL.

SIR,—The bust of the late Mr. Syme being now completed, it is proposed to have some copies of it made in statuary porcelain. These copies will be one foot in height; and should one hundred be ordered, they can be provided at a cost of one guinea each. Before making arrangements for the preparation of these small busts, I shall be glad to receive the names of any gentlemen who may wish to have one.

I am, etc., THOMAS ANNANDALE.

34, Charlotte Square, Edinburgh.

### UNIVERSITY INTELLIGENCE.

#### UNIVERSITY OF OXFORD.

THE instruction in Natural Science is carried on at the Museum, where there is practical instruction in Physics, Chemistry, and Anatomy and Physiology, together with courses of lectures by the several professors; viz.—Regius Professor of Medicine—H. W. Acland, M.D., LL.D., F.R.S.; Geometry—H. S. Smith, M.A., F.R.S.; Natural Philosophy—Rev. B. Price, M.A., F.R.S.; Experimental Physics—S. Clifton, M.A., F.R.S.; Chemistry—Sir B. C. Brodie, Bart., M.A., F.R.S.; Physiology—G. Rolleston, M.D., F.R.S.; Zoology—J. O. Westwood, M.A., F.L.S.; Geology—J. Phillips, M.A.; Botany—M. Lawson, M.A.; Mineralogy—N. S. Maskelyne, M.A., F.R.S.; Lee's Reader in Anatomy—J. B. Thompson, B.A.; Demonstrator in Anatomy—Charles Robertson, Esq.; Demonstrator of Chemistry, T. H. G. Wyndham, M.A.

Large collections illustrate the several subjects; there is a pathological series, including the collection of Schroeder Van der Kolk, in the medical department, and a medical laboratory. The Radcliffe Library, containing nearly 20,000 scientific volumes, is open to all students daily from ten to four, and on certain evenings during term. There are also lectures and practical instruction in Botany at the Botanical Gardens; and clinical instruction at the Infirmary.

#### UNIVERSITY OF CAMBRIDGE.

THE following courses of lectures will be delivered during the ensuing year.

*Michaelmas, Lent, and Easter Terms.*—Practical Chemistry, by Mr. G. D. Liveing, M., W., F., 1 P.M.—Medical Clinical Lectures, F., 10 A.M.: (Michaelmas) Dr. Paget; (Lent) Dr. Latham; (Easter) Dr. Bradbury.—Surgical-Clinical Lectures, Th., 11 A.M.: (Michaelmas and Lent) Mr. Lestourgeon; (Easter) Dr. Humphry.

*Michaelmas and Lent Terms.*—Zoology and Comparative Anatomy, by Mr. Newton; M., W., F., 1 P.M.—Anatomy and Physiology, by Dr. Humphry; Tu., Th., S., 1 P.M.—Practical Anatomy, by Dr. Humphry and Mr. Carver; M., W., F., 7 P.M.—Practical Histology, under the superintendence of Dr. Humphry.—Pharmacology, by Dr. Fisher and Dr. Latham, Tu., Th., S., 9 A.M.

*Lent and Easter Terms.*—Pathology, by Dr. Bond, M., W., F., 9 A.M.—Chemistry, by Mr. Liveing, M., W., F., 12 noon.

*Michaelmas Term.*—The Laws of Heat, by Mr. Liveing, M., W., F., 12 noon.

**Easter Term.**—Botany, by Mr. Babington, M., Tu., Th., F., 1 P.M.

The dissecting-rooms and museums of anatomy are open daily during the vacations as well as in the terms, and the Professor and demonstrator are in attendance to assist and direct the students. A course of Practical Histology and a course of instruction in Practical Anatomy is given during the long vacation.

The Chemical Laboratory is open daily from 10 A.M. till 6 P.M.; and the professor will attend to give instruction at the times above specified, and at such other times as he may from time to time appoint. The Museum of Materia Medica at Downing College is open daily to all medical students. The physicians will attend at the hospital on Mondays, Wednesdays, Thursdays, and Fridays, for medical instruction, at 10 A.M.; and the surgeons on Tuesdays, Thursdays, Fridays, and Saturdays, at 11 A.M., for surgical instruction.

In order to obtain certificates of attendance on the medical practice and medical clinical lectures, pupils must have attended the physicians' practice three times at least in each week, during term time, inclusive of the clinical lecture, and must also have taken notes of such cases as may be assigned to them by the physician; and for the certificate of attendance on the surgical practice and clinical lectures, pupils must have attended the surgeons' practice three times in each week, inclusive of the clinical lecture. Pupils are recommended to attend the physicians' and the surgeons' practice concurrently.

Opportunities for clinical instruction in mental diseases will be afforded at the County Asylum, Fulbourn, by Dr. Bacon, during the Michaelmas and Lent terms.

Attendance on the lectures on Botany, Chemistry, Materia Medica, Anatomy, Physiology, and Dissections, is recognised by the Royal College of Surgeons of England as a sessional course. Students entered to the practice of the hospital are admitted to the clinical lectures without additional fee.

## OBITUARY.

THOMAS HORNBY, ESQ., POCKLINGTON.

MR. HORNBY, whose death has recently taken place, practised at Pocklington in Yorkshire for nearly sixty years, and was much respected by his friends and patients for his professional skill and moral qualities. He had never missed a meeting of the British Medical Association for many years; and, in his eightieth year and in declining health, could not be dissuaded from attending the meeting at Plymouth. This proved too great an exertion in his feeble state; he returned home in a state of extreme prostration, from which he never rallied.

WILLIAM EGGINTON THOMPSON, M.R.C.S.

MR. THOMPSON died from acute enteric and pulmonary inflammation, after an illness of three weeks, at his residence, Shepherd's Bush, London, on the 5th instant, aged 54. Mr. Thompson was born in 1817, at Stanbrook Hall, near Worcester. He received his medical education at Guy's and St. Thomas's Hospitals. He spent the earlier years of his professional life in practice near his home; but during the last four years he was engaged in practice at Shepherd's Bush, where he had gained a good and rapidly increasing connexion. Mr. Thompson was possessed of sound professional experience and judgment; and his character was that of an amiable, unobtrusive Christian gentleman. As such, his loss is severely felt by his late patients and friends.

CHARLES DUIGAN, L.R.C.P.I.

AFTER a painful illness of three months' duration, this eminent provincial physician died on the 31st ult., at the age of 45. Dr. Duigan was educated at the Richmond Hospital and School of Medicine. He was apprenticed to the late Mr. O'Boine; and took his diploma in 1844 at the early age of nineteen, having shortly before won Sir Henry Marshall's prize for an essay on Dropsy. He at once settled down to country practice as an assistant to his father, who then had the Dispensary of Kinnegad. On his father's death very soon afterwards, he moved into the town of Mullingar, and took on himself the entire charge of his mother and a large family of brothers and sisters. He rapidly rose into practice, and gained the confidence and esteem of all who had the good fortune to engage his services. He lived a most laborious life, never allowing himself any relaxation day or night, and apparently enjoyed excellent health; but his overtaxed constitution suddenly gave way to the disease which for some time was insidiously progressing. His first symptom of failing health was a sudden attack of vomiting

which came on early one morning, apparently without cause. On searching for the cause of this, he was found to have highly albuminous urine; and from that moment the symptoms of uræmic poisoning rapidly and steadily progressed. At length suppression of urine came on, and he died comatose after a long series of uræmic convulsions. Dr. Duigan was Honorary Surgeon to the Westmeath Infirmary.

JAMES DOUGLAS MURRAY, M.B., OF BIRKENHEAD.

JAMES DOUGLAS MURRAY became a matriculated student of Durham University in October 1864, and studied arts there for three terms. In 1865, he entered upon his medical studies in the School of Medicine at Newcastle-upon-Tyne. In June 1869, he passed for Licentiate in Medicine and Master in Surgery at Durham; and in June 1870, he took his degree of M.B. at the same place. During his student's career he obtained a scholarship, a medal, and several prizes. Mr. Murray was in the course of forming a successful and remunerative practice at Birkenhead, but it is believed that its fatigues and responsibilities, preying upon a young frame and an exceedingly nervous temperament, proved too much for his physical strength and his mental equilibrium. He died September 5th, aged 23.

E. S. GREEN, L.R.C.P., SETTLE.

WITH much regret we record the death of Mr. E. S. Green, which took place on the 3rd ult. Mr. Green was the youngest son of the late J. S. Green, Esq., surgeon, of Houghton-le-Spring, Durham. His death was caused by a sad accident. He had ridden to his hay-field; and, anxious to assist his man, as a steep hill had to be ascended, he was attaching an impromptu trace to the horse which he had ridden, so as to connect it to the shafts as a leader, and assist the cart-horse. Having tied the rope to each end of the trace, he was about to fix it, uncured, to the shafts of the cart, when the horse took fright, and started off at a furious pace up the hill, dragging Mr. Green (who was encircled) after him. For a considerable distance, by grasping each side of the rope, he succeeded in keeping his feet. Eventually, however, from exhaustion, he fell, and his foot became entangled. He was in this manner dragged along the road, a distance of a mile and a half, when the runaway horse was stopped. He was immediately conveyed to his residence at Settle. His body was frightfully bruised over the back, hips, and both arms. He lingered for two days. He was attended by Dr. Deighton of Clapham, and Mr. Samuel Hey of Leeds; but all their efforts were of no avail.

His loss is severely felt. In his professional capacity, he was an expert surgeon and a successful operator. He was surgeon in connection with the Settle and Carlisle Railway. He was interred in the burial ground of Ascension Church, Settle. His funeral was attended by a large number of friends; and the shops in the town were closed. A full choral service was given in respect to his memory. He was only twenty-seven years of age, and has left a widow and three daughters.

BRAMLEY WHITTLE, M.R.C.S.

MR. BRAMLEY WHITTLE was born at Croydon in 1809, and was apprenticed to Mr. Dix, at Long Buckby, in Northamptonshire. He was a student at Guy's Hospital, and spent some years at the Paris hospitals. He practised for upwards of thirty years in Norfolk Street, Strand, as a general practitioner. In 1864, he partly retired from practice, residing at Langton, in Dorsetshire; and in 1867, he removed to Sidbury, in East Devon, where he died lately of heart-disease, aged 62.

THOMAS CASEY, M.D.

DR. THOMAS CASEY, whose death took place at St. Albans on August 21st, after a long and painful illness, was born at Cork in 1795. Shortly after his graduation at Edinburgh in 1818, he was appointed Physician to the Dispensary at Cork, where he had commenced practice, and a few years afterwards to the North Infirmary in the same town. In 1840, a serious illness compelled him to leave Ireland and relinquish practice for a time. The Committee of the Infirmary, in gratitude for his seventeen years' services, appointed him Consulting Physician. After a time he was able to recommence practice in St. Albans, where he took an important part in the foundation of the Dispensary (now Hospital), to which he was the first Physician, and which he served for twenty years, until age and illness compelled him to retire from practice. On his resignation, he was appointed Consulting Physician, and presented by the subscribers with a handsome testimonial. He also held the appointment of Consulting Physician to the North Herts Infirmary at Hemel Hempstead from 1846 to 1855.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, September 7th, 1871.

Raines, Charles, Hull  
Rendall, William, Maiden Newton, Dorset

The following gentlemen also on the same day passed their first professional examination.

Davies, Ambrose Lewis, St. Mary's Hospital  
Northey, Gilbert William, St. Thomas's Hospital

## MEDICAL VACANCIES.

The following vacancies are announced:—

APOLLO GLEE AND FRIENDLY SOCIETY, Birmingham—Surgeon.  
ATCHAM UNION, Salop—Medical Officers for the St. Chad's and St. Mary's Districts.  
BIRMINGHAM LYING-IN CHARITY—Two Honorary Surgeons.  
CHARING CROSS HOSPITAL—Assistant Physician.  
CLOCHER UNION, co. Tyrone—Medical Officer for the Aghnacloy Dispensary District.  
COLCHESTER—Certifying Factory Surgeon for District of.  
DUMBARTON—Surgeon to the Prison.  
GAINSBOROUGH DISPENSARY—House-Surgeon.  
GREENWICH UNION—Dispenser.  
ISLINGTON—Medical Officer of Health and Analyst.  
KENT AND CANTERBURY HOSPITAL—Assistant House Surgeon and Dispenser.  
MAGHERAFELT UNION, co. Londonderry—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Bellaghy Dispensary District.  
MANCHESTER ROYAL INFIRMARY—Physician's Assistant.  
MERTHYR TYDFIL UNION—Medical Officer for the Penderyn and Rhigos Districts.  
MIDDLESEX HOSPITAL—Assistant Surgeon; Resident Physician's Assistant.  
MOSTYN COLLIERY FRIENDLY SOCIETY—Medical Officer.  
NORTH DISPENSARY, Liverpool—Honorary Medical Officer.  
NORTHERN HOSPITAL, Liverpool—Physician.  
ORSETT UNION, Essex—Medical Officer for the Grays District.  
POCKLINGTON UNION, Yorkshire—Medical Officer for the Pocklington No. 1 District.  
PORTSEA ISLAND UNION—Medical Officer for the Southsea District.  
QUEEN ADELAIDE DISPENSARY, Bethnal Green—House-Surgeon.  
ROYAL INFIRMARY, Edinburgh—Resident Physician, Clinical Wards.  
ST. SAVIOUR'S UNION, Surrey—Medical Officer for District No. 3.  
SOUTHAMPTON UNION—Medical Officer for District No. 2.  
STOCKPORT INFIRMARY—House-Surgeon.  
TIVERTON UNION, Devon—Medical Officer for the Silvertown District.  
WESTERN GENERAL DISPENSARY, Marylebone Road—Assistant Dispenser.  
WESTMINSTER HOSPITAL—House-Physician.  
WORKSOP DISPENSARY—Resident Surgeon.  
YORK UNION—Medical Officer and Public Vaccinator for District No. 4.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

\*ROGERS, Robert J., Esq., appointed Surgeon to Brighton Police, and Examiner of Lunatics for the Borough Magistrates, *vice* Henry Penfold, Esq., resigned.  
THOMSON, George, M.B., appointed Medical Officer for Braemar, *vice* William Marshall, M.D. Glasg., appointed Medical Officer to Her Majesty's Household at Balmoral.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

## MARRIAGES.

JAY, Frederick Fitzherbert, L.R.C.P. Lond., to Martha Eliza, widow of the late William Lupton, Esq., of Leeds, on September 11th.  
\*VASEY, Charles, Esq., of Cavendish Place, London, to Jane, eldest daughter of William LYNN, M.D., at Brandon Place, West George Street, Glasgow, on September 1st, by the Rev. Dr. Burns of the Cathedral, assisted by the Rev. Dr. Gillan of Inchinnan.—No cards.

**BEQUESTS.**—Mr. Giles Loder (in addition to £5,000 to the Salisbury Infirmary, and legacies to many non-medical charities) bequeathed £2,000 to the Asylum for Idiots; £1,000 each to the Orthopaedic Hospital, Western General Dispensary, St. Mary's Hospital, Paddington, and the Royal Hospital for Incurables; and £500 each to the Royal Medical Benevolent College, the Western Infirmary for Incipient Consumption, Torquay, the Hospital for Consumption, etc., Brompton, and the Cancer Hospital.—Dame Jane Morrison, of Snaresbrook, relict of Sir James William Morrison, bequeathed £500 each to the Hospital for Diseases of the Chest, Victoria Park, and the Dover Infirmary.

DR. WILLIAM MAC EWEN, having been appointed Casualty Surgeon for the Central Police District, Glasgow, has been presented with a complimentary address, a signet ring, and other articles of jewellery, by the officials of the Belvidere Fever Hospital, London Road, Glasgow, as a mark of their appreciation of his services there.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.  
**WEDNESDAY** ..... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
**THURSDAY** ..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.  
**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.  
**SATURDAY** ..... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

To PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

MR. BUSH (Frome).—We have referred the question to Professor Corfield of University College, London.

G. A. P.—A gentleman possessing the M.D. of Pennsylvania or of Otaheite is entitled to call himself Doctor in the present state of the law, whether his degree can be registered or not.

MEDICUS (Leicester) will be able to derive an answer to his question from a perusal of the regulations of the Royal College of Physicians, given in the Educational Number of the JOURNAL. We would refer him specially to the last paragraph of the second column in page 284, and the first column of page 286.

## THE HEART IN DEATH FROM ASPHYXIA.

SIR,—With reference to the condition of the cavities of the heart in death from asphyxia, set down in your reply to "J. F." (Aug. 12th), I beg leave to say that my experience as medical witness to one of the City coroners leads me entirely to concur in the view which you express—"that both sides of the heart are found full, the left less so than the right." In all the cases which I have examined—and I see, perhaps, as much of the pathology of sudden death as most persons—I invariably find the state of heart which you describe to exist, modified more or less as to quantity and quality by the rapidity with which death took place in each subject. Taylor says (p. 773) "that the left side is either empty or with less than the right." I am, etc., R. W. EGAN, L.R.C.S.I., L.R.C.P. Ed.  
Dublin, August 18th, 1871.

ROYAL COLLEGE OF SURGEONS.—The Library and Museum will be re-opened on Monday, October 2nd, on which day the annual registration of metropolitan students will take place, and terminate on Saturday, the 14th.

## KOUMISS.

SIR,—With your permission, I would suggest the correction of an error in your leading article upon "The Geography of Phthisis" in the JOURNAL for September 2nd, 1871.

Institutions for the treatment of disease with koumiss have not yet gone out of fashion in Europe; but, on the contrary, are multiplying yearly. Moreover, the scientific literature of the subject is rapidly increasing in amount and interest. These facts are attested by the catalogues of the Leipzig and St. Petersburg publishers.

In my own knowledge, Stahlberg now conducts an extensive and popular institution at St. Petersburg; and there is another of equally high favour at Warsaw, under the direction of Drs. Przysanski and Nowakowski. At Odessa, Dr. Levinson has charge of an establishment; at Maskau, Dr. Marechti; at Othenstein, near Dresden, Dr. With, jun. In Samara, Berlin, and different parts of Europe, there are other larger and minor institutions, all of which are in high tide of success at present. Moreover, arrangements are now being completed for inaugurating several Koumiss Institutions in the United States.

In England, there is no institution; but here at London a manufactory has been in successful operation for nearly two years, and to this latter many medical men send their prescriptions for koumiss.

In conclusion, my own personal observations and professional experience enable me to say that the good effects of koumiss are not dependent upon locality, for I have never failed to obtain from its proper use here all the great benefits that attend its administration in Tartary.

8, Weymouth Street, September 7th, 1871.

VICTOR JAGIELSKI, M.D.

JENNER'S TEACHINGS.—In order to avoid a formidable correspondence on a matter easily settled, we advise Dr. Davey to communicate with Dr. Seaton, who will no doubt point out the passages to which he refers. This will clear the way for any further remarks which Dr. Davey may wish to offer, and enable him to abbreviate them.

## OBSERVATIONS

ON THE

## RADICAL CURE OF RETROFLEXION OF THE UTERUS.\*

By T. E. BEATTY, M.D., Dublin,

Master S. E. Lying-in Hospital; late President of the Royal College of Surgeons and of the King and Queen's College of Physicians in Ireland; President of the Midwifery Section.

IT is not my intention on the present occasion to enter into any lengthened discussion on the nature and causes of retroflexion of the uterus. I expressed my opinion pretty freely on the subject twenty-four years ago in 1847, in a paper read before the Dublin Obstetrical Society, and subsequently in another communication to the same society in the year 1862, both of which were published at the times of their being read. At the time of my first writing, retroflexion of the uterus was considered a very rare affection. Dr. Ashwell had thus recently expressed himself: "There is no doubt in the profession about the existence of procidentia, inversion, and retroversion of the uterus, but there are many practitioners who question whether the uterus is ever anteverted, anteflexed, or retroflexed." In the course of my paper I detailed several cases that had come under my observation, and expressed my opinions as to the nature, cause, and appropriate treatment, and I concluded with the following:—"In conclusion, I would observe that it is not unlikely these cases are more common than is generally imagined; that the diagnosis from the symptoms and from an examination by the vagina and rectum is not difficult; and that much benefit can be obtained by attention to the pathological condition of the uterus." In the following year—that is, in 1848—the late Sir James Simpson published his first paper upon this subject in the *Dublin Quarterly Journal of Medical Science*. In that paper he says: "With some of the displacements of the unimpregnated uterus practitioners have long been familiar. In particular, the displacements of the organ downwards in the form of prolapsus and procidentia, are recognised and acknowledged by all, and elaborately described in every work on female diseases; but displacements of the unimpregnated uterus in the form of versions or flexions, either of the whole or of the upper part of the uterus, posteriorly, anteriorly, or laterally, have hitherto been looked upon as rare, and this far more, however, from our past want of power of diagnosing them, than from their own infrequency."

From this it is plain that retroflexion of the uterus was considered to be a very rare affection up to the year 1848. But subsequent experience has shown, as I expected, that it is not an uncommon occurrence, but that, as the means of detecting it have been improved, so has its greater frequency been observed. I have spoken of retroflexion all along, as I do not wish to include the subject of retroversion. Sir James Simpson considered them both under the one head; but I think there is quite enough difference between them to entitle them to separate consideration. In retroversion the whole organ is displaced, the fundus coming down, while the os is turned up; but in retroflexion there is little or no displacement of the os; it preserves its natural position, while the fundus is bent down at an acute angle backwards. I am not going to enter into the consideration of the cause or causes of this displacement; but of this I am quite sure, that treatment which will relieve, and even remove the one, will not be sufficient to remove the other, and in retroflexion something more is required than in retroversion to effect a cure. Pessaries of various forms are found to retain the uterus in its position after being replaced by the sound in cases of simple retroversion, and if persevered in for a sufficiently long time, and due attention be paid to the position of the patient, great relief follows. But when the organ has got the vicious bend in retroflexion, I do not believe that any form of pessary in the vagina is capable of rectifying its shape. You may push up the fundus, but you do not thereby straighten the uterus; and the case remains uncured until that is done. Sir James Simpson was aware of this, and he contrived various means of straightening and keeping the uterus straight. His first was the stem with a bulb at the bottom, intended to keep the instrument in the uterus for an indefinite time; but finding that the stem continually slipped out, he contrived the method

of fixing the stem in the uterus by means of a wire-cradle fixed outside over the pubes, and extending down to the perineum, where an arm projected into the vagina, to which the intrauterine stem was rigidly fixed. This, from its fixity, was found not to answer, and it became desirable to contrive means whereby the uterus could be kept straight and yet permitted to have that freedom of motion which is its natural condition. Dr. Moir (*Edinburgh Medical Journal*, 1860) proposed to dilate the os largely by means of sponge-tents gradually increased in size; and having done this, to allow the uterus to contract on wire bougies covered with gutta-percha, these being gradually reduced in size; his object being to allow the uterus to contract very gradually, and to make it contract in such a manner that it at the same time acquired the proper shape. It appeared to me, about the same time, that a simpler mode of proceeding would accomplish the object more easily and perfectly; and having found it to answer my expectations, I published an account of it in my second paper on Retroflexion, in 1862. I will quote a passage from that paper, which will show the principles on which I founded the treatment proposed. "Most commonly there is a certain amount of enlargement, the result of inflammation, which keeps the organ in a state of painful sensibility; and when this is accompanied by ulceration of the cervix, it gives rise to the distressing sensations complained of when the patient stands or walks, and more particularly during the act of defecation, when the contents of the bowels are forced past the tender fundus, displaced and bulging, into the canal of the rectum. Whether this inflammation of the uterus be the cause of the displacement by enlarging the fundus and thus giving it additional weight and tendency to topple over, or whether it is the result of the unnatural and strained position in which the organ is placed by the retroflexion, I will not now stop to discuss. It is enough for my present purpose to state that, the inflammation is at times, and not rarely found to exist, and when it does exist, it should have much influence in modifying the treatment. To attempt to force an inflamed and distorted uterus into its natural shape and position, and to keep it in that restored condition by artificial supports, must only increase the existing inflammation, and, if persevered in, will surely place the life of the patient in great danger. On the other hand, when there is no inflammation of the uterus, or if, when there is, proper means have been adopted to remove it—such as rest, leeches, warm hip-baths, light diet, vaginal injections, direct applications to the ulcers (if any exist), etc.—there is no doubt that the use of mechanical support may be had recourse to with great advantage."

The plan which I then proposed was to rectify the position and shape of the uterus by means of the sound, and then to pass one of Sir James Simpson's uterine stems with the bulb at the bottom, into the cavity of the organ. This, I may say, in passing, is often not easily done; for the sharp bend in the uterus is at times so rigid and permanent, that the instant the sound is withdrawn the organ flies back to its false position, as if with a spring. The stem once introduced, is to remain for at least four or six weeks. But unless it be kept in its place it will fall out. To prevent that, I proposed to insert a flat boxwood pessary into the vagina, upon the smooth surface of which the bulb of the stem would rest, and would move freely over its surface, thus enabling the uterus to change its position as it is accustomed to do, according as the bladder and rectum are filled or emptied, or as the position of the woman is horizontal or perpendicular, while yet the organ is kept quite straight by the stem within. The daily use of a weak astringent wash thrown into the vagina with a syringe would keep the mucous membrane free and healthy, and the woman from the first day might go about without the least inconvenience. I proposed to remove the pessary and stem at the end of the term specified, by which time the uterus had grown straight; but as a precaution against any relapse, I proposed the insertion into the vagina of a single ring of gutta-percha, made by bending a rod of that material a quarter of an inch in diameter into a circle of the same diameter as that of the boxwood pessary just removed from the vagina. When such a ring is introduced into the vagina, and the woman stands up, it assumes the same position as a flat pessary does, namely, a very oblique one. If the finger be passed into the vagina of a woman in the erect position whilst she is wearing a flat round pessary, the instrument will not be found lying horizontally, but very much sloped; its anterior margin will be felt low down behind the pubes, while the posterior rises high in the back of the vagina behind the cervix uteri. The ring, when introduced, assumes the same position, and while the posterior part of its periphery rises up behind the cervix, and offers resistance to the fundus if disposed to fall back, the cervix is permitted to pass through the wide ring, and descend to its proper position in the vagina. The uterus, previously straightened by the uterine stem, is thus kept in its natural form by this simple means. The ring may be removed at the end of six weeks or may remain longer, for it does not interfere with any of the functions of the vagina.

\* Read in the Midwifery Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

Since that paper was written in 1862, I have treated all cases of retroflexion of the uterus on the principles just mentioned and by the means which I have described, and the result has been in almost every case a radical cure. As an example, I will give some particulars of the last case of the kind that was under my care.

A lady, twenty-four years of age, married four years, the mother of one child, born twelve months after marriage, began to complain two years ago of pain in the back and in the hypogastrium, with a sensation of bearing down. These symptoms gradually increased in severity until at last she was scarcely able to walk, and defæcation was performed with great difficulty. On examination *per vaginam*, I found a complete retroflexion of the uterus with a very acute angle between the body and the cervix. The curve was so sharp that I was obliged to bend the uterine sound much beyond the usual curve before I could make it enter the body of the organ. By turning the sound the uterus was straightened, and the prominent tumour behind was completely removed. On withdrawing the sound, the fundus immediately came down, and the distortion was resumed. I told the lady the nature of her case, and that it would be necessary to introduce some instruments which she would wear for some time. Accordingly, on the 12th of last May, I proceeded to pass the stem pessary, but I found great difficulty in doing so, for the uterus was so confirmed in its bent condition that, the instant the sound was removed, and before the stem could be made to enter, the fundus flew back to its unnatural position. I succeeded at last by passing the stem alongside the sound while it remained in the uterus, and I then withdrew the sound, leaving the stem, which kept the uterus quite straight. The flat boxwood pessary was then inserted, and the lady was directed to remain in bed that day.

On coming the next day to see her, I found her so free from any inconvenience that she was unconscious of the presence of the instruments, and asked when I was going to introduce them. The instruments were perfectly in their place, and she was allowed to get up and go into the drawing-room, but not to go out. On the third day I again examined and found everything in its place, and she said she felt better than she had done for many months. The menstrual period was expected in ten days, and I cautioned her that she would probably find it more profuse than usual. This was the case; and it lasted a week and then went off. She used the syringe daily with a weak solution of sulphate of zinc and alum, and went out walking and driving with perfect freedom. On the first of July, the instruments having been then seven weeks *in situ*, I removed them, and found the uterus quite straight. I then passed the plain ring into the vagina, and she left town for the country the following day, and I have not heard of her since.

Subsequently to the publication of my proposal to treat retroflexion after this manner, Dr. Graily Hewitt, in his admirable work on the *Diseases of Women*, suggested a somewhat similar proceeding, using a stem of ivory, and supporting it with a ball of India-rubber, inflated after being passed into the vagina. This, no doubt, is a very good means, but I do not think it as simple as that which I have described; for Dr. Graily Hewitt says, "It is not advisable for the instrument to be worn longer than two or three days at a time, and after each removal the vaginal douche should be freely used." Now, this entails an amount of trouble and attention to the case which is not required in my plan, for, when once the proper sized flat pessary has been introduced, no further attention to the case is required until the time comes for taking all out, and then, the ring being placed *in situ*, the patient may go where she likes for six or eight weeks or longer.

## INJURY TO THE AXILLARY ARTERY, CAUSING GANGRENE OF THE UPPER EXTREMITY.\*

By WILLIAM R. E. SMART, M.D., C.B., Inspector-General R.N.

INJURY of the axillary artery by forcible extension, without puncture or laceration of the integuments, is not a common accident. Three cases of it in gunnery practice have come to my knowledge; and, as their record may prove useful, I present them at this large professional assembly at one of the chief naval and military stations. They all occurred from explosions in the act of ramming home, by which the rammer was expelled, driving backwards the arm employed in loading.

CASE 1.—J. F., aged 23, was injured in a battery before Sebastopol on April 9th, 1855. The thumb and forefinger of the left hand were

lacerated; the acromial end of the clavicle was luxated, its ligaments being torn; and the parts about the shoulder very soon became tumid. I first saw him on the 10th, within thirty hours of the accident. The thumb was in a state of sphacelus; the hand gangrenous. The forearm was insensible halfway to the elbow, but retained warmth downwards to that point; while emphysematous crackling was traceable up to the joint. The shoulder and parts to the mesial line above and below the clavicle were much swollen, with lividity along the anterior border of the axilla. No pulse could be discerned in the brachial or radial arteries. The outer end of the clavicle was raised up, but could be easily replaced by pushing it backwards, when it seemed to float up again at once. A tremor of uncertain pulsation was detected in the tumour; but the transmitted sounds were those of the first stage of pneumonia or a large crepitation, and not of a blood-current. Respirations 40; pulse 108; skin warm; tongue not foul; no sleep.

Third day.—Gangrene was extending up the inner side of the forearm; its veins were turgid. There was a large bulla above the wrist. Towards evening, there were anxiety of face and hard pulse. A whirring sound was thought to be detected deeply in the tumour. The sputa were bloody in dotted points, and non-vascular. Respirations 48, laboured; pulse 108, compressible.

Fourth day.—He was delirious in the night, but calm again in the morning. Emphysema extended to the inner side of the arm.

Fifth day.—The gangrene was not extending; there was no mark of its limit. He had increased cough and pneumatic signs.

Sixth day.—There were appearances of demarcation above the wrist. There was less anxiety. Pulse 98. He had evening exacerbation of fever and fits of cough, with blood-clots in tenacious sputa.

Seventh day.—Vesication and a sphacelated spot appeared above the inner condyle. Respirations 43; pulse 104; tongue dry at point.

Ninth day.—The forearm was in a state of complete sphacelation, and on that account it was taken away at the elbow. A small vessel required ligation at the posterior part. No pain was felt. Incisions were made into the emphysematous parts above the elbow. During the last few days, the axillary tumour had decreased somewhat, through decline of the superficial swelling.

Tenth day.—Pus appeared on the cut surfaces.

Eleventh day.—There were vesications in the axilla. Incisions made into it bled freely.

Twelfth day.—He was hectic and drowsy. A livid blush extended over the front of the chest. Deep incisions at the anterior border of the axilla gave exit to serous fluid mixed with pus and broken coagula, not of offensive odour. The swelling of the parts and the pain were diminished by this.

Thirteenth day.—There was some blood, but little pus, in the dressings. The gangrene was not extending. He had a hectic flush. Pulse very rapid; respirations hurried.

Fourteenth day.—There were vesications at the back of the shoulder, slight supuration of the incisions, and granulations in the axilla. In the evening, the secretions were checked.

Fifteenth day.—Gangrene was extending. The shoulder and side of the chest were emphysematous. The pain suddenly ceased, and he died at 11 A.M.

Necropsy, six hours after death.—There was rapid decomposition of the corpse. Blood was extravasated in the adipose tissue and muscles of the pectoral region. The ribs and clavicle were sound. The acromial ligaments were ruptured. The shoulder-joint was unaffected. A large cavity of the size of a clenched fist, filled with broken-up coagulum, extended from the axilla inwards under the pectoral muscles and the clavicle; its walls were jagged and sloughy. The artery was pervious to an inch and a half below the clavicle; it was of small calibre, and filled with a well formed black clot. The vein was pervious for two inches, and then was contracted to a point; its walls were softened, and its lining coat blood-stained. Both vessels were lost in the sloughy mass that formed the posterior wall of the cavity. The brachial artery lay flattened and uncontracted, and its inner coat was blood-stained. The brachial vessels and nerves were matted together by infiltrated areolar tissue. There was no pleural effusion. The left lung was adherent at the upper lobe, which was condensed and heavy, and contained air with localised or lobular extravasations of blood, and a few gritty particles like obsolete tubercles. The lower lobe was natural.

REMARKS.—It was evident from the beginning that the axillary artery had been injured. When the patient came under my charge, gangrene had begun, and there was so much infiltration at the base of the neck as to annul the proposal to tie the subclavian at its inner third, amputate at the shoulder-joint, and clear out the cavity. The alternative was to

\* Read before the Surgical Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

wait events; and the hope was entertained of a line of demarcation being formed through the force of the collateral circulation in the upper arm, which would give the sign for amputating with some chance of success. The vitality that set up suppurative action in the incisions in the upper arm, the apparent check to the extension of gangrene, the complete occlusion of the axillary artery, and the conversion of an aneurismal sac so near the centre of the circulation into the condition of an extravascular effusion ending in an abscess, and, finally, the sudden failure of vitality and the rapid extension of what may be termed hospital gangrene, in contradistinction to the precursory gangrene through want of arterial blood, are features of the case that came out in strong relief. The course of events and the necropsy impressed me that in these accidents the traumatic condition of the artery is similar to that produced when the limb is torn off by machinery without hæmorrhage, a vessel like the axillary not requiring ligature in such case. The inner coat is the first to yield; it is rippled up, and the torn subserous filaments serve to entangle fibrine, that fills up and occludes the artery, after which primary hæmorrhage is not likely to occur. The cavity containing the extravasated blood being then converted into an abscess, as in this case, or the serous portion being absorbed, and its fibrine and corpuscles degenerating into mere connective tissue, there would be a spontaneous cure, as far as the injury to the vessel is concerned. The sudden cutting off the supply of blood without precursory adaptation of the collateral circulation, however, tends at once to loss of vitality of the limb; and, if there be laceration of the extreme points, sphacelus sets in with rapidity, as in this instance. When this case fell under my care, I knew nothing of this form of injury; but its result taught me that it would be the duty of a surgeon not to wait for line of demarcation to form, but to amputate near to the trunk as soon as any sign of gangrene presents; and I inculcated these ideas to others. Since then, two cases have become known to me, which recovered after amputation, without interference at the seat of injury to the axillary artery.

CASE II.—At Corfu, on our Queen's birthday, in 1856, an Austrian schooner of war, in firing a royal salute, had two men blown overboard in loading a cannon. I saw these men as soon as they were picked up and laid on the deck; one had lost both hands, and the other was whole, but greatly "shocked." His surgeon thought little of his case, as one simply requiring a stimulant. Warned by the case related I felt for the pulse, and found it absent; then, on examining the shoulder, I felt an increasing soft tremor, and diagnosed the case. Both men were sent ashore; and, after gangrene had extended to the forearm, amputation was performed about the ninth day, in the upper arm, by Surgeon Webb, of the Military hospital, the aneurismal tumour being treated by ice-bags. When the stump had healed, the patient was sent home.

CASE III.—The next case was made known to me, at the time of its occurrence, by an officer who was familiar with my advice, "to amputate early and leave the axillary artery untouched," as he knew I would gladly receive confirmation of it.

In the year 1868, a seaman was "blown overboard," from an Italian frigate at Spithead. He was sent to Haslar Hospital, where gangrene of the hand supervened; there were absence of radial pulse, early loss of heat and sensation, with great extravasation. The limb was amputated in the upper arm forty-eight hours after the accident, by Deputy Inspector-General Mason. There was no bleeding, and only one small twig required a ligature. The patient recovered without any interference with the vessel at the seat of rupture.

I consider this last case to have been like the first, in its most essential features; and I think that, had I been equally prompt to amputate, the unfortunate man's life might have been spared. I am not prepared to say to what extent, if any, the hand was injured in this last case, but in the second case there was no injury of it.

I am inclined to believe that, where the hand is blown away, the chances of injury at the shoulder are much less; and the only reason I can offer for this is that, when the explosive force is great enough to carry away the parts next to the muzzle of the gun, the leverage is at once destroyed, by which the whole arm would be thrown back with the disruptive force necessary to stretch and lacerate the soft parts which connect it to the trunk. In my early career I knew several cases in which a hand had been blown off in loading a gun, in which primary amputations were performed; but I never heard of suspicion of injury to the axillary artery in such cases. The same reasons will apply when both hands are lost, as in the gunmate No. 2, who lost them without system-shock to prevent amputation of both within three hours of the accident. In case No. 1 the injury to the hand was simply so much as can be caused by a rope or a rammer-staff running rapidly in contact with soft parts, but the arm was thrown back with immense force, as the force of the explosion was not expended on the hand.

## LOOSE CARTILAGES IN THE KNEE-JOINT AND THEIR REMOVAL BY SUBCUTANEOUS INCISION.\*

By WILLIAM J. SQUARE, F.R.C.S.,

Surgeon to the South Devon and East Cornwall Hospital, Plymouth.

ABOUT ten years ago, I published nine cases of loose cartilage of the knee-joint, and their cure by the operation of subcutaneous incision. Since that time, my experience has been enriched by the addition of fifteen like cases, treated in the same manner. All these twenty-four cases have been operated upon without selection, just as they presented themselves; all have been cured without drawback or accident.

The present occasion appears to be a most fitting one to set forth and advocate the safety and claims of this operation. By reference to our current surgical literature, I find that the old operation of direct incision still has its advocates; and that its results are now, as heretofore, uncertain and dangerous.

My attention was first directed to the consideration of the subcutaneous operation from witnessing the bad results of two operations for the removal of loose cartilages from the knee-joint. One man, now alive in this town, submitted to amputation of the thigh to save his life; the other, a woman, less fortunate, died. In 1860, Sir William Ferguson removed a loose cartilage from the knee-joint by valvular incision. The patient was attacked with severe synovitis, ran great danger of his life, and recovered with a stiff joint. About five years ago, the nephew of a distinguished physician of this county consulted Mr. Whipple for stiffness of his knee-joint, the result of the removal of a loose cartilage by the direct method, by a deservedly eminent metropolitan surgeon. Mr. Whipple asked my opinion on the case. The patient told us that his life was in great jeopardy for many days after the operation, in consequence of inflammation, with fever and delirium. I could multiply examples, but these will suffice.

In his address delivered before the British Medical Association in 1865, Mr. Syme says: "The cartilaginous bodies which are so troublesome in the knee-joint, were formerly regarded as an unsatisfactory subject of treatment, on account of the inflammation which was apt to attend their excision; but the subcutaneous operation suggested by myself in 1841, and afterwards improved by Mr. Square of Plymouth, has afforded a means of remedy both safe and easy."

The operation which I perform was worked out by myself, as I could never find any account of the method recommended by M. Goyrand or Mr. Syme. It is as follows.

I first endeavour to conduct the loose cartilage to the inner and lower part of the joint, just above the articular edge of the tibia; it is then entrusted to an assistant, who firmly fixes it in that position. A strong tenotomy knife, at least two inches long, is thrust through the skin at such a distance from the cartilage that it can be readily cut upon. The capsule of the joint is freely and decidedly incised upon the cartilage through its whole length. The knife, being disengaged from the cartilage, is directed so as to open up the cellular tissue over a convenient part of the fascia of the limb. The cartilage is now pressed and lifted out of the joint into the cellular bed prepared for it, and slid along the cellular tissue for about three inches. It is fixed *in situ* with a firm pad and adhesive plaster; the foot and leg are bandaged up to the edge of the displaced cartilage, the limb attached to a straight splint, and placed at about an angle of forty-five degrees. If no inflammatory symptoms ensue, the cartilage is excised about seven days after the operation.

CASE I.—James Ellis, aged 33, farm servant, was admitted into the South Devon and East Cornwall Hospital on December 3rd, 1856. He had been lame eighteen years, and distressingly so during the last twelve months. Two movable bodies were easily felt in the right knee-joint; they had been there fourteen years. They glided from one part of the joint to another with extreme mobility, and caused great pain and sudden lameness. The joint was often distended with synovia. He stated that these cartilages had distinctly increased in size.

Operation, December 8th.—I fixed the cartilages firmly at the lower and outer part of the joint, and entrusted them to an assistant. Two subcutaneous separations of the cellular tissue were then made with a tenotomy knife two inches in length, at two separate punctures. From the lowest puncture, the knife was directed upon the largest cartilage, and the synovial membrane freely incised upon it. The cartilages, being slid into the bed prepared for their reception, were fixed at its extremity with a pad of lint, adhesive plaster, and bandage. A straight

\* Read before the Surgical Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

splint was applied along the back of the limb, which was raised to an angle of forty-five degrees, and cold-water dressing applied.

December 22nd.—He had had no pain, effusion, or other signs of inflammatory action. The cartilages were therefore excised. They were of a yellow, waxy, polished appearance. One side of the larger one was smooth; the other had a worm-eaten look. They were both covered with a fine membrane. They were composed of bone and cartilage, with a predominance of the former.

December 30th.—He was discharged cured. A very slight stiffness of the joint remained.

CASE II.—Robert Windsor, aged 27, farm servant, of healthy constitution, had a loose cartilage of the size of a walnut, readily felt in the left knee-joint. It had existed a year, and had given rise to the ordinary symptoms.

Operation, April 28th, 1858.—The cartilage was firmly fixed by Mr. Fox at the upper and outer part of the joint. I punctured the skin with the tenotomy knife, two inches above the cartilage; by a semicircular sweep made a bed for it in the cellular tissue; and then cut upon it at right angles, freely dividing the joint-capsule. The body now escaped from Mr. Fox's grasp. I, however, brought it again to the wound in the synovial membrane, and squeezed it into the subcutaneous tract. The patient was treated as detailed in Case I. On May 4th, no pain or inconvenience had arisen. The cartilage was excised. On May 6th, he was discharged; he walked well.

CASE III.—Edward Mitchell, aged 30, of good constitution, came under my care on May 13th, 1858. In his right knee-joint were three foreign bodies, the smallest of the size of a large pea. They glided with amazing swiftness into various parts of the joint, and could only be fixed just in front of the internal lateral ligament. There was no synovial thickening, nor effusion. Two years previously, he discovered a loose body in the joint, but he had already been lame for some months. Two months before I saw him, he discovered a second, and, a fortnight ago, a third foreign body. His conviction was, that the first discovered cartilage was larger than any now in the joint; whence the inference that the two last discovered were produced by the disintegration of the first.

Operation, May 15th.—The cartilages were fixed at the lower and outer part of the joint. The puncture and subcutaneous incision were made as in Case II. I endeavoured to push the cartilages out of the joint, but the pressure caused the one to recede into its cavity. With great trouble, the patient presented one of the cartilages at the synovial incision, and I pressed it out of the joint into its bed. Ten minutes of continuous manoeuvring were consumed in getting a second cartilage into the subcutaneous tract, but the third could not be found. The cartilages were retained *in situ*, and the patient treated as before described.

On May 21st, the cartilages were excised; and, on the 28th, he returned home, the motion of the joint being perfect, but rather weak.

CASE IV.—John Ellacott, aged 40, a healthy farm servant, was admitted into the South Devon and East Cornwall Hospital on September 8th, 1858, under Mr. Whipple. A loose cartilage of the size of a horsebean was readily felt in the right knee-joint. He had the ordinary symptoms of the malady. He discovered the cartilage a year previously. It had not increased in size. He never had an accident. On September 10th, the ordinary subcutaneous operation was performed. On the 14th, the cartilage was excised. No inflammatory symptoms occurred, and he was discharged cured.

CASE V.—Medland, a miner, of good constitution, was operated upon by Mr. Whipple in 1859. The patient had recognised the presence of a large cartilage for about three years. His symptoms were very severe, and the pain at times was excessive. The operation was performed in the usual manner, and the cartilage was excised on the eighth day. No inflammation followed. He walked four miles the day after the excision of the cartilage, six the next day, and four days afterwards resumed his labour.

CASE VI.—Francis Warren, aged 20, farm-labourer, of robust constitution, was, in March 1859, suddenly attacked with severe pain in the right knee joint, with much swelling. Under surgical care, he was relieved, but never entirely lost the pain in the joint. In October of that year, he first discovered the existence of a loose cartilage. It was of medium size, and very difficult to fix.

Operation, January 25th, 1860.—I performed the operation of subcutaneous section, with the intent of embedding the cartilage in the cellular tissue of the thigh, but, from its excessive mobility, failed to do so. The patient was treated as if the operation had succeeded. No inflammation followed. On February 8th, the operation was repeated, with this difference, that the subcutaneous separation was made over the inner surface of the tibia. I now succeeded in placing the cartilage in the space prepared for it. He was treated in all respects as before described. On February 15th, no inflammatory action had been excited; and, on the 20th, he was discharged cured.

CASE VII.—William Davey, aged 24, a healthy farm-servant, had had his right knee weak for years. He discovered a loose cartilage in it nine weeks before he came under treatment. It was flat, and about the size of an almond. On May 11th, 1860, by subcutaneous incision, the cartilage was embedded in the cellular tissue on the inside of the head of the tibia. By pad, plaster, and straight-back splint, it was retained *in situ*. On May 18th, the cartilage was excised. On the 25th May, he was discharged cured, walking well.

CASE VIII.—Wm. Davey was readmitted February 5th, 1861. For some weeks he had felt another cartilage in the same knee-joint. On February 8th, I attempted the usual subcutaneous operation, but failed to dislodge the cartilage. The treatment was as before; no bad result followed. On February 22nd, the operation was repeated, and again unsuccessfully. He was treated as before, and with like immunity from inflammatory action.

On April 24th, Wm. Davey was again admitted into the Hospital. On the 26th, I again performed the same operation, but without success. His treatment was as before. On May 20th, he had had no pain or bad symptom. He was discharged for readmission.

CASE IX.—William Davey was readmitted March 26th, 1862. He had now two loose cartilages in the right knee-joint. He discovered the second and larger one about a fortnight since. On March 28th, the smaller cartilage being well fixed at the inner and lowest part of the joint, I lodged it in the cellular tissue over the inner side of the head of the tibia, and then without difficulty pressed the larger one into the same tract. On April 4th, the cartilages were excised; and, on the 11th, he was discharged cured.

CASE X.—Joseph Badcock, aged 39, gamekeeper, of healthy constitution, was admitted into the Hospital, under the care of Mr. Whipple, on April 18th, 1861. He had felt the cartilage (which was now very large) for fourteen years. He had the ordinary symptoms, and was very lame. There was much synovial effusion and thickening.

On April 19th, Mr. Whipple operated successfully. The patient was treated in the ordinary way. On May 6th, the cartilage was excised. It was of very irregular outline and very nodulated. On the 16th, he was discharged; he had had no pain. Some synovial effusion and lameness remained. On June 13th, he was seen by Mr. Whipple; he was much better, and walked well.

CASE XI.—John Hart, aged 62, labourer, robust and healthy, had a loose cartilage: it was distinctly felt in the left knee-joint, which contained some synovia. Eighteen years previously, he had sudden inflammation of this joint, and on its subsidence felt the cartilage, which was of the size of a horsebean. On September 9th, 1865, I performed the subcutaneous operation, the cartilage being fixed at the inner and lowest part of the joint by Mr. Fox. The limb was dressed and placed as usual. No symptoms occurred. On September 29th, the cartilage was excised. On the 30th, there was slight erysipelas round the wound. On October 3rd, the skin around the wound was still inflamed; the joint was intact. On October 10th, slight suppuration occurred at the cutaneous orifice; and on the 26th the wound was still a little open. On November 5th, he was discharged cured.

CASE XII.—Robert Mortimer, aged 47, farm-labourer, of healthy aspect, was admitted August 24th, 1866. The left knee-joint contained a loose cartilage of the size of a horsebean. It could only be fixed at the upper and outer part of the joint. He had felt it four months. The symptoms had been very severe. On one occasion he fell suddenly, and could not rise without help. On August 26th, I performed subcutaneous incision with success. On August 31st, not the least pain or swelling had taken place. I excised the cartilage, which was globular, smooth, and white. On September 5th, he was discharged cured.

CASE XIII.—George Symonds, aged 37, gardener, had suffered from loose cartilage four years, often so seriously as to be confined to his bed for days together. On February 25th, 1868, a loose cartilage of the size of a horsebean was distinctly felt in the left knee-joint. On February 28th, I performed the subcutaneous operation. I pushed the cartilage out of the joint; but, being pressed very firmly, it slid behind the hamstring tendons, and could never be found again. On the 29th, he had passed a restless night, and was feverish; pulse 100. There was no pain of the joint. On March 1st, there were some synovial effusion, and tenderness of the joint on pressure. On the 4th, the effusion was absorbed. On the 14th, there was no trace of the cartilage. He was not lame, but there was slight stiffness of the joint. On the 18th, he was discharged cured.

CASE XIV.—Robert Doidge, aged 55, farm-labourer, was admitted May 1st, 1868. A very large loose cartilage was felt in the left knee-joint. It had been a tenant of the joint for the last thirty years, and a very troublesome one too. Mr. Whipple removed it by subcutaneous incision (with great difficulty) in the usual way. After excision, it was

found to weigh 110 grains, and to measure one inch and one-eighth in the long, and half an inch in the transverse diameter. On May 22nd, he was discharged cured, never having had a bad symptom.

CASE XV.—Thomas Hennessy, aged 17, bricklayer's labourer, came under care on August 12th, 1868. Three weeks previously he first felt what he called a bone in his left knee-joint. It gave him great pain. He sometimes fell, and could not rise or walk until the cartilage was dislodged from its position. On August 21st, the cartilage being fixed at the inner and lowest part of the joint, it was removed from the joint, and embedded in the cellular tissue in the ordinary manner. The treatment was as usual. On September 9th, he had had no bad symptom. The cartilage was excised; it was of the size and shape of a hazel-nut. On September 14th, there had been slight suppuration in the cellular tract since the removal of the cartilage; otherwise he was quite well. On the 16th, he was discharged cured.

CASE XVI.—Mary Hayman, aged 22, servant, was operated upon by subcutaneous incision by Mr. Whipple on December 2nd, 1868, and discharged cured on December 22nd. There is no history of this case; but it is evident that the result was perfect, not only from the statement of her cure in the hospital admission-book, but also from the fact that she was only twenty days under treatment.

CASE XVII.—F. Johns, aged 20, had a loose cartilage in the knee-joint, and was operated upon by Mr. Fox by subcutaneous incision in the South Devon and East Cornwall Hospital. I can find no record of this case; but the cure was complete without accident, and I am enabled to show you the cartilage with an inscription referring to the case.

CASE XVIII.—John Hocking, aged 51, miner, came under treatment May 25th, 1870. A loose cartilage was very evident in the right knee-joint. Fourteen years ago, he received a severe blow on his knee, and ever since had felt the foreign body in the joint. It gave him little annoyance until a fortnight ago, when the joint became distended with synovia; and ever since that time he had frequently fallen while walking, from the sudden movement of the cartilage.

Operation, May 25th.—The cartilage was with great difficulty fixed on the outer side of the joint. I was obliged to incise the capsule of the joint most freely; and by patient long continued manipulation I lifted the cartilage from the joint into its cellular bed. I fixed it with a firm pad, adhesive plaster, and bandage, in the usual way; and placed the limb on a straight splint, at an angle of forty-five degrees. On June 8th, he had no pain or swelling. The cartilage was excised. On July 1st, he was discharged cured. Some delay in his cure arose from a slight suppuration which occurred in the wound from which the cartilage was removed.

CASE XIX.—G. Gorlett, aged 38, ironfounder, was operated on September 10th, 1869, when the subcutaneous operation for loose cartilage in the knee-joint was performed by Mr. Whipple at the hospital. On September 29th, he was discharged cured.

CASE XX.—Wm. Teale, aged 52, sailor, was admitted into the South Devon and East Cornwall Hospital February 4th, 1870, with loose cartilage in the right knee-joint, under the care of Mr. C. Whipple, who operated upon him by subcutaneous incision on February 6th. He was discharged cured on March 23rd. He had no bad symptom during the treatment.

CASE XXI.—Wm. Bennett, farm-labourer, Landulph, was operated upon by subcutaneous incision by Mr. Kempthorne. He was treated as before described, and was cured without the occurrence of any bad symptom.

CASES XXII, XXIII, and XXIV, were operated upon by Mr. W. Swain, of the Albert Hospital. They were all operated upon by subcutaneous incision, were treated on the plan before indicated, and all recovered without a bad symptom.

Since writing the above paper, I find a case reported in our JOURNAL for July 29th, 1871, by Mr. Alford, of the Taunton and Somerset Hospital. There were two loose cartilages in the right knee-joint. On May 1st, they were lodged in the cellular tissue of the thigh. On the 20th, they were excised; and on June 20th the patient left the hospital cured.

I have now given you a short report of twenty-four consecutive and unselected cases, cured, without anxiety or accident, by subcutaneous incision. Surely immense responsibility must henceforth attach to any one who ventures to incur the risks of direct or valvular incision. I most sincerely hope that these splendid results may carry conviction to all your minds.

When Mr. Syme had for the first time performed the operation which I advocate, he was so satisfied with it, that he said to his class, "When the safety and facility of this procedure are contrasted with the danger of excision and the irksome confinement to bed of several weeks' duration, which is requisite for accomplishing the process of fix-

ture, I think that there can be no doubt that the profession is greatly indebted to Mr. Square for perfecting the subcutaneous operation and rendering it available for all cases of the disease."

There are several varieties of loose cartilages. I am acquainted with five; and probably there are more. One variety originates in masses of lymph which have been effused by the inflammatory process. They may be termed fibrinous exudations. The second is a mere precipitate from a morbid synovial secretion. Rokitsky says that these loose bodies are often laminated. The third variety is described by Dr. Robert Adams, who calls them "addimentary bones". They are formed around the cavities of joints, or upon their articulations, in the course of chronic rheumatic arthritis. They often separate from their attachments, and become loose in the cavities of joints.

These three varieties have little surgical significance; but the two others are in this respect of more importance. The fourth variety is produced by the abnormal or morbid growth of the fine fringes of the synovial membrane. Kölliker states that these processes increase in size, solidify, and become detached from the vascular folds. These loose cartilages are composed principally of hyaline cartilage, and present calcified spots, generally about their centre. The fifth variety is of all the most important to surgeons, as it furnishes the majority of cases for operation. I here show you specimens from patients whose cases are recorded in this paper. Their surface on one side is smooth and shining, having a yellowish waxy aspect. On the other side, they often have a bony appearance and structure. The yellowish waxy portions consist of true articular cartilage, and the opposite side of true bone, as demonstrated by the microscope.

In the short paper which I published in 1861, I said "that a large proportion of these cases are the result of local injury—that, by accidental violence, small or large portions of the articular structures are detached." In the fourth volume of the *St. Bartholomew's Hospital Reports* is an excellent paper by Mr. Marsh, referring to this variety of loose cartilage. He says: "The forms of disease to which I wish to draw especial attention here is one that has been referred to by several surgical writers, although its occurrence has never, I think, been generally acknowledged. It is that which results from the breaking off or shedding into the cavity of a joint of a portion of the proper articular cartilages, together with a layer, more or less substantial, of the subjacent bone."

In the sixth volume of the *St. Bartholomew's Hospital Reports*, Mr. Paget has a paper on the Production of Loose Cartilages in Joints, in which he expresses his opinion, based upon facts observed by himself, that this group of loose cartilages has its origin in violence resulting in what he calls quiet necrosis. He says that these bodies are sequestra exfoliated after necrosis of injured portions of cartilage, and exfoliated without acute inflammation. In a note, Mr. Paget remarks that the late Mr. Teale published a like explanation of the occurrence of this form of loose cartilage in the thirty-ninth volume of the *Medico-Chirurgical Transactions*.

## DESCRIPTION OF A NEW STRICTURE-DILATOR.\*

By BERKELEY HILL, F.R.C.S.,

Surgeon to University College and the Lock Hospitals.

THE dilator that I venture to show you operates on the principle of Perrè's, Holt's, and Richardson's. The two halves of a split sound, which in juxtaposition equal the calibre of a No. 2 or No. 3 catheter, can be separated by thrusting between them a segment of a cone fixed to a slender stem. This cone or olive separates the blades till they occupy a space equal to No. 12, this to a No. 14, and this to No. 16, of Weiss's catheter-scale.

In using the instrument, I first explore the urethra with an olive-headed graduated bougie, to ascertain the position of the stricture. I then introduce the dilator with the blades approximated until this portion, which is bluntly knife-edged, lies in the stricture. The cone is next passed down between the blades, and bursts the stricture with very little force. The largest cone produces slight laceration of the meatus, which is of no moment, or that may be previously incised; but it has no injurious effect upon the elastic healthy part of the urethra.

The advantages which I anticipate will be found to belong to this dilator are, first, simplicity and cheapness of construction. The numerous parts of Holt's instrument raise the cost to nearly three guineas; while I am informed by Mr. Coxeter, who has very ingeniously carried out my ideas, that this can be made for a guinea and a half, if not for less.

\* Read in the Surgical Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

Again, the central guide of Holt's instrument is not needed in mine: hence this split sound can be passed through narrower strictures. It is true that, by doing away with the central guide, we lose Smyly's addition of a catheter to the dilator, whereby an unskilful operator may be satisfied that he has kept the true path to the bladder, and not diverged into a false passage. But this advantage is not practically a great one in actual use. The fine tube often gets blocked by mucus; and the operator seldom needs to see the urine flow to be assured he has passed through, and not by the side of, a stricture.

The third and chief advantage is this—diminution of resistance. The force needed for Holt's dilator is sometimes very great; indeed, I have seen his instrument break in the most skilful hands from this cause. Much of the power is required to overcome the continuous friction of the tube, both inside along the guide and outside on each half of the split sound. It is true that the necessity for excessive force has been overcome by screwing down the dilating tube; but what seems to me a very important point in Holt's plan of treatment is thus lost—namely, rapidity. The slowness of a screw fails to completely break through all the indurated tissue: part is only stretched, and soon contracts again. In the dilator before you, the friction-surface is reduced to these two dovetail grooves, which together do not measure more than half an inch. The rapid application of the wedge to the stricture is obtained by a force so small, that one hand has hitherto sufficed to overcome the resistance.

It is not my intention to occupy your time in discussing the relative merits of treating stricture by suddenly breaking through the patch of induration which causes it, and of slowly dilating by repeated passage of bougies. This question has been recently debated by the profession. Mr. Holt's plan is proved and acknowledged to be a safe, easy, and speedy mode of treatment. There are, however, two points which have not yet, so far as I am aware, been much insisted upon. Nevertheless, I am supported in my opinion by that of my teacher and colleague Sir Henry Thompson. Rupturing the tissue is not applicable to penile strictures or those anterior to the bulb. Here incision is preferable, because the new matter abundantly produced to repair the rent often blocks up the spongy tissue so much as to prevent or impede erection beyond the point ruptured. A clean internal incision does not cause the same amount of plastic formation, and hence subsequent erection is not interfered with after this mode of division.

The second point is this: No. 12 is rarely large enough to split all the fibres of a stricture; some are only stretched, and contraction returns as soon as after gradual dilatation. Hence I have carried the size of the cone to No. 16 for urethras where the calibre naturally approaches No. 10 and No. 12.

The instrument is only just out of the maker's hands; hence my experience is limited to four cases, in all of which the urethra has been fully dilated; the patients have had no bad symptoms whatever, and they have been detained in bed only a few hours.

CASE I.—M., aged 28, was admitted to University College Hospital July 15th, 1871. Difficulty in passing urine had been noticed three months. A No. 4 olive bougie stopped at six inches. The dilator with No. 14 cone was passed under chloroform. The stricture yielded at once. There was pretty free hemorrhage. No instrument was introduced after the dilator was withdrawn. On July 16th, urine had passed very well the previous night, and the patient slept all night without any opiate. On July 18th, I passed a No. 12 probe-ended catheter, and drew off the urine. He attends twice weekly to have a bougie passed, until he can pass one himself.

CASE II.—J., aged 31, a horsekeeper, was admitted to University College Hospital July 20th, 1871. Difficulty in passing his urine had been felt for twelve years, and the patient had several times been relieved of retention at this hospital. At 4½ inches, a stricture was found, through which, after some difficulty, a filiform bougie, about No. 4 in size, was passed and tied in. For micturition, the patient was twice compelled to withdraw the bougie, but replaced it himself. On the 21st, a ¾ catheter was passed and tied in. On the 24th, the dilator was passed with the No. 16 cone. Very little hemorrhage took place, and by a No. 13 catheter the urine was drawn off. On the 26th, the No. 13 catheter was easily introduced, and the patient is now learning to pass his own instrument regularly.

CASE III.—August 27th. A gentleman since 1867 had kept his stricture dilated by the occasional passage of No. 10 and 11 bougies. Notwithstanding this, an abscess ending in perineal fistula formed in 1870, which apparently healed, to break open again with abscess three times, though the patient had been careful after each abscess to draw off his urine regularly through a catheter. This being his third attack, the patient begged me to do something to prevent its recurrence; and on August 2nd, Dr. Squarey giving chloroform, I burst the stricture by the No. 16 cone, and passed afterwards a 16 pewter sound to the blad-

der. No bad symptom occurred. There was very little pain in passing urine the first time; none after that. No. 13 passed easily on August 4th and 6th.

## ON THE PHYSICAL GEOGRAPHY AND CLIMATE OF SPAIN, AND OF ITS HEALTH-RESORTS.\*

By JAMES HENRY BENNET, M.D.,  
Late Obstetric Physician to the Royal Free Hospital, London.

IN order to understand the climate of Spain, it is absolutely necessary to be acquainted with its physical geography. The peninsula of Spain is constituted by a plateau or table-land, upraised some two thousand or more feet above the sea, and intersected from east to west by a series of mountain ranges all but parallel to the Pyrenees. The principal of these mountain ranges are the Sierra Guadarrama, the Sierra Toledo, the Sierra Morena, and the Sierra Nevada. The table-lands between these ranges were formerly the beds of seas, of estuaries, and of fresh-water lakes, and are now traversed by rivers, in a direction parallel to the mountain ridges, which empty themselves into the Atlantic or Mediterranean. All the larger rivers, with the exception of the Ebro, direct their course to the Atlantic.

The main mountain chains of Spain are of primary formation, and constitute the basis of its geology. They emerged before the secondary strata which surround them, and are formed of granite, gneiss, crystalline schists, etc. Secondary rocks, represented by the trias triple, and also by the jurassic and cretaceous formations, occupy a vast area in the eastern and southern regions of Spain. In the table-lands, plains, and river-valleys, are found tertiary, old and recent, nummulitic rocks, as also miocene and pliocene formations. Fresh-water miocene fossils are found at an elevation of two thousand five hundred feet, which shows how greatly the peninsula of Spain must have been raised in comparatively recent geological times.

Below this central table-land of Spain is the coast, sometimes a mere ledge or undercliff, like the Undercliff in the Isle of Wight, or the Genoeese Riviera, but often presenting small alluvial plains of greater or less width, watered by rivers that descend from the mountains, and from the elevated plains of the interior.

Thus, Spain may be compared familiarly to a square dining-room table, with a narrow ledge of coast on the floor. Of course the climate of the upraised mountainous table-land, and that of the subjacent coast, must be, and are, very different. Although Spain lies far south, between the thirtieth and the forty-fourth degrees of latitude, an elevation of two or three thousand feet does not protect its interior from intense scorching heat in summer. The city of Madrid, which is two thousand seven hundred feet above the sea, in midsummer is one of the hottest and most burnt up cities in southern Europe. But this altitude, combined with the parallel chains of huge snow-covered mountains, gives in winter to central Spain nearly as low a temperature as that of northern Europe. That such is the case is evidenced by the vegetation, which is not more southern than the vegetation of the less favoured regions of England.

The coast-line, especially the south-eastern coast-line, presents very different physical conditions. Bathed by the warm Mediterranean Sea, exposed in full to the powerful south-eastern sun, protected from the north north-west and south-west winds by the entire bulk of the mountain land of Spain, it is really a southern region, as its vegetation testifies. There are other influences which tend to modify its climate. It is all but a rainless tract, and certainly the driest region in Europe. I have never met with a thoroughly satisfactory explanation of this fact, which most observers and writers announce without trying to explain. I was in Spain in May 1868, and previously to entering that country I had carefully explored Algeria, from Fort Napoleon in the east to Oran in the west, and from Algiers to the margin of the Desert of Sahara. The meteorological conditions there existing and recognised gave me, I believe, the key to this paucity of rain on the east coast of Spain.

The presence of the Pyrenees and of the mountain chains of central Spain at once explain the absence of rain on the eastern coast, with north, north-west, and even south-west winds. The rain-clouds are arrested in passing over these elevated regions, and their moisture is squeezed out. But why should not the north-east and south-east winds, which so frequently reign in the Mediterranean, and which pass over vast tracts of water before they reach the east coast of Spain, bring their burden of rain to the mountain-fringed shores of Spain? I be-

\* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

lieve that the explanation is to be sought for in Africa, in the Desert of Sahara. This immense tract of sunburnt sand, which covers a considerable portion of the continent of Africa, may be considered one vast furnace. The atmosphere heated on its surface is constantly rising up into the higher atmospheric regions, and thus creating a vacuum. To fill this vacuum, the Mediterranean winds, north, north-east, and east, are pulled down before they reach the coast of Spain, probably within fifty or a hundred miles of it. Thus diverted, they pass over the Algerine or Mount Atlas Switzerland; there deposit their moisture, making it in winter and spring a moist verdant region, to lose themselves in the great sandy desert.

That the boisterous winds which make the western Mediterranean so troubled a sea in winter, are thus diverted, is certain. The coast of eastern Spain is proverbially a calm sea. At Alicante there is a saying that their sea is "a sea for women and children." The steamers from Marseilles to Algiers pass between the Balearic Islands, about seventy miles from the mainland, and constantly in winter they have to contend with very bad weather. As constantly do they escape from it by steaming east to the Spanish coast. This is so much the case, that a detention on the Spanish coast going or coming from Algiers is a common, at some seasons a regular, incident of the voyage.

Whatever the explanation, the fact is certain that from Malaga to Barcelona, on the east coast, there is very little rain, not more than forty days in the year, often not that—much less than on the Genoese Riviera, also an exceptionally dry region. The winter temperature is also so exceptionally mild that there can never be more than a few degrees of frost, as evidenced by the flourishing existence of orange and lemon trees, of subtropical palms, and of other plants which cannot stand more than a few degrees of winter frost. I only found, however, at Malaga, flourishing in the open air, the cool stove plants, heliotropes, lantanas, pelargoniums, etc., which I and my neighbours grow in our gardens, unprotected, at Mentone and in the more sheltered parts of the Riviera. At Murcia and Valencia, these plants were grown in pots and placed under cover in winter. The conclusion which I legitimately draw is, that the winter temperature is as warm, indeed a shade warmer, at Malaga than at Mentone, but that, on the rest of the Spanish coast, the winter temperature is rather lower than at Mentone and the more sheltered regions of the Riviera. The climate, soil, and vegetation are, however, the same in both regions. Medically speaking, therefore, they are suited to the same morbid states, to all who require a dry, sunny, bracing, stimulating, mild winter climate. Malaga would, thus, be one of our most valuable resorts were it not for its filthy, unhygienic state, which renders it unfit for the residence of a healthy, and still more of an unhealthy person. Although most sincere in the expression of my convictions on this score, and most anxious to be impartial, it may be thought that a prepossession in favour of my winter home makes me a prejudiced witness. I therefore refer to the testimony of Dr. Madden, an enthusiastic admirer of the climate of Malaga. In a pamphlet entitled *The Climate of Malaga in the Treatment of Chronic Pulmonary Disease*, Dublin 1864, he says very graphically, and very explicitly:—

"The hygienic condition of Malaga is as defective as it can well be. In a great many of the houses there is no provision for sewerage of any kind; and even in the more civilised part of the city, in the hotels on the Alameda, the drainage is very bad indeed. The main sewers, which run under the principal streets, are choked up by the decomposing accumulation of years, and, being provided with immense square openings through which the dirt and rubbish is thrown into them, in the centre of the streets, the mephitic gases evolved below freely escape into the atmosphere of the narrow lanes of the city. The bed of the Guadalmedina is really the main sewer of Malaga; and as for nearly ten months annually it is little more than a wide dry bed of gravel, being dependent on the torrents in winter for its purification, the odour it exhales in warm weather renders a residence near it as disagreeable as it is unhealthy. The connexion between epidemic disease and bad sewerage is, I think, very well illustrated in Malaga, which has at all times been remarkable for the prevalence of zymotic disease. I have collected from the older Spanish writers notices of no less than twenty-two epidemic pestilences, some of which almost depopulated the city between 1493 and 1804. The earlier of these seem to have been epidemics of genuine Oriental plague, and the latter generally assumed the form of yellow fever. Of late years, since 1834, these pestilences have not appeared, but their place has been taken by Asiatic cholera, which has several times ravaged the town."

Such is the description of this favourite resort for consumptives, given by Dr. Madden, himself an ardent supporter of it. May I not ask, in cool, sober, common sense, whether it is not sheer insanity to send miserable invalids, young and old, already stricken with disease implying decay of vitality, lowered organic power, to a town where the de-

fective hygiene of the cities of the middle ages reigns supreme; where filth-engendered pestilence stalks abroad day and night, as in former days; where the Oriental plague is succeeded by yellow fever, and yellow fever by Asiatic cholera?

There are other towns on the east coast of Spain—Murcia, Elche, Alicante, Valencia, Seville—but in none of them is there any suitable accommodation for invalids. The hotels are merely inns of a third or fourth class, frequented by, and supported by, commercial travellers, and situated in the middle of these unhealthy cities. Tourists can put up with them, but they are not fit for real invalids. In the course of time, commercial enterprise will no doubt provide suitable accommodation in this really good and favoured climate of the east coast of Spain. But in the meanwhile, real invalids, who require a dry, bracing, sunny, mild, winter climate, had better keep to the Genoese Riviera. For further details on the subject of this paper, I must refer to the last edition of my work on the *Winter Climate of the Mediterranean*.

## METEOROLOGY AND CLIMATE OF PLYMOUTH.\*

By J. MERRIFIELD, Ph.D.

MR. PRESIDENT AND GENTLEMEN,—Believing as I do that climate and health are very closely interwoven, I must urge this as an excuse for bringing forward the subject of the meteorology and climate of Plymouth; and, as I am unaware of any other consecutive registers of meteorological phenomena kept in the neighbourhood, I beg to offer to the Association the few deductions that I have drawn from my own observations, although I could wish this honour had fallen into abler hands.

In speaking of the climate of any place, I must guard my hearers against using that term indiscriminately with weather.

*Weather* expresses the condition of the atmosphere at any particular time in a certain place.

*Climate* means the condition of a country with regard to its meteorological phenomena generally, or it is the mean or average of all weathers taken for a very long period. Weather is changeable; climate is uniform. Time enters as a factor in weather; from climate time has been eliminated. "Climates are different in different places; whereas the weather, though changeable in any one place, may be the same at the same time in many places."

My recorded observations extend over about seven years; viz., since October 1864, and the deductions I may draw should be received with all the caution due to the short time during which I have registered systematic data. Then, again, by using check instruments I have found reflected heat where I little expected, and hence sometimes too high a maximum has been recorded; and at others I have left thermometers exposed by night, when by radiation under a cloudless sky, with a small amount of vapour in the atmosphere, I have registered too low a minimum. As an instance of this, I have several times found ice formed on the top of my house, when a screened thermometer in the open air close by has not sunk lower than 35 deg. Fahr. The material of which the screen is composed, the colour of the paint used, and a countless number of so-called trifles, tend to introduce discrepancies between observers who are otherwise as careful as it is in man's nature to be. Again, among observers I believe proper allowance has not been made for the character of the soil near which observations have been taken: thus on Dartmoor, near the peat-bogs, the heat from the sun is absorbed by the black marshy soil, and is at once transformed into what scientific writers of the present day call "potential energy," by converting the water into vapour; but I have become sunburnt on the moor, when a shaded thermometer there has stood many degrees below one under similar circumstances in Plymouth, where the sun's heat has been reflected and radiated from our lime-stone soil. No doubt part of the effects of the direct rays of the sun was due to the small amount of vapour in the atmosphere on the high ground of Dartmoor, whilst in the air at Plymouth more vapour is found.

I have felt bound to make these introductory remarks; because, if any observer compare his observations with mine, attention to little matters may reconcile many apparent discrepancies.

In comparing my observations, I find the mean temperature of Plymouth to be 52.31 deg. Fahr. This mean would obviously be best found by recording for a long period twenty-four hourly observations and taking their average; but Mr. Buchan, the Secretary of the Scottish Meteorological Society, has shown that the mean between the maximum and minimum between every day in the year is too great only by a frac-

\* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

tional part of a degree; and this is the method which I have adopted. I find that the mean temperature corresponds to the mean of those taken at 8 A.M.; this, I believe, is much earlier than is generally supposed. The months of April and October give nearly the same means as the year.

Our hottest months are June, July, and August, when the averages are 61.01 deg., 64.5 deg., and 62.8 deg. Fahr., thus showing July to have the advantage. Our coldest months are January and March; the averages being 42.2 and 43.4 deg., the latter, on the whole, being colder than either December or February. Like every other place, we have some extreme readings; but these in Plymouth, as in all the south-western district, are comparatively rare. The maximum temperature in the shade which I have recorded is 93 deg. Fahr. on June 27th, 1866. The minimum is 14 deg. Fahrenheit, on December 27th, 1869. The maximum should be received with caution, because I am afraid heat must either have been reflected or radiated from surrounding substances. I have many instances of the temperature reaching from 85 deg. to 90 deg. I find that the maximum for the day is generally from 2.30 to 3.30 P.M.; but the time is modified from the effects of clouds, etc.; so much so, that I have occasionally found the maximum as early as 8 to 9 A.M., and as late as 7 P.M. Our mean maximum is 60.01 deg.; our mean minimum 44.61 deg. Fahr.

The average difference between our wet and dry bulb thermometers is 2.6 deg. Fahr. Very frequently at 8 A.M., and even throughout the day, we find our dry and wet bulbs indicating the same temperature; thus showing the atmosphere to be completely saturated with aqueous vapour. I take this to be a phenomenon common to the whole south-western district, because with a south-west wind coming from a warm ocean the air must be highly charged with moisture; and when it is cooled by contact with the land complete saturation takes place, and we get drizzling rain lasting for hours, perhaps days, and yet the rainfall for that time is comparatively small. Then, again, on June 22nd, 1865, I found 15 deg. between the readings of the bulbs; the dry being 78 deg., the wet 63 deg., and the barometer 30.336 inches. This would give the dew-point, or temperature at which dew will begin to be deposited, 52.6 deg. Fahr., the relative humidity 41, complete saturation being 100, and 4.3 grs. of vapour in a cubic foot, whilst it would take 6.0 grs. more of vapour to saturate the air. This is the least humidity I have ever observed in Plymouth, and was after several days of continuous easterly winds. In June month I find, as a rule, the least relative humidity, and in November the greatest. The readings of the dry and wet bulbs should be carefully attended to in all districts, as by means of such readings, with Glaisher's tables, the dew-point may always be calculated and the minimum temperature on the ground predicted very nearly. Knowing that this is of great value to all such as have tender plants which will not bear low temperatures, I may also point out that, with the aid of the hygrometer (as it shows the temperature and dryness or humidity of the air), an artificial climate may by very simple means be produced; and those whose circumstances in life or condition of health prevent them from seeking a climate suited to their peculiar constitution can, to a great extent, make up for the deficiency by the assistance of this instrument.

I am aware that the existence of the Gulf Stream has been questioned by many eminent men; but I have never seen another valid explanation for the finding of articles of West Indian produce on the western shores of the British Isles, France, and Norway. A few of these, by the kindness of the Lord Secretary, Dr. Littleton, I am enabled to exhibit: these were, I believe, found on the coast of Cornwall. Then, again, many one of the very highest authorities on this and kindred subjects positively asserts that the water of the Gulf Stream differs from other waters "not only in colour, transparency, and temperature, but also in specific gravity". Again, by comparing temperatures, he proves that the ocean reaching the western shores of the British Isles is much warmer than the latitude would indicate without such a current; and Professor Wyville Thomson (one of the principals associated with Dr. Carpenter in the *Porcupine* Expedition of 1869), in his address delivered before the Meteorological Society of Scotland in July last, gives corroborative proof of this superior temperature of the ocean coming up from the south-west (*Nature*, vol. ix, pp. 251 et seq.). Until these observations are proved untrue, I for one shall accept the deduction. Whether there be a Gulf Stream or not (but of whose existence I have no doubt), from the fact that the temperature of the ocean is higher than the latitude warrants, and from the great specific heat of water, our winters must be ameliorated and our climate rendered more humid than it otherwise would be, making in contrast very favourably in temperature with ports and watering places on the eastern shores of Britain.

I find the greatest range of the thermometer to be in the summer months of June and July, when the average range is above 20 deg. Fahr. The least range is during the winter months of January and February,

when it is less than 10 deg. Fahr. I can account for this only by the fact that the vapour in the atmosphere during the summer months is far more attenuated or rare than in the winter months; and hence the heat-rays from the sun are absorbed more in winter than in summer, whilst radiation from the earth is prevented from the same cause during the same time. This is simply an illustration of Professor Tyndall's theory of absorption and radiation. The greatest daily range of temperature I have ever registered was on April 27th, 1865, when it was 44 deg.—viz., the minimum 42 deg. and maximum 86 deg.—and on June 20th and 22nd, 1865, and June 27th, 1866, when the range was 40 deg. on each occasion. In very many instances I have found it to be more than 30 deg. Fahr. As a contrast to these, on December 22nd last, 1870, I found the daily range to be but 2 deg. Fahr.—viz., the minimum 26 deg., maximum 28 deg. Fahr.—and on several occasions the daily range has been but 3 deg. Fahr.; the maximum being about 30 deg., and minimum about 47 deg. Great daily ranges are indicative of dry weather, whilst small ones show rain or great cold. The connexion between great daily ranges of temperature and health, as affected by certain diseases, would be an interesting problem for some medical man with time on his hands to solve; i.e., whether great ranges of temperature on several successive days tend to increase the mortality caused by some diseases: if so, then the treatment at such times is obvious, and localities with small extremes of temperature for invalids with these diseases should be chosen. Another question is, do extreme temperatures, even if they last for some days, affect health as much as great daily ranges of temperature?

The atmospheric pressure, as shown by the barometer, has fluctuated between 30.822 inches, the maximum on 15th Dec., 1865, and 28.500 inches, the minimum on the night of 10th January, 1866; a difference of pressure amounting to about 2½ inches of mercury. These readings are reduced to the mean sea-level at 32 deg. Fahr. I have found the pressure seldom to fall below 29 inches. This occurred on four mornings in 1865, two in 1866, three in 1867, three in 1868, three in 1869, and not at all in 1870. The month of greatest mean pressure is June, the average being 30.120; the month of least mean pressure is January, the average being 29.844. The mean pressure for the whole time is 29.953.

We next come to speak of the winds. I find in the six complete years of which I have records, that on 407 mornings we had wind from north to east, on 444 from east to south, on 671 from south to west, on 564 from west to north, and 97 mornings calm; whilst from sickness, absence, and other causes, no register was made for 8 mornings. These numbers give 18.58 per cent. for the wind from north to east, 20.27 from east to south, 30.62 from south to west, 25.74 from west to north, and 4.42 per cent. calm; thus winds with a westerly tendency or calm amount to 60.78, whilst those with an easterly tendency are only 38.25 per cent. The months in which we have the greatest amount of easterly winds are March, April, and May; those with the greatest amount of westerly winds are February and July; whilst those with most calms are April and September. The strongest winds blow almost invariably from south to west, and increase in violence as they veer—that is, as they follow the course of the sun. This, no doubt, is occasioned by the rotation of the earth. Plymouth is pretty well sheltered by high ground, except in the south, and is especially so from north to east; hence the full force of the wind from that quarter cannot be felt in the town, and the proverbially baneful east wind is robbed of its sting.

Rain next claims our attention. If not less than ⅓ of an inch fall in twenty-four hours, it is usually classed as a rainy day; it should be as a day on which rain falls. The number of days on which rain, snow, or hail fell was 189 in 1867, 168 in 1868, 177 in 1869, and 118 in 1870. The quantity in 1869 was 30.01 inches, and in 1870 was 24.11; and these are the only years in which I have kept a register of the rainfall.

From the last quarterly weather report issued from the Meteorological Office, taking the average of the five years from 1866 to 1870 (both inclusive), I find that the mean annual rainfall of Plymouth is 38.95 inches; January contributing 5.32 inches, September 4.92, and December 4.58 inches, these three months being those in which most rain falls. June contributes but .77 inch on the average, or only 2 per cent. of the rainfall, this being the least. We sometimes experience very heavy showers. These, in my opinion, are the results of electrical discharges. The heaviest shower I ever witnessed was on Saturday, July 29th, 1871, from 9.30 to 10 A.M., when in less than half-an-hour about three-quarters of an inch was registered. These very heavy rains are of rare occurrence. The humidity of a district should be judged more by the number of rainy days than by the quantity of rain which falls; because fine rain falling for several successive days, not amounting to nearly as much as a single heavy shower, will render a climate more moist than another where the rain falls heavily and then stops. I have the authority of Mr.

Scott, F.R.S., for saying that the amount of rainfall is well determined in scarcely a large town in England; and in Plymouth the gauges are peculiarly misplaced, being either on the tops of houses where the draught through the streets interferes considerably with correct results, or in sheltered spots. In my own case, the gauge is situate on the edge of a vertical wall twenty-six feet six inches from the ground, and is sheltered from S.S.W. to W. by N. by another house. Experiments conducted by Mr. Chrimmes of Rotherham, and published by Mr. J. G. Symons in his *British Rainfall*, show that the amount decreases with elevation; and for the height of my gauge about 16 per cent. should be allowed. From the Rotherham experiments, extending over fifty-six months, Mr. Strachan, F.M.S., has calculated that the mean inclination of rain is 42 deg. from the vertical (*Brit. Rainfall*, 1870, p. 53); and, as the highest part of the chimneys of the adjacent house makes an angle of 45 deg. with the vertical, there can be but little effect from its position, although with a strong wind some rain must be lost to my gauge. Then, again, I have observed that, when the rain accompanies a south-east wind, the latter strikes against the wall, is forced over it, and carries the rain away from the gauge. From these causes it would be manifestly unfair to draw comparisons between the amount as measured by me and the rainfall at other places. For example, at Tavistock, about fourteen miles due north, and nearer the moor, the measurement is many inches more than at Plymouth, whilst at Dartmoor prisons nearly double the amount is registered. Although so near the sea, and in the path of the counter trades, yet we sometimes, but rarely, experience a want of rain; for example, from March 18th to July 2nd, 1870, during which time, if we omit a thunder-shower on the 12th May, only 1.3 inches of rain fell in 106 days: in fact, the whole year was very dry, there being but  $\frac{1}{3}$  of the average rainfall. We go many days in the year without a sight of the sun, the sky being completely overcast; and it is but seldom our atmosphere is free from cloud.

I have said nothing about the ozone at Plymouth, because I have kept no record of the amount; and until some method be adopted for measuring the amount of nitric and other acids in the atmosphere, with the quantity of air which passes over the test-papers, no reliance can be put in the amount of ozone measured by the colour given to these papers. When I speak of ozone, I mean that peculiar condition of oxygen which renders it more readily able to combine with other elements, and thus it neutralises what obnoxious gases the atmosphere may contain. From its powerful oxidising properties, it is generally considered an allotropic condition of oxygen; and Professor Tyndall

says it may be an aggregation of atoms of oxygen into molecules. Seeing that electricity is generated in such large quantities on the sea-shore, and more especially where the sea breaks in large rollers on the beach, and as it is known that ozone is produced simultaneously with electricity, no doubt we have a large amount in the south-west district. Then, again, it is known that sea-water holds from  $\frac{1}{10}$  to  $\frac{1}{20}$  its volume of air in solution; but the air in the sea contains 32 per cent. of oxygen, instead of 21 per cent. as the atmosphere over land does. By agitation, we may reasonably suppose a portion of this air surcharged with oxygen is given off, and during storms the quantity is most likely much increased and the effects on health are highly beneficial. This I take to be one of the chief reasons why a seaside residence is so conducive to improved health among invalids. Now in Plymouth and in the whole south-western district, we have the broad stormy Atlantic whence we draw our supply of this element; whilst on the east coast the storehouse is narrowed into the comparatively narrow North Sea or German Ocean.

The months of January and November seem to bring more severe atmospheric storms than any other months; but Plymouth appears to enjoy an immunity from electrical storms, thunder and lightning being but seldom known; thus whilst electricity may be generated on our coasts, and the sky often bears tokens of the existence of electricity in large quantities, yet it is generally carried inland before a violent discharge takes place. I have no doubt that a large quantity is silently discharged through our damp atmosphere, and is unperceived by us.

Our average barometrical pressure being 29.953, our temperature of the air 52.31, and difference in the wet and dry bulb thermometer 2.6, we have an average dew-point of 47 deg. Fahr., relative humidity, 82.4, and 3.7 grains of aqueous vapour per cubic foot in the atmosphere. Hence I conclude that our town is warm and moist, arising from the large proportion of westerly winds (the return trades) which blow over us; we have few extremes of temperatures, few electrical or atmospheric storms; a cloudy sky, but not a large rainfall.

The records and diagrams from which I have drawn my conclusions now lie on the table for the inspection of anyone who feels an interest in the subject; and I would particularly draw the attention of such to the illustration of the fact that, with a low barometer, we get a high temperature, and *vice versa*. One more illustration is worth noticing; that, when we have a fall of the barometer, and the dry and wet bulbs are far apart, wind is foretold; but if the readings of the bulbs approach with a falling barometer, then rain may be expected.

Averages of Meteorological Register, extending over Six Years, from 1865 to 1870 (both inclusive).

## AN ANALYSIS OF STATISTICS OF LATERAL LITHOTOMY.\*

By the late WILLIAM KEITH, M.D., M.R.C.S.E.,

Senior Surgeon to the Royal Infirmary, Aberdeen;  
Lecturer on Clinical Surgery; etc.

CASE CVII.—W. Thompson, aged 74, a mason, was admitted on June 28th, 1852; and was operated on August 14th. He was at the time, and had been for some time before, suffering from diabetes

mellitus. The stone weighed 4 drachms 1 scruple, and measured 1½ inches by ½ inch by 1½ inches. Suppression of urine came on, and he died comatose on the 25th. At the *post mortem* examination, a considerable amount of effusion was found between the membranes of the brain and in the lateral ventricles. The lungs were healthy, except that they were somewhat emphysematous at the apices. The intestines and bladder were natural. The wound in the latter was nearly closed. The kidneys were both diminished in size and much diseased.

CASE CXVI.—W. Nicol, aged 79, miller, was admitted on November 11th, 1853, and was operated on February 11th, 1854, when four

\* Concluded from page 322 of last number.

stones, weighing  $4\frac{1}{2}$  drachms, and measuring each 1 inch by  $\frac{1}{2}$  inch by  $\frac{1}{2}$  inch, were removed. He gradually sank, and died from age and exhaustion of nature's powers by a small pelvic abscess, on March 11th, four weeks after the operation. The whole of the contents of the abdomen were natural, the only thing to account for his exhaustion being a small deposit of pus around the lower end of the rectum.

CASE CXXIV.—George Sanderson, aged 68, a farmer, was admitted on August 13th, 1855, and was operated on August 25th. Seven calculi were removed, weighing 1 ounce 3 drachms, and the largest measuring  $1\frac{1}{2}$  inches by  $\frac{3}{4}$  inch by 1 inch. He went on well till the morning of the third day, when suppression of urine supervened, and he died comatose at half-past seven on the evening of the 28th. The third lobe of the prostate had come away in the forceps at the operation. The kidneys were not much altered in structure; the bladder was thick and diseased; and the prostate enormous.

CASE CXXV.—John Connor, aged 64, a seaman, came under treatment on September 24th, 1855, and was operated on October 16th. The stone weighed 7 drachms, and measured  $1\frac{1}{8}$  inches by  $1\frac{1}{8}$  inches by  $1\frac{1}{2}$  inches. He died of pyæmia, on October 27th, 1855, eleven days after the operation.

CASE CXXVI.—James Sangster, aged 74, farmer, came under treatment on October 20th, 1855, and was operated on December 4th. Two stones were removed, weighing 3 ounces 3 drachms, and the larger measuring 2 inches by 1 inch by  $1\frac{1}{8}$  inches. He died on December 8th, exhausted by previous suffering.

CASE CXXVIII.—John Cockburn, aged 58, crofter, was admitted on June 18th, 1857, and was operated on July 4th. The stone weighed 4½ drachms, and measured  $1\frac{1}{2}$  inches by  $\frac{3}{4}$  inch by 1 inch. He went on well till the evening of July 8th, when he complained of pain in the right knee, which persisted, spite of treatment. The whole leg became swollen; he gradually became weaker and weaker, and died on the morning of July 14th. At the *post mortem* examination, the only marked disease discovered was in the right knee-joint, which contained about two ounces of thick yellow pus, but showed no signs of previous organic disease.

CASE CXXXIX.—James Moor, aged 62, sawyer, was admitted on June 22nd, 1857, and was operated on July 4th. The stone weighed  $7\frac{1}{2}$  drachms, and measured 2 inches by  $\frac{3}{4}$  inch by  $1\frac{1}{8}$  inches. The day after the operation, he complained of a pain in the right iliac region, which persisted. He gradually grew weaker, and died on July 7th. At the *post mortem* examination, the intestines were found congested, especially in the right iliac region, where they adhered to the wall of the abdomen. Both kidneys were fatty. Pus was infiltrated into the cellular tissue around the entrance of both ureters into the bladder.

CASE CXLVI.—John Collie, aged 65, ropemaker, was admitted on December 15th, 1857, and was operated on December 24th. The stone weighed 1 ounce, and measured  $1\frac{1}{8}$  inches by  $\frac{3}{4}$  inch by  $1\frac{1}{8}$  inches. He went on well till January 5th, when diarrhoea came on, followed by hiccough; and these, persisting, so weakened him that he died exhausted after a rigor on the evening of January 10th, seventeen days after the operation. No *post mortem* examination was allowed.

CASE CXLVII.—W. Mackie, aged 72, blacksmith, came under treatment on February 3rd, 1858, and was cut on February 10th. The stone weighed 7 ounces 5½ drachms, and measured  $3\frac{1}{4}$  inches by  $1\frac{1}{2}$  inches by  $2\frac{1}{4}$  inches. The case went on favourably for six days, when the urine became scanty; and he died on the eighth day (Feb. 18th) with symptoms of uræmia. No inspection was allowed.

CASE CXLIX.—Robert Garioch, aged 75, farmer, came under treatment on May 22nd, 1858, and was operated on May 29th. The stone weighed 1 ounce 5 drachms 1 scruple, and measured 2 inches by 1 inch by  $1\frac{1}{2}$  inches. The internal incision was thought to be too small, and, though he was under chloroform, a remora was noticed before he could be put to bed. Yet he continued to go on favourably for a few days; but, in consequence of his using great freedom in getting up and going about, disease supervened in the pelvis, from the effects of which he died on the tenth day (June 8th). No inspection was had, as he was fifty miles from town.

CASE CLV.—John Pyper, aged 30, blacksmith, was admitted on December 13th, 1858, and was operated on January 8th, 1859. The stone weighed 1 ounce, and measured 2 inches by  $\frac{3}{4}$  inch by  $1\frac{1}{2}$  inches. Symptoms of inflammation of the bowels came on, though not very acutely; and he gradually sank, and died on January 16th, eight days after the operation. At the *post mortem* examination, a large quantity of pus, mixed with flakes of lymph, was found in the peritoneal cavity. The surface of the intestines was not congested, but had lost its usual glistening look. The kidneys were both much diseased; there were several small abscesses in each, and a calculus in the pelvis of the left kidney.

CASE CLVII.—George Gordon, aged 70, plasterer, came under treatment on June 22nd, 1859, and was operated on July 19th. Six calculi were removed, weighing  $3\frac{1}{2}$  drachms, and the largest measuring  $\frac{3}{4}$  inch by  $\frac{3}{4}$  inch by  $\frac{1}{2}$  inch. The artery of the bulb was cut at the operation, and was the cause of secondary hæmorrhage to a limited extent, though not seen in any marked manner at the time of the operation. Suppression of urine came on, and he died on July 21st, three days after the operation. At the *post mortem* examination, three calculi were found in the right kidney. Both kidneys were much diseased.

CASE CLIX.—Alexander Angus, aged 31, a farm-servant, was admitted on November 14th, 1859. His urine was albuminous, and he had pain in the lumbar region, present for months; but long rest in the hospital so improved his looks, so abated the pain and the presence of albumen, that the operation was ventured on May 12th, 1860. The stone weighed 1 ounce 5 drachms, and measured  $2\frac{1}{2}$  inches by 1 inch by  $1\frac{1}{8}$  inches. Neither pain nor pulse gave evidence of action being present in any unusual degree; yet he died on May 18th, six days after the operation, with symptoms of uræmia. There was exudation of pus and lymph on the left side of the pelvis, in no apparent way connected with the wound, yet in contact with the peritoneal coat of the bladder. One large and two small calculi were found in the right kidney, that organ being wasted almost to a cyst.

CASE CLXIV.—Alexander Davidson, aged 66, crofter, was admitted on January 28th, 1861, and was operated on February 2nd. The stone weighed 1 ounce, and measured  $1\frac{1}{2}$  inches by 1 inch by  $\frac{1}{2}$  inch. Previously to the operation, the urine was of specific gravity 1020, and there was no trace of albumen in it. Though the urine was at first scanty after the operation, yet it had become copious; and at 9 P.M. on the evening of February 7th he felt well and cheerful. At midnight he had a rigor, followed by convulsions, which ended in death at half-past four on the morning of February 8th. The right kidney weighed 9 ounces, the left 18 ounces; and both were filled with cysts, and disorganised. A renal calculus obstructed one of the ureters close to the kidney.

CASE CLXX.—Alexander Henderson, aged 47, crofter, was admitted on October 7th, 1861, and was operated on on the 23rd. The stone weighed 4 ounces 3 drachms, and measured  $2\frac{1}{2}$  inches by  $1\frac{1}{8}$  inches by  $2\frac{1}{8}$  inches. He went on favourably till November 1st, when the tongue became somewhat dry. His pulse was quiet, and his belly natural; but he gradually grew weaker, and died at 11.50 P.M. on November 1st. The *post mortem* examination revealed purulent deposits behind the peritoneum, all over the left side of the pelvis.

CASE CLXXII.—W. Gordon, aged 76, crofter, was admitted on March 26th, 1862, and was operated on March 29th. Three stones were removed, weighing  $7\frac{1}{2}$  drachms, the largest measuring 1 inch by  $\frac{3}{4}$  inch by  $\frac{3}{4}$  inch. The prostate was enormous. He went on favourably for a fortnight, the urine coming almost entirely *per urethram*; but, on attempting to get out of bed without help on the fourteenth day, he fell violently on the floor, and was much injured by the shock. His appetite failed, which, in his wasted frame and feeble constitution, coupled with seventy-six years of age, sufficed to kill him. On *post mortem* examination, the kidneys were found of small size, but perfectly healthy in structure. The calculi removed were each shaped like a right-angled triangle.

CASE CLXXV.—James Fraser, aged 66, a mason, was admitted on July 17th, 1862, and operated on July 23rd. The stone weighed 1 ounce, and measured  $1\frac{1}{4}$  inches by 1 inch by  $1\frac{1}{4}$  inches. He died on August 2nd, from cellulitis in the pelvis and pyæmia. No inspection was had, in consequence of my absence from home.

CASE CXCI.—George Gauld, aged 73, farmer, came under treatment on July 15th, 1864, and was operated on August 16th. Twelve calculi, of the size of French beans, weighing 9 drachms, were removed. Diarrhoea, accompanied by hiccough, set in severely on the third day, without another unfavourable symptom; the urine being clear and copious; the belly soft and easy; the pulse 96, compressible, full, and soft; the tongue moist, though partly furred; and the appetite tolerable. Yet, in spite of treatment, the looseness continued; and he sank comatose at 6 P.M. on the 4th day (August 20th.). No *post mortem* examination was had, his residence being forty miles distant from Aberdeen.

CASE CXCI.—Robert Cran, aged 70, farmer, came under treatment on October 12th, and was operated on October 12th, 1864. The stone weighed 7 drachms, and measured  $1\frac{1}{8}$  inches by  $\frac{3}{4}$  inch by  $1\frac{1}{8}$  inch. It being believed that there was one hour and twenty minutes' secretion in the bladder, and that more was flowing or entering, it was feared at the moment that the inner incision would prove too free, from cutting into an empty bladder; and so it turned out, the patient dying on the evening of the third day, from the effects of urinary

infiltration. No *post mortem* examination was had, in consequence of his residence being fifty miles distant from Aberdeen.

CASE CXCIII.—James Clarke, aged 55, mason, came under treatment on March 6th, 1865, and was operated on April 1st. The stone weighed 2 ounces  $1\frac{1}{4}$  drachms, and measured  $2\frac{1}{4}$  inches by 2 inches by 1 inch. With a quiet pulse, and urine both clear and copious, he went on favourably for eight days, the tongue only being dry; yet his desire for food was natural. On the ninth day, the pulse quickened a little; but there was no tenderness or local symptom anywhere, and he still took his food. On the twelfth day, he became faint, after sitting up in bed; and, continuing feeble, he expired on the evening of the thirteenth day (April 13th). Inspection revealed a collection of thick pus in the cellular tissue around the wound and neck of the bladder. The viscera of the abdomen were quite healthy. The coats of the bladder were thick and chronically inflamed.

CASE CXCIII.—David Stewart, aged 79, farmer, was admitted on July 7th, 1866, and was operated on July 14th. The stone weighed  $7\frac{1}{2}$  drachms, and measured  $1\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches. The patient was a large-built man, with a deep perinæum and a large cartilaginous prostate gland; yet the blunt gorget and chloroform made the operation easy. He went on well till the evening of the fifth day, when, after some freedom used in getting out of bed, he had a rigor, quickly followed by tenderness in the right pubic region, where a reducible hernia existed. The secretion of urine at the same time became nearly suspended. Leeches to the groin abated the pain and tenderness; but, although the general symptoms seemed at times cheering, the urine never came in natural quantity, and he gradually sank on the eighth day. Inspection revealed pus in the hernial sac, and a pinkish blush on the adjoining peritoneum. The liver was nutmeggy and friable; the kidneys were much diseased; the bladder sacculated and greatly hypertrophied.

CASE CCV.—James Sim, aged 75, farm-servant, was admitted on February 13th, 1867, and was operated on February 28th. The stone weighed 5 ounces 7 drachms, and measured 3 inches by  $1\frac{1}{2}$  inches by  $2\frac{1}{2}$  inches. He went on most favourably till the sixth day, when, the bowels not having moved, a moderate dose of castor-oil was given. It operated twice comfortably; but, from the moment it did so, he felt weak, the urine began to flow less copiously, and he became drowsy. Sinapisms were applied to the nape of the neck, and turpentine stupes to the loins. Brandy and spirits of nitre were given freely; but the secretion of urine never returned in quantity; the pulse, never before above 60, now quickened; his strength failed; and he quietly expired at 3 A.M. on March 7th. Inspection revealed no very unusual appearances in the wound or its surroundings. The walls of the bladder were thickened and rugous, and congested on its inner surface. The fundus of the bladder outside the cellular tissue looked as if exudation of lymph had taken place, and was undergoing the process of softening and becoming purulent; but no adherent or reddened spot could be detected on the intestinal or pelvic peritoneum. The kidneys were small and diseased; the ureters were as large as a man's thumb; and the pelves of both kidneys widely distended.

CASE CCXVI.—John Fraser, aged 67, crofter, was admitted on June 5th, 1869, and was operated on on June 16th, when a calculus weighing 1 ounce, and measuring  $1\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches by  $\frac{1}{2}$  inch, was removed. He died on the eleventh day after the operation, without one untoward symptom connected with the kidneys or bladder. Pain at the pit of the stomach, and latterly coffee-ground vomiting, preceded his death. *Post mortem* examination revealed cancer of the pylorus and ulceration of the mucous membrane of the stomach. It turned out, on inquiry, that he had laboured many months under that disease, but had studiously concealed it.

CASE CCXIX proved fatal two days after the operation. No details are given in Dr. Keith's tables, further than the weight of the stone and the date of death.

## EMBOLISM OF THE CENTRAL ARTERY OF THE RETINA.

By C. S. JEAFFRESON, Assistant-Surgeon, Newcastle-on-Tyne Infirmary.

ALTHOUGH most ophthalmic surgeons must have seen cases of embolism of the central artery of the retina, they are still of sufficient rarity to be worth putting upon record.

R. M., aged 28, whilst following his usual occupation as a brick-layer, became suddenly conscious of the rapid approach of blindness in his right eye. He described the blindness as having commenced in the centre of the field of vision, and gradually spread towards the periphery

with such an amount of rapidity that, in a few moments, total darkness was produced. He left his work in great alarm, and the following day presented himself to me.

On examining the state of vision I found the left eye normal. In the right eye the whole field of vision was obscured, with the exception of a small portion in which it was highly amblyopic, recognising only obscurely the presence of the finger when held up. After his pupils had been thoroughly dilated with atropine, I examined him with the ophthalmoscope. The size, colour, and shape of the optic disc, the reflection from the fundus, and the condition of the vessels on the left side, were normal. On the right side, the optic disc was unaltered in colour, but the retinal arteries were reduced to the most minute threads, the veins congested, and for some distance surrounding the macula lutea there was a paleness of the fundus which made the redness of that spot stand out in prominent contrast. On searching for signs of cardiac disease, I found that, although there was no murmur of any kind, there was distinct evidence of hypertrophy, and that the heart's action was irregular and intermittent.

The chief peculiarities in this case are, the manner in which the blindness supervened, and the retention of a certain amount of vision in a very small portion of the field. The former I believe never before to have been noticed; and the latter, though noticed, not satisfactorily explained.

The only explanation I can offer of a portion of the field of vision still retaining sensibility is, that some spot in the retina must derive its blood-supply, partially, at least, from some other source than the retinal artery; and if vision improve, we must expect to find it increasing the area of this spot, where if any collateral circulation is established, we may most reasonably look for it.

## WASP-STINGS.

By C. D. H. DRURY, Pulham St. Mary.

DURING the last fortnight or three weeks, I have been called upon to treat no less than seven cases of illness arising from the stings of wasps.

On August 21st, my cook, while making pastry, was stung in the forefinger of the right hand by a wasp. In less than half an hour she felt exceedingly depressed and weak, and complained of severe headache; and her hand was so swollen that she could not bend her fingers. The eyes were red and bathed in tears; the face puffy, swollen, and dusky; and she was completely covered with an urticarious eruption. I could not find any remnant of the sting in the finger, and only with difficulty the place where the sting had entered. I ordered her at once to bed, and gave her fifteen minims of aromatic spirits of ammonia every half hour. She dipped her hand in a strong solution of carbonate of soda, but this only increased the pain; poultices, however, gave immediate relief. The ammonia, too, seemed to do much good; for after two doses the headache abated, the rash began to decline, and she felt much better, although the local pain remained. She scarcely closed her eyes all night, and in the morning I found the arm much swollen as far as the axilla—where she now complained of most pain, although I could not detect that the glands there were increased in size. The lymphatics of the forearm were enlarged and hard. Poultices were continued, the hand was kept in a sling, and an aperient mixture with ammonia given during the next day. By this time the swelling of the arm had subsided, and on the morning of the following day she was sufficiently well to resume her ordinary duties.

Three days afterwards, she was again stung—this time at the back of the neck. In a very few minutes she felt so depressed, weak, and faint, that she had to be supported upstairs to bed. In half an hour her face was of a dusky, red colour, and swollen, and her body covered with an eruption, and she suffered from violent headache. I gave her a glass of brandy and hot water, and soon she felt much better. I saw her again in four hours. She then complained of urgent thirst, and was very restless—felt inclined to, but could not, sleep. Her throat felt hot and painful; and on examination, I found her tonsils red and swollen. Her pulse was quick and full. I ordered the neck to be bathed frequently and her throat to be gargled with hot water, and barley-water to be given to drink. I again saw her about five o'clock in the morning. Her throat-symptoms were somewhat relieved, but she was still very restless, and the eruption which remained was of a dusky hue, very like the rash of measles. There was well-marked coryza. In the course of the day she went home; and I heard from her frequently. The eruption lasted for three days and then began to fade; and now—six days from the date of the sting—she reports herself well, but weak.

On August 25th, my page and housemaid were both stung in the hand. The page had a swollen hand and arm, and much local pain for

about twenty-four hours. He found relief from the application of vinegar. The housemaid did not suffer for more than ten minutes, and felt benefit from the application of damp washing-soda.

On August 26th, my nurse was stung on the right upper eyelid, and felt immediately much depression, local pain, and severe headache. A little brandy and warm water and the local application of laudanum soon gave relief, but the eyelid remained swollen for two days.

I also visited about this time three patients (females) suffering with swollen arms and hands from wasp-stings. The swelling remained in each case about a day. In one, relief was obtained from ammonia liniment; in another, from vinegar; and in the last, from the application of a damp blue-bag, such as is used by washerwomen.

I have either heard it stated, or have read that, the poisonous matter of the wasp-sting has an acid reaction. This I doubt. It may be slightly alkaline, but I think probably neutral. The latter would account for many opposite and different substances giving relief. Many things have been recommended as local applications; for instance, compound camphor liniment, soap liniment, eau-de-Cologne, brandy, whiskey—and, in fact, all the spirits in common use—chalk, vinegar, spirits of sal-volatile, carbonate of soda, spirits of hartshorn, ice, honey, sugar and soap, ipecacuanha, poultices, etc. In this neighbourhood, the old women pin their faith on washing-soda or damp blue-bags.

I would suggest that the treatment be as follows. A careful examination of the wound should be made with a good pocket-lens, and any remnant of the sting removed with a pair of fine-pointed forceps. Laudanum should be applied by means of a cotton-wool swab for at least ten minutes, followed by warm water fomentations. Internally, brandy and hot water should be given at once, and twenty minims of aromatic spirit of ammonia every half hour as long as there is depression. If the mouth or throat be stung, warm flannels should be applied to the neck, and warm inhalations with ether employed. There is sure to be spasm of the rima glottidis in these cases. In no case that I have seen yet would I have given opium internally; I doubt anything but mischief from its use in any of these cases, but I am aware it has been recommended by medical writers. If local pain be not subdued by the application of the laudanum, then I think I would try the effect of a hyoscyamus poultice or tincture of belladonna sprinkled over a warm damp flannel, and applied to the wound.

## CLINICAL MEMORANDA.

### A CASE OF SPORADIC CHOLERA: EXTREME COLLAPSE: RECOVERY UNDER ELIMINATIVE TREATMENT.

I was sent for to a blacksmith of this town about 8 A.M. on August 29th. He had gone to bed well, and awoke about 3 A.M. with diarrhoea and vomiting. He became rapidly worse; and, when I saw him, he was suffering horribly from cramp all over the body, especially the hands, arms, and bowels. The evacuations from the stomach and bowels were like water with a sediment of rice. The pulse was small and thready; his complexion, naturally fair, was now of a dusky hue; his breathing was short, but not hurried; and he complained of constriction of his chest, "as if it were tied down." At 10 A.M., he was altogether worse; his pulse was not perceptible at the wrist; the surface of the body was cold, especially the extremities; the cramps were very severe. The purging and vomiting continued. At 11.30 A.M., the complexion was bluish; the surface quite dead. No pulse could be felt. Vomiting and purging occurred quite as often; the cramps were less severe. He was in a state of general apathy. Altogether the case seemed quite hopeless, and the patient moribund. At 4 P.M., slight reaction had set in. The general appearance was much the same, but the pulse could be felt. The cramps were only occasional and slight. Vomiting had ceased more than an hour. The bowels were not purged; the evacuations were the same as before. The improvement continued, and on the morning of the 30th the skin had resumed its normal fulness. He had passed some urine, for the first time since the commencement of the attack, early this morning; and the bowels had acted twice in the night; the motions were of a delicate pale yellow, and they continued so for more than a week. There was no check in his progress to complete recovery.

I attended only many cases in Manchester, during the epidemic of cholera in 1865, with milder symptoms, which got pressed fatal under the treatment then pursued. I well remember at the time thinking that we did more harm than good. I have been in the habit for many years of treating diarrhoea and English cholera withatives, such as rhubarb and magnesia with ginger and aromatic spirits of am-

monia, with an occasional dose of grey powder, and always with benefit; and, though I was thoroughly dissatisfied with the astringent method of treating cholera in 1849, yet I doubt if I should have treated this case on the principle of eliminating a poison—in fact, assisting Nature to effect a cure—if I had not read Dr. George Johnson's papers upon the subject. The prostration is so great, and apparently increasing with the drain from the system by the purging and vomiting, that we naturally strive to arrest the flux by astringents, and support the strength and restore the vital energy by stimulants. But his explanation of the cause of the collapse, by the impeded circulation through the lungs, quite convinced me. If the poison could cause such spasm of the minute arteries of the lungs, it would also cause the severe muscular cramps; while the purging and vomiting are merely an effort of Nature to get rid of the poison. So I determined, if I ever had to treat cases of Asiatic cholera, to carry out the eliminating principle of treatment; and in this case the only medicine I gave was a mixture of rhubarb and magnesia, etc., every two hours. I also used a strong turpentine fomentation over the chest and bowels, frequently repeated, and continued until the reaction had been established. I used the turpentine fomentation in consequence of the great relief that follows its application in severe cases of cramp of the stomach, and so trusted to its assisting to relieve the constricted arterioles of the lungs. The patient said: "The fomentation has saved my life; I felt as if a weight was lifted off my chest." Of course every care has been taken to prevent the disease from spreading.

I trust that the account of this case will interest the members of our profession, and induce those who may have the opportunity to try the eliminating plan of treatment. It will be seen that the discharges continued until reaction was completely established.

Kington, Hereford.

GUSTAVUS FOOTE, M.R.C.S., etc.

### EFFECTS OF BROMIDE OF POTASSIUM.

IN reference to the question proposed by a correspondent in the last week's JOURNAL, regarding the possibly ill effects that may arise from the protracted use of the bromide of potassium, I furnish the subjoined account of a case that may shed some little light upon the subject.

On June 6th of this year, Mrs. H., aged 52, consulted me for epileptic attacks occurring once or twice a week, from which she had suffered for many months. These I could not attach to any distinct local mischief, so, at once and solely, I prescribed half-drachm doses of the bromide of potassium, to be taken night and morning. The patient returned to me on the 26th of the same month. She said she felt very well, had slept better since taking the medicine, and been free from any seizure. I told her to go on with the medicine for two or three weeks longer. She came to me again on July 25th. There had been no more epilepsy, but she exhibited an unwonted aspect and deportment. She had a sad and sunken expression of countenance, an unsteadiness of gait, a general atony—a sort of ataxia—of the whole muscular system, as if a general shaking palsy were imminent. I could not resist the conclusion that before me were the toxic effects of the bromide, which she had been taking for more than six weeks. I told the patient that she would soon be relieved, and that I would change her medicine. In fact, I prescribed a simple stomachic, rather as a placebo than for any effect other than negative; telling her to take it for two or three weeks, and then to see me again. She returned to me on the 28th August, stating that she began to improve very shortly after the last consultation, and that she was now (as she looked) quite well.

Manchester, September 16th, 1871.

DANIEL NORLE, M.D.

### EFFECTS OF BROMIDE OF POTASSIUM.

IN reference to the note under the above heading, I beg to say that I have used the bromide of potassium for some years past very largely in the treatment of insanity; and although, in occasional instances, temporary depression, loss of weight, and slight furunculoid eruptions have followed its use, yet its general effects have been most satisfactory, and untoward symptoms have manifested themselves with extreme rarity. In two cases, however—the one of mania, the other of acute melancholia—crude doses, given three times a day, produced within a week extreme depression, rapid wasting, impairment of muscular power, dilatation of pupils, hesitation of speech, and great taciturnity, together with loss of mental power, amounting almost to "paralysis of thought"—a condition presenting the strongest resemblance to that which accompanies brain-exhaustion by whatever causes produced. In both these cases, suspension of the bromide was rapidly followed by the disappearance of its ill effects. Dr. Bazire makes the following remarks with reference to this remedy:—"Diminished sensibility, followed by complete anesthesia of the soft palate, uvula, and upper part of the

pharynx, is the first symptom that the patient is getting under the influence of the drug. The sexual organs are amongst the first to be influenced, for there is soon produced failure of sexual vigour, and, after a time, marked diminution of the sexual appetite itself. Another frequent, if not constant, result of the prolonged administration of the bromide is an eruption of small boils in successive crops, chiefly on the face and trunk, and accompanied with troublesome itching." Dr. Bazire, whose death was so great a loss to the profession, also gives an exhaustive account of the action of the bromide, as a note to the lecture on epilepsy in his translation of Trousseau's first volume.

Dr. Ringer observes, in his excellent work on *Therapeutics*: "It also produces bodily and mental depression, and the patients become low-spirited, subject to gloomy ideas, are soon fatigued and unfitted for work. On the suspension of the medicine, all these symptoms and appearances soon subside."

FREDERICK NEEDHAM, M.D., Medical Superintendent.

The Asylum, Bootham, York, September 16th, 1871.

#### EFFECTS OF BROMIDE OF POTASSIUM.

I had a young lady under my care for nine months, suffering from epilepsy, for which I prescribed the bromide of potassium. She commenced with fifteen grains, and continued until she was taking forty-five grains, three times daily. She suffered, as the result of these large doses, from intense depression of spirits, great bodily weakness, and an eruption very much resembling ecthyma. She was very drowsy at times, and had a most offensive fetid odour arising from her breath, which was so bad that no one could stay in the room with her. Her memory was greatly impaired, and on one or two occasions her mind seemed a perfect blank. All these symptoms subsided on discontinuing the bromide, but, at the same time, the frequency of her epileptic seizures increased.

Congresbury, Bristol.

WILTON PROVIS, L.R.C.P.

#### EFFECTS OF BROMIDE OF POTASSIUM.

IN several cases, when administered in doses of several scruples in the course of the day, I have seen bromide of potassium produce symptoms of gastric disturbance, as indicated by pain after food, vomiting, and pain on pressure in the epigastrium. It also causes a great increase in the quantity of urine passed; but what I chiefly wish to refer to in this note is the case of a gentleman, aged 65 years, who has been taking bromide of ammonium for the last nineteen months. He had had epileptic fits, before I saw him, four times, and, as a curious coincidence, with an interval of exactly two months between each two attacks. He was then prescribed half a drachm of the bromide every night, which increased the interval to four months. I then increased the dose to forty grains, and ultimately to a drachm per day. He now began to show signs of great nervous disturbance, together with gastric irritation. He suffered from severe pain in the muscles of the leg and back of the thigh. There was great depression of spirits, almost amounting to melancholy. He was totally incapable of attending to any business. He slept badly. There was complete anorexia. There was also pain on pressure just above the umbilicus, with frequent vomiting, often hæmatemesis and melæna. He complained of much pain after food. The bowels were rather constipated. The pulse was 80, compressible. He had another attack of convulsions, and it was now decided to reduce the dose to half a drachm daily, when gradually the bad symptoms disappeared. He is still taking the same dose with the most satisfactory result, seeing that he has not had a recurrence of the fits since the resumption of the old dose—now fourteen months ago. He had no delusions. I did not observe the state of the pupils. There were drowsiness and slight failure of memory.

R. W. FOSS, M.D., Stockton-on-Tees.

BEQUESTS, DONATIONS, ETC.—Mr. Joseph Jackson, of Northumberland Park, Tottenham, has bequeathed £10,000 to establish in Shore-ditch a soup kitchen and cottage infirmary, to make up four beds, with paid housekeeper and surgeon.—Mr. M. B. Mullins, of Fitzwilliam Square, Dublin (in addition to the legacies to medical charities previously mentioned), bequeathed £500 to the Coombe Lying-in Hospital.—"R. M. H." has given £300 to the Halifax New Infirmary.—Mr. Samuel Morley, M.P., has contributed £100 towards Mrs. Gladstone's Convalescent Home.—The West Kent General Hospital, Maidstone, has received £100 under the will of Mr. T. R. Cutbush.—Messrs. Iliff and Mounsey's workmen have subscribed £23:7:8, and the North-Eastern Marine Engine Works' workmen £25:12:5, to the Sunderland General Infirmary.—Mr. Edward Wigan, of Hibernia Chambers, London Bridge, bequeathed £1000 to the London Fever Hospital, and £500 each to the London Hospital, King's College Hospital, and Charing Cross Hospital.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### MIDDLESEX HOSPITAL.

HYDATID PREGNANCY ATTENDED BY PROFUSE HÆMORRHAGE.

(Under the care of Dr. EDIS.)

FOR the report of this case we are indebted to Mr. J. W. LANGMORE, M.B., Resident Obstetric Assistant to the Hospital.

C. T., aged 17, single, a tailoress, was brought to the hospital late on the night of August 12th, in a state of extreme syncope, and with her clothes saturated with blood. She was said to be generally a healthy girl, with fresh colour; but her face was now blanched, and the expression anxious; pulse rapid, small, and jerking. On examination, the uterus was found to reach one and a half inches above the umbilicus; the breasts were full, the areolæ very dark; thin milk could be expressed from the left nipple. No fetal movements could be felt, nor could the heart be heard. The placental bruit was weak and indistinct; it was best heard low down on the left side. The vagina was narrow, full of clots; the os uteri was high up, soft and dilatable; no cervix could be found. No presentation could be felt. There was a general soft, doughy feeling over the whole of the lower segment of the uterus; on passing the tip of the finger through the os, only clots were met with. Only an imperfect history could then be got from the mother. Many of the following details—e.g., the former flooding—were only obtained from the girl afterwards. The catamenia had been absent eight months. The patient had been taking pills and medicine to bring them on—i.e., to procure abortion; she had had some pennyroyal. On the 4th instant, she had a sharp attack of hæmorrhage from the vagina, while in the street. It came on suddenly without pain—one gush of blood. The patient was assisted home, close by, and the bleeding did not recur. This evening she went for a long drive in a cart, and had just returned, when she had a second, and much more severe, flooding. This also came on without the slightest pain or warning. She was at once brought to the hospital. As there was no recurrence of the hæmorrhage, the patient was suffering much from shock, and the nature of the case was not quite clear, it seemed better to allow her to rally a little, if possible, and not to attempt any operative interference unless it were absolutely necessary. She was, therefore, put to bed; the clots were removed from the vagina; cold was applied over the pubes and between the thighs, and a careful watch kept. Half an ounce of brandy every two hours was ordered.

Next day the patient was much better; had slept well. There were no pains; no hæmorrhage; the pulse was 76, soft and rather jerking. Examination of the abdomen and the vagina gave the same results. In the absence of Dr. Hall Davis from town, Dr. A. W. Edis was sent for. He confirmed the diagnosis of placenta prævia; and decided to induce labour at once. Barnes's dilators were introduced one after another, until the os was large enough to admit three fingers. A soft granular mass could be felt inside—apparently the placenta. Dr. Edis separated its attachment all round the os, first with the finger, then more widely with a thick sound; scarcely any bleeding occurred; still no membranes could be felt, and no presentation. As the pains were very weak and irregular, ergot was given, and produced a few efforts, but did not alter matters. Dr. Edis then explored the cavity of the uterus with a blunt hook, but met with nothing; on withdrawing it, however, two or three small white vesicular bodies were found adhering. The nature of the case was now clear. The ergot was repeated, and, by means of one blade of the small forceps, the uterus was emptied of a mass of hydatids, which nearly filled an ordinary hand-basin. Brandy had to be administered freely during the operations; the patient, however, bore them better than might have been expected.

She made a steady and comparatively rapid recovery. The breasts gave some trouble, the secretion of milk being very abundant and persistent. She was discharged quite convalescent on Sept. 12th.

#### ABERDEEN ROYAL INFIRMARY.

CASE OF DIRECT MITRAL OR PRESYSTOLIC MURMUR.

Under the care of Dr. BEVERIDGE.

(Communicated by Dr. JAMES F. GOODHART.)

THE subjoined case would always, from its own intrinsic interest, be well worthy of perusal; but a record of it is especially valuable at the

present time, because a most valuable paper, lately published by Dr. Fagge (*Guy's Hospital Reports*, vol. xvi, series iii, 1870-71, "On the Murmurs attendant upon Mitral Contraction"), has given a *résumé* of the various opinions held by different authorities in such cases, and the whole subject, it is to be presumed, is, therefore, still fresh with interest in the memory of many. For this reason, Dr. Beveridge has kindly allowed me to publish my notes of the case, and has further supplemented them with his own and those of Dr. Rodger, the pathologist at the Infirmary, who conducted the *post mortem* examination.

Jessie Anne H., a servant, aged 17, was admitted December 27th, 1870, complaining of weakness and partial loss of power over the limbs. Her body was much emaciated, and her aspect was dull and stupid; she was also languid, and disinclined to answer questions. She said that she was left an orphan at an early age, and had been subjected to hard treatment and poor living. She could give no history of rheumatism in her family, and she herself did not appear to have ever suffered from anything of the kind. She complained chiefly of severe headache, with partial anæsthesia of the left arm and thigh. The muscular power on that side was very slightly impaired. The cornea of the left eye was conical, and partially opaque; in other respects there was nothing especially noticeable on examination of the head or abdomen. Percussion over the chest was natural. The respiratory sounds were weak on both sides, but no abnormal sounds could be heard. The heart's action was quick, the stroke well marked and very apparent to the eye. There was a distinct presystolic bruit, absolutely limited to the apex; while over the lower part of the sternum, near its left margin, was a loud systolic bruit, different in character and time from that audible at the apex, being louder and harsher to the ear, and accompanying instead of preceding the heart's stroke. Pulse 90, weak; appetite impaired; urine scanty and high-coloured, but otherwise natural.

On examination, a few days after admission, I found very slight anæsthesia, if any, and no marked hemiplegia. She was very drowsy and stupid, and it was very difficult to obtain any account of her own feelings. The teeth were irregular, but there was no syphilitic notch. The lips were rather blue, and the finger-nails also. She looked rather cyanotic. There was no splenic enlargement; nor any marked increase of the precordial dulness. The impulse was diffused, and there was a strong thrill communicated to the chest-wall. The heart was beating about ninety per minute. On auscultation, there was a characteristic churning, strictly presystolic, *bruit* at the apex, which disappeared towards the axilla, but was plain towards the ensiform cartilage. At the base, there was a peculiarly sharp and high-pitched second sound, which was reduplicated, the second part being nearly as loud as the first. On passing down from the aortic valves to the apex a crumpling sound was heard, which at first I mistook for moist *râles* in the bronchial tubes. This almost disappeared now and again; and as the stethoscope passed down to the apex it apparently merged into the presystolic sound.

Under the use of bromide of potassium, the head-symptoms disappeared, but the general debility increased. On the 7th of January, a loud friction-sound was audible over the heart, which lasted four days and then disappeared. She gradually sank, the *bruit* becoming less audible, and died on January 18th.

*Inspection Two Days after Death.*—The præcordial space was enlarged, the lump but slightly covering the heart. The pericardium contained a little serum, but was healthy. The heart weighed eleven and a half ounces; its right side was dilated slightly, and the free edge of the tricuspid valve was rounded and thick as if from old endocarditis. The valvular orifice only admitted two fingers. The pulmonary artery was healthy. The left auricle was dilated without much hypertrophy. It was three parts full of *ante mortem* clot, which began in front behind the auricular appendix (which was empty), and extended backwards and outwards to the posterior angle. The inner and back part was free, and formed a small channel from the pulmonary veins to the mitral orifice. On section of the clot, the anterior part was triangular, with its apex forwards, firmly united to the auricular wall. It was laminated and somewhat bony, the centre being yellowish, with a few points or centres of fatty degeneration. The outer layers (next the auricular wall) were calcareous; and Dr. Rodger notes that the endocardium was thickened from deposit in its substance. Behind this firm part, on its free surface, or part facing towards the cavity of the auricle, and joining on to it, was a much larger mass of soft papillated decolorising clot, and from this quite recent clot extended into the pulmonary veins. The valve itself presented two narrow openings, which scarcely admitted the point of the little finger, and which were formed by contraction and growing together of its flaps. The aortic opening was normal. The lungs were extensively solidified and splenised in the lower lobes from prolonged congestion, the right being the most diseased. The liver was small but healthy. The kidneys were anæmic, with slight

parenchymatous deposit. The spleen was small (four ounces and a half) and pulpy. The uterus and ovaries were healthy. The brain weighed forty-five ounces. Much tubercular deposit was found between the cerebral lobes on each side of the falx cerebri, also on the upper surface of the corpus callosum, with a few points of extravasated blood. At the base over the pons, there was also extravasated blood, in punctiform spots, and the membranes covering the space in front were thickened and opaque. Tubercular formation also existed along the fissure of Sylvius.

**REMARKS.**—The chief features to be noted in the case are, that during life the patient suffered from a slight, partial, and transient paralysis; that she had a somewhat cyanotic appearance; and that a presystolic *bruit* at the apex, and a double second sound at the base, were heard, as well as a systolic *bruit* towards the ensiform cartilage; while after death such conditions existed as to completely verify the diagnosis which had been made of "mitral contraction complicated with a tricuspid *bruit* and tubercular meningitis". But in attempting more closely to reconcile the observations recorded before death with the facts or conditions which existed at the necropsy, we meet with some difficulties. First, as to the origin of the presystolic murmur: the double second sound was heard most distinctly, and was succeeded by, or rather gave place further down towards the apex to, a crumpling noise; and this again seemed to graduate by inappreciable degrees into a well marked presystolic sound;—all facts tending, if the contraction of the auricle be the cause of the murmur, to prove the correctness of Dr. Fagge's theory, that the additional sounds are really produced by the early and prolonged auricular systole. On the other hand, against such evidence it may be reasonably objected that such a state of parts existed, viz., nearly complete filling up of the auricle, as would, one would have thought, have precluded the possibility of any contraction taking place at all; not only so, but along with the physical obstruction to contraction, there of necessity existed a loss of one great stimulus to contraction—viz., the periodical distension. In answer to this, however, it may be said that a heart, if removed from the body, would still for a time continue to contract in virtue of its own inherent rhythmical nutrition (as it has been called), and that this would probably enable it to supply the deficiency, or rather to accommodate itself to altered conditions and a less full distension. But still it is hardly conceivable that the heart could continue its action with one of its cavities completely paralysed; and, therefore, it is fair to assume that in this case a contraction of some sort, or perhaps, more correctly, an attempt at contraction, must have taken place. Probably the muscular fibre acted slightly, and in so doing kept up, in some measure, the normal rhythm. That scarcely any actual lessening of the cavity occurred is evidenced by the fact that the obstruction to be overcome was extreme, while at the same time the auricle was hardly, if at all, hypertrophied; whereas if any attempt had been made to overcome the obstruction, its muscular wall would by so much have increased in thickness; and even if at this time, tired out, it had ceased to act, the evidence of former effort would still have remained.

If, then, the auricular contraction causes the *bruit*, the mere attempt at contraction must have caused it in this case. But the sound was, it has been said, remarkably loud, whereas if, as I suppose, hardly any contraction occurred, there should have been but a barely audible *bruit*. It must be admitted, I think, that the muscular tension alone would not in this instance overcome the difficulty; but a sufficient explanation on the same theory may probably be found in the thickening of the auricular wall by very old organised blood-clot, and in its very intimate connexion with the lining membrane of the auricle. This lymph might be equivalent to the extra muscle of a hypertrophied auricle as far as vibration and tension only were concerned, while in the matter of contraction it would be of no use whatever—nay, more, it would be a positive impediment to the action of the muscle. In support of this view, the "crumpling" heard midway between the base and apex of the heart, which, if Dr. Fagge's theory be correct, must have come from the auricle, was just such a sound as might have been produced by the horny and laminated clot, with its calcareous particles.

We have next, without entering fully into the question as to whether or not the conditions under which the heart acts are such as to imply the necessary performance of a certain amount of work in a certain time, or, as an alternative, the failure of its action—a physiological necessity by no means to be demonstrated from the problems of disease—to inquire whether, if no contraction of the auricle took place forcible enough to be productive of good in maintaining the onward blood-flow, the round of the circulation could be carried on. The instance under consideration would appear to show that in such a case the circulation could be kept up, probably through the combined action of various accommodating circumstances—one being the partial failure of the heart's action, with the production thereby of engorgement of the viscera, having much the same effect upon the heart as would a general bleeding.

The amount of blood flowing towards the centre of the circulation being thus lessened by its detention in such organs as the liver, lung, and spleen, a less powerful contraction is brought about; and, inasmuch as there is already an excess of blood in the lungs and pulmonary veins, the diminished contractile force is still sufficient in passing the blood on towards the ventricle. As matters become gradually worse, both the amount of blood to be sent onwards and the muscular force decrease—the one in volume, the other in power—and then clotting takes place in the auricular cavity. By this means the closure of it during its systole is prevented, and the blood can be constantly trickling from the pulmonary veins through the left auricle into the ventricle. Some such process as this must have gone on in our patient to have enabled her to live on as long as she evidently had done. These are important points, because they seem to clear up a difficulty noticed by Dr. Hyde Salter, that if the auricular systole be prolonged it is hard to see how the auricle can have time to fill from the veins. But the probability is that in this case, and therefore in others like it, the auricle *could not* close, and, so no matter how soon it began to contract, the cavity that remained would still be able to receive blood. Given a heart in a state of health, and allow that the auricle is closed immediately on the cessation of the second sound, then no doubt the difficulty would be a real one; but it ceases to be so if any evidence can be adduced to show that in such cases the auricular cavity is not obliterated during its systole, and that it remains patent during the whole round of the heart's action; and if it does so remain patent, the truth of this remark is enforced, "that mitral contraction, when present in any marked degree, must necessarily alter the conditions under which the auricle works, much more than has hitherto been supposed". (Dr. Fagge, *op. cit.*, p. 338.)

Another point in the case is, that the patient was admitted with a transient hemiplegia, which, taken with the heart-disease, obviously pointed to an embolus as its cause. Tubercular meningitis, however, was present; and, no clot being found in the cerebral vessels, it must be held that the tubercle was a sufficient and probable explanation of the paralysis: still it is interesting to observe that in other cases, cerebral symptoms have been found for which after death no cause could be discovered. That embolism should be a frequent occurrence in this class of cases is a thing to be expected, when it is remembered that a condition closely simulating that of a fusiform aneurism exists, and the blood flows by somewhat narrow orifices into a dilated cavity, at the other extremity of which it makes its exit; also by a channel of smaller calibre than the cavity itself.

It is also to be noted that a pericardial friction-sound was heard a few days before death, but that the membrane was found to be healthy, with the exception of a little serum being contained in its cavity; and that the tricuspid valve apparently had undergone a similar change to the mitral, though in a less degree, no history of rheumatism or acute heart-disease being given to account for it in either.

Dr. Beveridge agrees with Dr. Fagge in thinking that the presystolic *bruit* is far from being uncommon, and that the mistake is frequently made, when two sounds are audible at the apex, to set them down without further examination as the first and second sounds of the heart, whereas they often are a presystolic *bruit* and the first sound. He also thinks that the presystolic sound is probably caused by the blood flowing through the narrow and roughened orifice. If, however, the opening—no matter how small—be smooth in its margins and surfaces, and the ventricle fill slowly, then there may be no sound, or none sufficiently loud to be audible; if the orifice be rough and the heart act quickly, then the sound is usually there. The observation made by Dr. Fagge, that the presystolic sound is much intensified by any thing that increases the rapidity of the heart's action, which is quite correct, also points to the same conclusion.

#### NEWCASTLE GENERAL INFIRMARY.

##### A CASE OF OVARIOTOMY.

(Under the care of Mr. RUSSELL.)

J. B., unmarried, aged 23, the subject of ovarian dropsy for a period of eighteen months, was tapped in May 1870, and twenty-one pints of characteristic fluid evacuated. On March 3rd, 1871, paracentesis was again performed, and eleven pints of fluid drawn off. Mr. Russell now determined to perform ovariectomy, but wished to do so when the cyst was distended to about half the size it was at the last tapping. Accordingly, on the 28th of April, the patient having for some few days been kept upon a fluid diet, and the bowels having been efficiently relieved by means of gentle aperients, the tumour was exposed by an incision barely four inches in length. The cyst, a very tough and thickened one, was punctured with a trocar, and, there being no adhesions whatever, was readily drawn through the wound, together with two others, unevacuated, one of the size of an orange, the other twice as large.

The pedicle, broad and short, was secured by Mr. Spencer Wells's straight-clamp, and the edges of the wound were retained in contact by means of five silver sutures, made to pass through the peritoneum and abdominal parietes an inch on each side of the incision. The wound was dressed with lint, soaked in equal parts of carbolic acid and glycerine. A pillow made of lattice-lint, and stuffed with teased oakum, was firmly secured over the abdomen with a broad four-tailed flannel bandage: and, with the exception of a linseed-meal poultice occasionally taking the place of the pillow at night, this method of dressing was pursued for seven days, by which time the wound was entirely healed. The sutures were removed on the third, and the clamp on the fourth day. With the exception of ice to suck in small quantities, the patient was fed altogether by the rectum, receiving six ounces of beef-tea, with from one to three table spoonfuls of brandy, every four hours, till the seventh day, when solid food was retained, and the injections were gradually discontinued. The bowels acted spontaneously fourteen days after the operation, and the patient left her bed on the fifteenth day. A laxative was administered on the seventeenth day. During the after part of the day of operation, the patient complained of very acute abdominal pain, for which opium was administered freely by the rectum in the form of tincture, and suppository combined with belladonna, but without alleviation. Hypodermic injections of morphia quickly gave relief, and they were repeated twice or thrice daily for ten days. The patient left the infirmary cured on June 1st, and continues quite well, menstruating regularly.

#### EAST SUFFOLK HOSPITAL.

##### HALFPENNY IMPACTED IN THE LARYNX.

FOR the report of this case we are indebted to Mr. G. S. Elliston, House-Surgeon.

A few days ago, a man was brought into the hospital, having swallowed a halfpenny. It appears that, while playing with his children on the floor, he put the halfpenny into his mouth, and jerked his head back to prevent them from getting it, when it slipped down. At first there were pain in the throat and a difficulty in articulating. A probang was passed into the stomach, after which he vomited, but no halfpenny came up. The laryngoscope was then used; and with some difficulty, owing to the irritable state of the throat, a dark foreign body could be seen covered with mucus in the larynx, but quite out of reach. The use of the laryngoscope caused great retching, followed by dyspnoea and severe fits of coughing, during which the patient was forced with his head downwards on to his hands and knees, but without success. After half an hour the breathing became more difficult, and it appeared as if the coin were settling down more into the windpipe. He was directed to drink half a pint of warm water, and to slowly inflate his lungs. The fauces were then tickled, which brought on a violent fit of vomiting and retching, and the patient was again forced on his hands and knees with his head well down. After a prolonged fit of coughing, during which the man became livid in the face, the halfpenny dropped out, having been in the larynx nearly two hours.

## REPORTS AND ANALYSES

### MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### POROPLASTIC SPLINTS.

MR. JOHN COCKING, of Penzance, has submitted to us a new material for splints. It is truly described as elastic, light, porous, flexible, plastic, and economical. It is made in all required strengths and sizes, and consists of a felted substance in sheets; it is plastic when softened by heat, and becomes rigid when cold, and can be re-softened repeatedly without injury. It is rapidly and easily manipulated, the most difficult splint requiring but a few minutes to mould and finish; and it is very well adapted for metal attachments, and is thus a very valuable material for interrupted splints. There is no glue used in its application, and the gums with which it is stiffened are quite harmless. "To country and colonial practitioners, invaluable"—in the words of Mr. Jonathan Hutchinson, the Senior Surgeon to the London Hospital, where it was introduced by him with great success, and has been used for some time. By attending to very simple directions for use, the most perfect splint yet known may be made. A "hospital quality" is supplied by Messrs. Maw and others at 4s. per lb., in substances of about one-eighth of an inch, three-sixteenths of an inch, five-sixteenths

of an inch, and in sheets measuring about four feet by three feet; and an "ordinary quality" at 6s. 6d. per lb. We earnestly recommend it to our army surgeons, believing that for field-hospital purposes it will supersede all others.

## BRITISH MEDICAL JOURNAL.

SATURDAY, SEPTEMBER 23RD, 1871.

### MINERVA MEDICA.

A VERY voluminous discussion has occupied recently the pages of the *Echo*, on the subject of midwives. The prevalent delusions on both sides have been freely aired; and, except that free discussion is never altogether without good, we must express disappointment that the heart of the matter has been but little touched. It is not the fact that the medical profession either have felt or now feel any reluctance to see women enter upon this useful department of activity. Women have been very slow to do so, and seem to meet with very little encouragement from the ladies—much less than one would expect. This is possibly due to the fact that they have never gone unitedly and intelligently to work; and very few women of education or respectable social position have been inclined to adopt the midwife's calling. It is, in truth, very trying; on an average, poorly remunerated, and only to be carried on satisfactorily either by laborious women who smile at hardships, or by celibates. Of course, women who marry carry on the occupation under peculiar disadvantages, as compared with men, setting aside the original difference in capacity for exposure to all weathers, untimely night-expeditions, and long hours of unexpected physical exertion. The obstetrical hospitals have always been open to women; and our best obstetric physicians, whether in London, Dublin, or elsewhere, have always been willing to teach them. What is really wanting to obtain for able midwives a status superior to that of the ordinary Sarah Gamp is the preliminary education of a lady, and willingness to submit to a satisfactory technical examination. If there are any number of them who believe themselves able, and who are willing, to fulfil these essential preliminaries, they have only to apply to the Obstetrical Society, and we are satisfied that that body will supply them with a board of examiners sufficiently impartial and eminent to give weight to their certificates.

One gentleman, we observe, states that the Female Medical College has met with unrelenting disfavour. Many well-wishers of women have, in fact, not shown it any favour; and many sensible women desiring a complete medical education, such as Miss Garrett and the *septem contra Edinam*, have practically testified their opinion by keeping away from it. The main ground of disfavour is, we suppose, that it is not a medical college in the proper sense of the term. A medical college must fulfil certain conditions which all male medical colleges observe, and on which depends their recognition by the examining bodies, and their value as educational bodies. They must give a certain defined number of lectures on a certain complete series of subjects, each lecturer taking his own subject, and the lecturers being persons approved by the Colleges as of sufficient standing and ability. They must provide adequate means of instruction by preparations, museums of normal and pathological anatomy, &c. They must supply adequate means of clinical instruction. The ladies have not yet even attempted the no doubt difficult but certainly not impossible enterprise of supplying themselves with anything resembling a medical college and clinical hospital. In London alone, the male part of the community have founded for themselves twelve. If the ladies who desire medical education were at all numerous or much in earnest, they could not have much difficulty in founding one. They prefer to *latter en brache* the possessions of the male, and to claim a seat by the side of the male students in the amphitheatre of surgery, in the deadhouse and the dissecting-room. The shortest route is not always that which is travelled most quickly; and,

if the citadel of medicine is to be conquered by the fair aspirants, we doubt it must be taken in flank. The day that a Portia presents herself, pointing to an educated class of female students passing soberly through a complete and well ordered curriculum of medical study, such as is prescribed by the General Council of Medical Education and Registration, the battle will be more than half won, before medical opinion, so far as the conquest of the rights of the feminine sex is concerned.

Some very grave doubts remain; and, sceptics as we are, we profess the most sincere incredulity that there are, or ever will be, any number of the sex able or willing to profit by the conquest. The obvious sexual limitation of the activity of female doctors excludes them from competing with men for all the ordinary and primary means of livelihood which are the support of the young man on entering the profession. It shuts them out from the army, the navy, the Poor-law Medical Service; from resident hospital appointments (except for women and children); from the commercial marine; from surgeoncies to mines or factories; in fact, from the great bulk of the avenues by which the average practitioner enters practice. Even in ordinary, unshackled civil practice, they are, by the necessities of the case, confined to special departments of practice. Even here they will labour under great difficulties, from the peculiarities of the female constitution and the incidents of marriage. But here there is a plausible ground of preference in the minds of some. It does not seem to us that the few who desire to enter upon this field of activity, are bound to stop by reason of the argument (urged by Dr. Chambers, in his sequel to the Harveian Oration), that the profits which they may gain are, in fact, subtractions from the gains which men in marrying lay at the feet of the women whom they marry. Not all men or women marry. The individual who wishes to work is not to be repelled by the consideration that, in remaining idle, he or she would leave the field open to other workers. Besides, Dr. Chambers's argument would raise an equal objection to nearly all kinds of female work, whether in counting-house, shop, or telegraph-office. It is not tenable. Without a morsel of gallantry, therefore—which in such an argument is out of place—and with a deep-seated dislike for all propositions for mixed classes, or for any other arrangements which seek to sophisticate or efface the relations of the sexes, we desire, and we believe the profession at large desires, to see oppressive barriers removed from before ladies who wish to qualify for medical practice in obstetrics and diseases of women. The largest part of the work rests with themselves, and those who have their cause at heart. They must establish their own schools. It is quite evident, from the number of eminent physicians who have testified their sympathy with the past efforts of ladies, that this rests entirely with themselves. They will be readily enough admitted to obstetrical hospitals; and, if they desire the use of a clinical hospital, they must find, or found, one not preoccupied by male students; both can be done. The walls of our modern Jericho will not fall before the sound of a voice, however fluty or nicely modulate. But the gates will open to those who provide themselves with passports moderately in order, and with proper qualifications. The ladies have not yet properly occupied the field of midwifery, within the limits long since open to them. They still complain, and not without reason, that the best educated of them are undistinguishable from the unqualified pretenders. Primitive disorganisation still reigns among them. What have they done to remedy it? Let them study the history of the corporation of Surgeons—at first, barber-surgeons; of the Society of Apothecaries—at first traders. They will see that, in this country, great institutions have a vital growth, and are not turned out of a mould. They grow up by the natural process of differentiation: the efforts of the well-educated and right-minded classes to differentiate themselves, and to establish tests. The thing first, and the test afterwards. We have had amongst us for centuries midwives, bad, good, and indifferent. Let the good separate themselves; they will find abundant help and countenance from the authorities of the medical profession.

## THE LESSONS OF THE WAR.

STROMEYER, the surgical historian of four campaigns, and one of the most able and sympathetic of surgical writers, has published a translation, with copious commentary, of Mac Cormac's *Recollections of the Work of an Ambulance Surgeon in the Franco-German War*, which appeared last year in our columns.\* Stromeier's clinical experience of the surgery of war dates back to 1848, when the revolution of the Grand Duchy of Baden filled his clinical wards with gunshot-wounds. Here he could study them with the greatest ease, and prepared himself for a larger field of observation during the two campaigns in Schleswig-Holstein in 1849 and 1850. In 1850, his first observations on gunshot-wounds appeared in an article on Gunshot Fractures in his *Handbook of Surgery*. The first edition of his celebrated *Maxims of Military Surgery* appeared in 1855; it has since achieved a wide popularity. His report on the battle of Langensalza appeared in 1867.

Dr. Stromeier, in his fifth and final war campaign, was first ordered to join the Crown Prince and the third Army Corps; afterwards he was attached as Consulting Surgeon to the Eleventh Corps, and remained at Versailles during the entire German siege, where his duties lay in the Hospital of the Chateau. He was present at the battle of Sedan, and caused an ambulance to be erected in the little village of Floing, just outside the walls, where the fight had raged fiercely. Stromeier gives an interesting and opportune account of the prompt manner in which the General of Division detached a corps of Engineers for his services, and how speedily the requisite wooden huts which formed the ambulance were erected; and he expresses the hope that a more extended use of those wooden temporary huts, improvised with such materials as are at hand, may be made. He greatly prefers them to tents, which he says may, as a complete English ambulance was, be blown away altogether, besides having other drawbacks.

On hospital hygiene generally, Stromeier makes some very valuable observations. He lays great stress on adequate heating of the wards, and details the deplorable effects which he witnessed during the war in consequence of the want of it. With great and sudden variations of temperature not properly guarded against, Stromeier observed in Schleswig Holstein, in 1849, that tetanus, angina, erysipelas, rheumatism, pyæmia, and metastatic abscesses were very common during the cold weather, and less so if the temperature were mild, or the wards kept properly heated. Indeed, throughout his observations, he instances cases where the effects of cold, even locally applied, produced bad results; as, for instance, in a case of penetrating wound of the knee, where the prolonged use of ice to the joint induced diarrhoea and extreme depression, from which the patient completely rallied on the removal of the ice. Indeed, he looks upon cold and draughts as almost as dangerous enemies to operation cases as overcrowding. "When I first came to Versailles," he says, "the weather was already cold and stormy; and in the hospital, which was not heated, it was observed that the wounds frequently became coated with a diphtheritic surface, which was attributed to pyæmic causes; and all sorts of means were employed to combat it, including excessive ventilation and carbolic acid *ad libitum*. It did not avail, and my expression of opinion was not attended to. I urged that we had to deal with atmospheric and not miasmatic influences. But I had the opportunity before long of demonstrating the correctness of my views. A wound, granulating perfectly after a Chopart's amputation, was in a single night covered with a thick white diphtheritic layer, and during the otherwise perfect well-being of the patient. It disappeared immediately after the patient was kept warmer, and with only a simple oiled dressing applied. It was thought that it must be some defect in the carbolic acid, but the terrible warning of the month of October caused a change. Eleven operations, per-

formed on the 21st of October, died—viz., seven amputations of the thigh, one of the arm, two resections of the shoulder, and one of the elbow. After this, the excessive amount of ventilation was moderated, stoves were introduced, and the beneficial effects will be made manifest in some tables by the chief surgeon of the Chateau, which will shortly be published, and which will give a comparative account of the mortality after operations during the different periods." In these times, when ventilation is considered a panacea, it is of great importance that an authority no less eminent than Stromeier should call attention to evils which during cold weather attend the unrestricted abuse of air-currents; and if we cannot agree that draughts of cold air are *per se* as dangerous as overcrowding, we can fully admit that warmth, as well as fresh air, is absolutely essential to the safety and comfort of the wounded, and especially those operated upon.

On the subject of probing gunshot-wounds, Stromeier says this should never be done in cases of fracture of the shafts of bones which are intended to be treated conservatively; and that in operation cases the examination should be made immediately prior to the operation, during the chloroform narcosis, and not twenty-four hours previously.

In his chapter on antiseptics, Stromeier betrays a considerable amount of scepticism in the all-sufficing value of carbolic acid. He recommends the use of comparatively weak applications, and confesses to a longing on some occasions to dispossess the carbolised dressings for the simple oil and water dressings of earlier campaigns. He also reproaches the unlimited irrigation of wounds, which, he states, often causes great mischief.

Stromeier thinks that nationality has considerable influence on the progress of wounds in different persons. A difference seemed to exist, he says, between the Danes and Germans, the Danes being more irritable, but easier to heal than the Germans; while Thiersch observed that even after severe injuries the Turcos readily got well. Stromeier, in speaking of injuries of the head, alludes to an expression of doubt by Mac Cormac on Brodie's doctrine that in an open wound of the head with brain-symptoms we should interfere by operation. Stromeier considers it far better to leave such cases alone. Mac Cormac, he says, is on the right way when he recommends them not to be trephined. Professor Fischer desired to find in the battle-field itself an asylum for what he styles the "disowned child of surgery;" but Stromeier thinks that even there it has never been performed, and "that therefore it has had no opportunity of bettering its condition in the field of battle as did many an *enfant perdu* in days gone by."

"Torsion of arteries," says Stromeier, "has never been so thoroughly tried in the field as by Mac Cormac, who used it in more than one hundred capital operations with evidently good results, even for the largest arteries." Stromeier has remained faithful to the ligature.

Of secondary hæmorrhage and the results of the ligature of arteries for it in their continuity, Stromeier speaks despondingly, and endorses Mac Cormac's opinion as to the almost uniformly unfavourable results which attend such operations. He says he has witnessed twelve cases of ligature for secondary hæmorrhage, and only twice did the patient recover. "I think," he says, "we must decide to amputate oftener in cases of secondary hæmorrhage." He then gives some very interesting observations on spontaneous healing of injured arteries, and the means best adapted to procure healing of wounds of the large vessels. Some most valuable remarks are made on the subject of venous hæmorrhage or the bleeding caused by thrombus in the veins. Many pages are devoted to this subject. It is too long to give here, and we must refer our readers to the original, merely observing that many of Stromeier's deductions are of extreme practical value.

In reference to gunshot fractures of the shafts of bones, Stromeier lays down the important statement as a fact that, so far as is known to him, no patient died under conservative treatment. The great principle which he recommends in order to carry out this treatment efficiently is the principle of "no restraint"; and this principle is carried out so far as to maintain the position in which the fracture unites to be a matter of secondary consideration—union first of all; if with deformity,

\* Notizen und Erinnerungen eines Ambulanz-Chirurgen, von William Mac Cormac, Wundarzt am St. Thomas-Hospitale in London, etc. Aus dem Englischen übersetzt und mit Bemerkungen versehen von Dr. Louis Stromeier, Verfasser der Maximen der Kriegsheilkunst. Hannover: Hahn. 1871.

that must subsequently be cared for. He objects to powerful forcible extension, especially in fractures of the thigh, for which, as for the leg, he strongly recommends the position on the side, as adopted by Pott. In the first instance, the endeavour should be made by all means to save the life of the patient with fractured thigh; and after that is accomplished, to make the deformed limb, if possible, longer and straighter. The attempt to procure both at the same time often sacrifices life, while it does not guarantee absence of deformity. The following table shows how much better the results obtained by conservative treatment of fractures at Floing were than in the earlier wars.

	Deaths.	Mortality.
Schleswig-Holstein, 1848-50.....	28 .....	14 ..... 50 per cent.
Langensalza, 1866 .....	25 .....	15 ..... 60 „
Floing, 1870 .....	35 .....	8 ..... 23 „

In the leg similar results were obtained. "Thus," says Stromeyer, "I have during the last campaign lived to see what I expressed a desire for in my *Handbook of Surgery* after the first. 'Above all things it appears to me to be necessary that cases of gunshot-fracture of the thigh should not be transported to a distance, but should be carried on a stretcher to the nearest house, and the treatment carried out there, even at the risk that the wounded should fall into captivity.' In Floing this happened by accident; but such opportunities should always be taken advantage of."

The chapter on resections is most valuable. Stromeyer is in favour of primary operations; and he does not appear to be a strong adherent of subperiosteal resection, whose advantages he considers exaggerated, especially as applicable to military surgery; and he strongly disapproves of what appears to have been the practice in the German armies of allowing cases for primary resection to drift into secondary, in order that they may be performed subperiostally—a proceeding naturally difficult, if not impossible, in healthy recently injured bone.

Interesting particulars are given respecting excision of various joints, which space does not permit us to detail.

In regard to amputations, Stromeyer strongly sets forth the importance of primary operations; and mentions that at Langensalza in one place nine amputations of the thigh were performed within twelve hours of the battle of Kirchheilingen; that of these but one died.

We cannot refrain from quoting finally the hearty and sympathetic words with which Stromeyer closes.

"Military Surgery," he says, "cannot dispense with international help and mutual understanding. All civilised nations must labour to this end; it knows no political limits. Civil surgery is the *alma mater*, military surgery the ardent daughter, whose progress is difficult, because of the new impediments constantly produced by warfare. The common question is always presenting itself: What use can we make of civil surgery in the field? And the constant answer is: All that is possible in the circumstances! To comprehend this, demands character rather than learning. The English and Americans are people who are full of character; and therefore military surgery has to thank them for much. In the development of character, there are among them two powerful elements—national feeling, and a liberal education. Of their work on the field of battle and in the war hospital, Mac Cormac's book gives us a picture, of which spontaneity might be regarded as the central light. Each man knows what he has to do, without an order. Therein lies the sympathetic character of the work; it is not the learning that asserts itself, but the philanthropic heart. It bleeds sometimes; but the clear head retains its sway.

"Farewell to the Anglo-American Ambulance! I send its members my most friendly greetings, far over land and sea! Farewell too to thee, military surgery, to whom since 1848 I have devoted so many hours by day and by night! I could not regret, because I felt beforehand, what befel Germany. It is over!

"A long, honourable peace, may reward its heroes: military surgery will not then perish. It has, as Mac Cormac says, no mysteries for the civil surgeon, if he stand on the height of his time!"

A BOARD of Health has been formed at Thame, Oxfordshire.

THE autumn registration at the Apothecaries' Hall commences on Monday, the 2nd, and terminates on Saturday, the 14th of October.

OLD King's College men will hear with regret the announcement of the death of their late able and respected Principal, the Rev. Dr. Jelf.

THE names of Peter Eade, M.D., and of G. W. W. Firth, Esq., have been added to the Commission of the Peace for the City of Norwich.

THE Ceylon Medical School has now commenced its second session. The benefits of such an establishment in the island will be great.

DR. SILVER has been appointed Physician to the Charing Cross Hospital.

DR. W. J. STOTT's salary as medical officer of the Haslingden Union has been augmented £35 a year.

DR. BUCHANAN, of the Medical Department of the Privy Council, has been appointed to make a special inquiry into sanitary matters in Birmingham.

A NAVAL medical professorship is about to be established at Netley Hospital, and seventeen additional students, nominated by the Admiralty, will shortly join the school in Southampton water. Dr. MacDonald Fox is spoken of as the new professor.

MR. H. W. JACKSON, senior assistant medical officer, has given a completely satisfactory answer to the charge of cruelty at the Surrey County Lunatic Asylum, to which we last week referred.

THE inquiry as to the Hampstead Small-Pox Hospital was postponed from Tuesday till Thursday. We give elsewhere an account from our own reporter of Thursday's proceedings.

WE hear that Mr. Harry Leach has been requested by the Thames Shipping Inspection Committee to sketch out a system of sanitary surveillance of the port of London in accordance with the recommendations of the Privy Council.

WE are assured that there is no foundation for the many statements which have been afloat as to the prevalence of contagious diseases at Harrow. It must be said, however, that the neighbouring districts are not in a satisfactory condition, especially Edgware.

THE deaths registered in London last week were 1,422 in number, which was fifty-five above the average. The fatal cases of small-pox, which in the six previous weeks had been remarkably stationary, and had averaged eighty-four, declined last week to fifty-seven.

A CORONER's jury at Southgate, near Rotherham, has returned a verdict of manslaughter against William Collinson, a chemist at Rotherham, for causing the death of a young woman named Attley by an operation performed for a criminal purpose.

THE *Times of India* reports that news has been received from Zanzibar that Dr. Livingstone had again been heard of to the west of Lake Tanganika, whence he had sent to Ujiji, requesting his supplies to be forwarded. A young American was hurrying on by forced marches to Ujiji, in the hope of carrying relief to the traveller.

DR. HENRY ALLEYNE NICHOLSON, late lecturer on Natural History in the Medical School of Edinburgh, and author of a *Manual of Zoology*, a *Text-Book of Zoology*, and other scientific works, published by Messrs. Blackwood, has been appointed Professor of Natural History in the University of Toronto.

THE Secretary of State for War has appointed William Walter Weld, Esq., Surgeon-Major, to be Visiting Surgeon for Chatham, Gravesend, and Maidstone, under the Contagious Diseases Acts, 1866 to 1869, *vice* Francis Hastings Baxter, M.D., Surgeon-Major, appointed Physician and Surgeon to the Royal Hibernian Military School.

A RETURN has been published showing that 6,562 deaths occurred last year in the twenty-nine workhouses of the metropolis, and 413 inquests were held. Of this number more than one-half, 207, were held in St. Pancras. In only three other workhouses did the inquests reach 20. These were—Whitechapel, 41; Bethnal Green, 27; and Holborn, 20.

#### FEMALE MEDICAL STUDENTS IN MOSCOW.

It is officially stated that the Faculty of Medicine of Moscow, with the full concurrence of the Council of the University, have decided to grant to women the right of being present at the educational courses and lectures of the Faculty, and of following all the labours of the Medico-Chirurgical Academy. The tests of capacity will be precisely the same as for male students. The emperor has issued an order enlarging the existing institutions for instructing women in midwifery, and authorising them to act as surgeons, to vaccinate, and to be employed as chemists.

#### THE MIDDLESEX HOSPITAL.

FOR the vacancy in the appointment of Assistant-Surgeon to the Middlesex Hospital caused by the promotion of Mr. Lawson, several candidates have already come forward; but, as the election is quite an open one, no doubt other gentlemen will appear in the field. The following gentlemen are, we believe, candidates: Mr. Churchill, Mr. R. W. Parker, and Mr. Roberts.

#### GOVERNMENT GRATUITIES.

THE public vaccinators of Wolverhampton have received the following Government grants for successful vaccination, viz: Mr. F. Dunn, £46:15; Mr. T. Steward, £49:12; Mr. G. N. Smith, £38:19.

#### THE BERKSHIRE CAMPAIGN.

WE are glad to state that the troops employed in the Berkshire manoeuvres have been remarkably healthy; in fact, the hospitals at Aldershot have diminished as to the number of sick since the manoeuvres commenced. All sick requiring treatment have to be transferred to Aldershot.

#### PROSECUTIONS UNDER THE VACCINATION ACT.

AT the last Bridgwater petty session, William Henry Roberts, coach builder, and Edwin James Bovett, veterinary surgeon, were summoned for having neglected to have their children vaccinated. Mr. Roberts said, in defence, that vaccination did not prevent small-pox, that it was a dangerous operation, and that compulsory vaccination was an infringement of the liberty of the subject. Mr. Bovett said he was afraid that if he had his child vaccinated it would be diseased. An order was made in both cases for the children to be vaccinated within fourteen days, and the defendants to pay costs.—George Newcomb has been fined twenty shillings and costs (second time) at the Middlesborough Police Court for refusing to have his child vaccinated.

#### THE HAMPSTEAD SMALL-POX HOSPITAL.

THE case of the child, Elizabeth Bellue, who was lost at the Metropolitan Asylums District Hampstead Hospital, again came before Mr. Justice Brett, at Chambers, on Tuesday, on an application to issue a writ of habeas corpus for the production of the child. Mr. Bridge, who appeared for the officials of the hospital, read affidavits giving a history of the origin and objects of the hospital, and stating that the ladies of the East Grinstead Sisterhood, a Protestant community, had attended the hospital. The child, he said, was not in the hospital, nor under the control of the authorities of it, and they had done, and were willing to do, all in their power to find it. A detective officer had been employed, who had traced out all the children of the age of Elizabeth Bellue who had been in the hospital, and had not succeeded in finding her. Those who had died in the place had been accounted for. The only inference was that when the door was open the child had got away. Mr. Wright, who appeared for the parents of the child, contended that his learned friend had proved the case for him. He

had been informed that there was an entry in the books of the hospital that the child was discharged on the 31st of May. The child might have been sent to some convent. His lordship asked whether it was supposed that some of the ladies who had attended at the hospital had given up the child to some convent; and Mr. Wright said such was the suggestion that he was instructed to make. Mr. Justice Brett said he should give the ladies time to answer the allegation, and ordered the case to stand over.

#### ASSOCIATION FOR PROMOTING THE EXTENSION OF THE CONTAGIOUS DISEASES ACT (1866) TO THE CIVIL POPULATION.

A BRANCH of this Association has just been formed in Hereford to aid the extension of the "principles of these Acts". Seven gentlemen in the profession—Dr. Bull, Messrs. Hanbury, Lane, Moore, Griffith Morris, Thomason, Vevers—have joined, and it is anticipated that others will send in their names, besides clergy and laymen. We hope that the subject will be brought under the notice of the local profession at their annual dinner, which will be held in Hereford on the 26th inst. Already the opponents of the Acts are busy at work in Hereford. We trust that since it has now become necessary to place the nature and scope of the Contagious Diseases Acts fairly before the public, prior to further legislation next session, many other towns will follow the example of Hereford, and also that the Branch Associations already formed will bestir themselves.

#### A NEW HOSPITAL TENT.

THE following description has been published of a new form of hospital tent, designed by Mr. Netten Radcliffe, of the Privy Council Office, and built by Messrs. Piggott, of 59, Bishopgate Street Without, which seems likely to render valuable service in facilitating the isolation of persons suffering from contagious diseases. The tent is oblong in shape, sixteen feet long by fourteen feet wide, and thirteen feet high to the ridge pole. It has perpendicular canvas walls, three feet six inches high, and above these it slopes the remaining nine feet six inches. It is supported by a ridge pole and three uprights, of which the middle one might be dispensed with, and encloses 1850 cubic feet. At each end the canvas will roll back from the middle to the sides, and the walls also roll up under the flies, so that air may be allowed to sweep through the whole tent from end to end and from side to side. The 224 feet of floor space will allow comfortable standing room for four beds, which may be variously disposed, either one in each corner or parallel to each other, with the bed-heads against one of the side walls. By shifting the beds according to the direction of the wind it would always be possible to have three sides of the tent completely open. The whole tent, with poles, pegs, and guy-ropes complete, is supplied by Messrs. Piggott for £13:10. It weighs about a hundred weight, and can be completely fixed by three men in fifteen minutes. At a time when there is every probability that temporary cholera hospitals will be required in many places, and when the practice of isolating persons suffering from infectious disease is being much advocated and pursued, it is quite worth while to call the attention of local authorities to a tent far more convenient than either the bell tent or the old hospital marquee, and capable of affording so much accommodation for the sick at so cheap a rate. Mr. Radcliffe points out that a single tent may be regarded as an unit of temporary hospital construction, and that one may easily be fitted up as a nurse's dormitory or a kitchen or for any other administrative use, or may be subdivided by a partition so as to fulfil more than one purpose of the kind. Messrs. Piggott have made ample provision for ordinary ventilation in the sloping roof; and, against colder weather, they supply also a jean lining, at £9:10 additional. During the Crimean war Mr. Radcliffe had great experience of tent and most other forms of temporary hospital construction, and he has now sought to bring this experience to bear upon the supply of an urgent want. For severe small-pox or other cases in which the demand for fresh air is very great, he suggests that only two beds should be placed in each tent, but for all ordinary cases four may be regarded as the proper complement.

## SALE OF POISONS.

At the Clerkenwell Police Court on Saturday, Mr. Lloyd Rayner, a chemist, of New North-road, Islington, was fined £5 for selling oxalic acid in a packet labelled "effervescent citrate of magnesia." A shoemaker sent his son to the defendant's shop for a pennyworth of oxalic acid, an article which he used for putting a bright red on the heels of ladies' boots. When the boy returned, the man was surprised to see that the packet was labelled "effervescent citrate of magnesia." He immediately went to the defendant and asked him whether a boy had bought a pennyworth of oxalic acid at his shop that day, and he replied in the negative. The shoemaker handed him the packet of oxalic acid, and asked him whether the label containing the words "effervescent citrate of magnesia" had been sent out by him. The defendant examined the packet, and said it was very probable that some citrate of magnesia had been sold by him. When the shoemaker drew his attention to the fact that the packet contained oxalic acid, the defendant said it was a mistake likely to occur, and that it was very easy to make such a mistake, as the printer sent in the labels all together, and sometimes one got mixed with the other. Several medical gentlemen gave the defendant an excellent character for the last fourteen years, and stated that he was most careful in the performance of his duties. Mr. Cooke said it was much to be regretted that a man who had received such a high character as the defendant should sell oxalic acid and label it citrate of magnesia. It had been stated that the mistake had been made through the labels having been accidentally mixed by the printer, but if it was known that this was a frequent occurrence, chemists ought to be more careful. He should not be doing his duty if he did not inflict the highest penalty.

## THE BRITISH INFIRMARY AT NAPLES.

**BITTER** laments are uttered in the political journals, by British residents at Naples, over the decadence of the British Infirmary for Seamen there, from want of funds and discouragement by the Italian Government. According to Miss Gallwey, by whose father, Captain Gallwey, it was established, this little hospital, supported by voluntary contributions, and generously attended by the local English medical men, has relieved thousands of our sailors, and worked untold good. Previously to its establishment, she says, all distressed British subjects, when ill, "had to be taken to the native hospitals, where operations upon patients were wont to be performed in their beds adjoining those occupied by other sick. Cries extorted by direct agony—there was no chloroform in those days—were brutally checked, and even punished, by the operating surgeons. Well aware of these horrors, Captain Gallwey, assisted by some of the English residents, never rested until the little Infirmary for British Seamen was established." She adds indignantly: "Will our country now suffer its doors to be abruptly closed, and the sick consigned to the tender mercies and ignorant treatment prevailing in Neapolitan establishments? I cannot think so, or I should even rejoice that my poor father has been spared the bitter knowledge that all his labours have been undone. Surely the Government of King Victor Emmanuel will not prove less tolerant than that of Ferdinand II." Miss Gallwey is not altogether just in her indignation, and we apprehend that her statements concerning Neapolitan surgeons are not founded upon personal observation; but she pleads well, if not wisely, and for a good cause; and we hope she will succeed.

## CORONERS' JURIES.

**SOME** Holborn jurors grossly misbehaved themselves last week, and insulted the Coroner of Central Middlesex. He showed dignified firmness. We quote the following comment from the *Pall Mall Gazette*.

"There are few of our public functionaries to whom we have more reason to be grateful than our coroners. They are indefatigable in their performance of a very unpleasant duty, and frequently drag to light abuses which, were it not for their energy and acumen, might flourish unperceived for years, scattering misery and death far and wide. Indeed, as we have before pointed out, no better training could probably be devised for a young man about to enter political life, and

anxious to obtain some insight into the real wants of the people of this country, than to go through a course of inquests under the tutelage of an experienced coroner, by which means he would learn more of the grievances of the working classes in a month than if he attended Hyde Park and Trafalgar Square meetings for a century. We are glad, therefore, to observe that Dr. Lankester, who, when holding an inquest on Monday afternoon, met with insubordination and insults from some of the jurymen who had been summoned, upheld the dignity of his office by threatening to give the offenders into custody if they persisted in their misconduct. Inquests are far too solemn occasions for unseemly remarks and coarseness of demeanour; although they are generally held at public-houses, jurymen should endeavour, if only for the moment, to rise above the level of the pothouse, and remember that they are engaged in an investigation which, from its nature and importance, should at all events be carried on with some show of decency."

## BABY-FARMING.

A **SHOCKING** case of baby-farming was investigated by Mr. Hardwicke at the House of Detention, Clerkenwell, on Saturday. The infant on whose body the inquest was held was the child of Agnes Anderson, aged 17, and now an inmate of the prison. It was stated that the father of the child never contributed a shilling towards the support of either the mother or the child, which was born in the workhouse. Three weeks after its birth it was placed by the mother with a Mrs. Baker, of 16, Colville Place, to whom seven shillings a week was paid for its keep, but it was afterwards taken to a Mrs. Smith, who had it for a week, and received six shillings and sixpence. The poor child was subsequently taken back to Mrs. Baker, and was there (according to the medical evidence) so neglected and badly treated that it died in the prison infirmary from starvation. Mrs. Baker, it was stated, lived in the front kitchen, which was damp and unhealthy, and totally unfit for the habitation of any human being. In this place seven persons lived. The mother had been in the habit of taking the child out at night, and representing that it was dead, and that she wanted money to bury it, and on more than one occasion had said, "That she wished the child would die." The officer who had charge of the case having stated that Mrs. Smith did not appear to be a guilty party, and that she would be a useful witness against the other prisoners, the jury returned a verdict of manslaughter against Anderson and Baker.

## THE CULTIVATION OF IPECACUANHA.

**PROFESSOR BALFOUR** of Edinburgh has submitted to his fellow-botanists and physicians some observations on the cultivation of ipecacuanha in the Edinburgh Botanic Garden for transmission to India. As a curative for dysentery, the value of this plant is very great; and, in consequence of the partial failure, from various causes—such as the rashness and carelessness of collectors—of its cultivation in its native country (South America), its cultivation here for sending out to India has become a matter of much importance. A difficulty, however, till within a short time ago, stood in the way of this design, as it had not as yet been possible to get the perfect seed of the plant, and its propagation was accordingly but slow. A short time ago, however, Mr. James M'Nab of the Botanical Gardens discovered that, by cutting the root of the plant under the ground surface, numerous new shoots could be got, and the plant so propagated much more easily and plentifully. It had thus been possible to send out a number of healthy plants to India, which it was hoped would be there equally successfully cultivated. Mr. M'Nab had also been endeavouring, with fair prospect of success, to get the perfect seed of the plant; and if that can be done, the difficulty of propagation will, of course, disappear. There are now two varieties of the plant in the Botanical Gardens, one of which has been cultivated there for forty years, and the other has just been got from South America, through the kindness of Dr. Gunning and Dr. Christison. It is hoped, from the union of these two varieties, to get a perfect seed.—In the course of the remarks made on this discovery, Dr. Cleghorn, F.L.S., late Conservator of Forests, Madras, expressed his delight at seeing the satisfactory result of the ipecacuanha propagation. Every army-surgeon, he said, knew the great value of this remedy

the treatment of dysentery; and he hoped that the result of this experiment would be as successful as had been the introduction of cinchona. He thought much credit due to Professors Balfour and Christison and Mr. M'Nab in this matter.

#### REMARKABLE EPIDEMIC DISEASE IN PERNAMBUCO.

DR. VELLOSO writes to the *Gazeta Medica da Bahia* of August 15th, that for some months there had prevailed in Pernambuco, where he was in practice, a remarkable form of disease, having some resemblance to beriberi, but differing from it so far as to lead Dr. Velloso to regard it as an hitherto undescribed malady. It had attacked persons in various parts of the city, and was epidemic in the house of detention. In that institution, of forty-eight persons attacked in the course of a few days, fourteen died; and it was necessary to remove the remaining inmates in order to prevent the spread of the disease. The disease is described as generally appearing suddenly in persons in apparently perfect health. Sometimes, however, there has been slight oedematous swelling of the lower limbs. Oedema appears in the ankles, and rapidly extends to the abdomen, thorax, and face; the patient presenting the appearance of a person suffering from the effects of intemperance in alcoholic drinks. In some cases there is fever, occasionally of an intermittent type. There is mucous and bilious vomiting. The abdominal muscles become so rigid that in most cases it is impossible to examine the viscera. There is paralysis of the muscles of the lower limbs, with at the same time such intense hyperæsthesia that the patients cry out on the slightest pressure. One patient could not even bear the touch of the bedclothes on his legs. Sometimes the paralysis extends upwards, affecting the hands. The disease makes rapid progress; and, sometimes within twenty-four or forty-eight hours, there is a most distressing sense of constriction at the base of the thorax. The sufferings of the patient are extreme; but the mental faculties remain intact. The urine is normal, and does not contain albumen. In most cases the bowels are constipated; sometimes there is diarrhoea. The dyspnoea which attends the progress of the oedema passes into orthopnoea, generally accompanied with a suffocative cough and expectoration of greenish mucus streaked with blood. There is much anorexia from the beginning. The patients complain of slight formications in the course of the nervous plexuses; and, when slight convulsions set in, they die asphyxiated or comatose. On *post mortem* examination, the principal organs do not present any morbid change, with the sole exception of hyperæmia of the mucous membranes. There are effusions in the serous cavities, and much infiltration of the areolar tissue. In some instances there has been found sanguineous engorgement of one of the lungs—due apparently to the mode of termination of the disease. The etiology of the malady is obscure. It cannot be attributed to causes inherent in the house of detention; for, before it appeared there, several cases were observed in various parts of the city, in persons situated in apparently the best hygienic conditions. Dr. Velloso suggests that there may be some connexion between the disease and the excavations which have been carried on in Pernambuco, in the course of which some old cemeteries in various parts of the city have been opened. No treatment, either rational or empirical, has hitherto been found successful. The government of the province has nominated a commission of seven members to study and report on the disease.

#### THE ORIGIN OF ENEMATA.

We referred lately, on German authority, to the astonishment of the Bavarian soldiers at the ubiquity of the "irrigateur" in French establishments, and the odd uses to which they put them. Frederigo Kernot of Naples, in a newly published *Storia della Farmacia*, describes "with true Southern liveliness," according to the *Pharmaceutical Journal*, the invention of the enema-apparatus, which he looks upon as an epoch in pharmacy as important as the discovery of America in the history of human civilisation. The glory of the invention of this instrument, so beneficial to suffering mankind, belongs to an Italian, Gatenaria, whose name ought to find a modest place together with

Columbus, Galileo, Gioja, and other eminent and illustrious Italians; he was a compatriot of Columbus and professor at Pavia, where he died in 1496, after having spent several years in the perfection of his instrument. The enema-apparatus may be justly named the queen of the world, as it has reigned without a rival for three hundred years over the whole continent, besides Brazil and America. The enema came into use soon after the invention of the apparatus itself. Bouvard, physician to Louis XIII, applied two hundred and twenty enemata to this monarch in the course of six months; in the first years of Louis XIV, it became the fashion of the day; ladies took three or four a day to keep a fresh complexion, and the dandies used as many for a white skin. Enemata were perfumed with orange, angelica, bergamot and roses; and Mr. Kernot exclaims enthusiastically, "Oh! se tornasse questa moda" (oh, that this fashion would return)! The medical profession at first hailed the invention with delight, but soon found the application *infra dig.*, and handed it over to the pharmacist; but shameful invectives, sarcasms and epigrams, hurled at those who exercised the humble duty of applying the apparatus, made them at last resign it to barbers and hospital attendants. As a specimen of these epigrams, the author gives the epitaph on a tombstone of an ancient pharmacist:—

"Ci gît qui pour un quart d'écu  
S'agenouillait devant un cu."

#### SCOTLAND.

THE foundation-stone of the new hospital for Lanark was laid last week.

WE regret to hear of the death of Mr. John Duncan, of the well-known firm of Duncan and Flockhart, Edinburgh. During his lifetime he enjoyed the esteem and respect of a large circle of medical men in the city.

#### SMALL-POX AND FEVER IN DUNDEE.

THE inhabitants of Dundee are somewhat alarmed at the increase of small-pox and typhus fever in their city. In the Infirmary there are about thirty cases of small-pox, and nearly ninety patients suffering from typhus fever. Steps are about to be taken to erect a temporary hospital.

#### IRELAND.

THE Mayor of Cork has had the Cross of the Legion of Honour conferred upon him in recognition of his services in connection with the succour of the French wounded in the late war.

FOOT-AND-MOUTH DISEASE continues to prevail amongst the cattle in some of the districts of Derry and Tyrone. It would be interesting to know if the inhabitants of the district are infected with the disease.

#### SANITARY PROSECUTIONS.

MR. JAMES KENNY and Mr. John Doyle were lately summoned for allowing two tenement houses to get out of repair. Dr. Mapother stated that the premises were dangerous to health and life. The Mayor allowed three weeks to put the place in repair.

#### ADULTERATION OF MILK.

ELIZA NIELL, Patrick O'Neill, and Mrs. Grenell, were summoned this week for adulterating milk. Dr. Cameron found thirty-three per cent. of water. Mr. O'Donnell observed that this system of adulteration deprived citizens of food and proper nourishment, and that he should inflict punishment according to the amount of adulteration. Fines were inflicted in all cases. Mr. Fitzgerald, sen., in conducting the defence, observed that the authorities at Liverpool are not quite sure whether they are legally empowered to punish those who sell milk watered to the extent of seventy-five per cent. The mixing water with milk, according to Dr. Letheby, is not adulteration. Water, he states, is *per se* wholesome. The *Irish Times* observes that "what is whole-

some for one may be deadly to another. The deaths of infants are numerous in London caused by the wretched milk retailed to the humbler classes. He who supplies milk watered seventy-five per cent. to an infant child really kills the child by starvation. The Liverpool authorities may safely punish the delinquents they have detected. They sold an article deleterious to human health, and should suffer the penalty."

#### SANITARY STATE OF DUBLIN.

THE "sanitary tour" of Mr. Benson Baker has produced a very wholesome amount of agitation. It has stirred up a degree of interest in sanitary matters which must be productive of good effects. Dr. Grimshaw has come forward to attest the accuracy of Mr. Baker's statistics of zymotic disease, which had been hotly impugned; and to support with his independent testimony the general truthfulness of the picture which he has drawn. The press generally has accepted, from its own knowledge, these statements of Mr. Baker as well founded. One journal has had the sanitary condition of Dublin specially investigated by a gentleman who accompanied Dr. Grimshaw through miles of streets, lanes, and alleys. The picture which he draws from the life is certainly not less darkly coloured than that sketched by Mr. Baker. The facts, indeed, seem indisputable, and speak for themselves. The natural situation of Dublin is admirable. Nature has done everything to make it healthy. Man is responsible for the filth which poisons the soil, air, and water; for the fever which is now the naturalised denizen of the city; for the "filth-bred" infections which mow down its population in unnatural numbers. The Corporation are slowly awaking to a sense of their past shortcomings; they are even attempting to remedy them after a fashion. Thus they have fined some persons for throwing filth into the streets, hitherto a venial offence; but, as they have not yet thought fit to compel landlords to make their houses habitable by providing receptacles (under the Towns Improvement Act), this is an illusory piece of activity. Meantime they are themselves the greatest offenders, inasmuch as the receptacles which they provide for the putrefying refuse of the streets are left to ferment and to breed stench and poisons in dépôts placed amidst crowded centres of population. We observe also some increased activity in reference to tenement houses which have fallen into a condition dangerous to health and life. All this small pottering will do little. Small spasms of temporary activity are indications of systemic feebleness rather than strength. To make a good beginning, let the Corporation act upon the powers given to them by the Sanitary Act of 1866, authorising them to employ and pay the dispensary physicians to assist in the sanitation of the city. Their daily work brings the dispensary physicians into daily contact with the zymotic diseases of the poorer classes (which spread, be it remembered, from the poor to the rich), and lays bare the material and removable causes of the disease. They alone can form an efficient and complete sanitary staff. The Corporation have evidently a dim sense of this truth, inasmuch as they have forwarded a circular with enclosed post-cards, asking for sanitary information from the dispensary physicians gratuitously. This is somewhat too strong a burlesque of activity to be sincere. Suppose they were to have attempted the census in the same way, and to have sent begging cards to a variety of gratuitous enumerators, there would have been good reason to doubt their desire to have a complete and satisfactory census. At any rate, it would have been clear that they had hit upon a very poor device. A great public work is not to be carried on by sending round the hat. It is particularly shabby to appeal to the feelings of the underpaid and overworked dispensary physicians, and to ask them to add gratuitous sanitary inspection and reports on a systematic scale to their heavy and ill remunerated labours. The Act gives the Corporation power to employ and pay the dispensary staff as sanitary officers. If they be in earnest, they will do so. At present, they spend more than twice as much on their fire-engines as on the sanitation of their city. No expenditure could be more economical than that which promotes health, arrests zymotic diseases, protects the lives of the innocent and the able-bodied bread-winners, purifies the city, and saves the rates.

## NOTES OF A SANITARY TOUR THROUGH DUBLIN.

### II.

THE fatal activity of milk, as a carrier of disease, has been most carefully and scientifically investigated by Dr. Taylor of Penrith, Dr. Ballard, Dr. Bell, and Dr. Thorne Thorne. It has been conclusively shown that typhoid fever, scarlet fever, and even cholera, have been communicated to people through the medium of milk. It is, therefore, of the utmost public importance to inquire into the sanitary condition of the cow-sheds and dairy-yards. In the most densely populated and fever-infected district, in close vicinity to the Corporation manure dépôt in Marrowbone Lane, are to be found the cow-sheds and dairy-yards of Dublin. These yards, like the neighbourhood, are abominably filthy. Manure is allowed to accumulate in heaps, from which may be seen small black foetid streams flowing into the open streets. The effluvium from these yards is absolutely poisonous, and is only equalled by the atmosphere in the cow-sheds. In this district man and beast alike fall easy victims to preventable disease.

Dr. Cameron says that the loss from pleuropneumonia sustained by Dublin dairymen is at least 10 per cent., yet the dairymen cannot be convinced that the disease is contagious; and, therefore, unless under compulsion from the sanitary authorities, they never disinfect their premises after the removal of diseased animals from them. The vital powers of the cows are lowered by their constant respiration in close foetid stables. In some of the sheds the cubic space allowed for a large cow is less than the *minimum*—viz., 300 cubic feet of breathing room—allowed a man in a registered lodging-house. The cows were so close to each other that it was impossible they could all lie down together. On questioning the owner on this point, he facetiously replied, "Gorra, sir, they take it turn about." This repartee might excite a laugh if the occasion of it did not inflict cruelty on the beasts, and tend to infect the people with disease. It is not surprising to learn that milk obtained from cows herded together in such unsanitary conditions not only conveys foot-and-mouth disease, but typhoid and other zymotics, to the consumers.

An enormous amount of diseased meat is sent into Dublin. The most ingenious devices have been resorted to to supply the market with diseased meat. All manner of vehicles are used; and on one occasion Dr. Cameron says that a hearse was employed; the contents, two bad carcasses of beef, were discovered.

During the past year, 388,380 lbs. of diseased meat were seized in Dublin, but it is very certain that a large mass eludes seizure. On visiting one of the rural districts within ten miles of Dublin, I elicited, by inquiry, that when cattle were found to be diseased the police had precautions taken for killing them: this being accomplished, their responsibility appeared to cease, and the carcasses were forthwith sent into Dublin, *ostensibly to the knackers*. An arrangement appears to exist that the metropolitan police should examine certain carts coming into the city, and a few are told off for this purpose. Those carts that are caught bringing diseased meat into the city are of course going to the knackers, but those that succeed in running the blockade find a ready and profitable market for their diseased freight, which is sold to the poor for food. During the past year four persons were imprisoned for selling bad meat, and forty-two were fined for the like offence. The penalty inflicted is so inadequate, when compared with the criminality of the act and the injury inflicted on the poor, that as yet it has had but a small deterrent effect. A woman, who was an old offender and frequently before the Lord Mayor's Court, was let off on the payment of ten shillings, so that she may again follow the nefarious but profitable trade in unsound meat. It is strange, but none the less true, that you may poison with diseased meat and be let off with a fine varying from a shilling to a pound; but commit the like offence with a vegetable or mineral poison, and you will be tried for wilful murder or manslaughter, or the administration of a deleterious substance.

Dr. Cameron has stated that during five years before the appearance of lung-distemper, the annual deaths from phlegmons averaged five per 20,000 deaths from all causes; whilst during the ten years ended in 1856, the mortality from these diseases rose to 162 per 20,000 deaths. He further observes, that measly pigs are very common in Ireland—much more so than in either England or Scotland. Measly pork is likely to be used in the preparation of sausages. It is not a pleasant reflection that when eating a sausage we may be possibly introducing into our body the embryo of a tapeworm ten yards long. Even kitten pies are innocent compared with diseased meat that may introduce tapeworm, or worse, the

*trichina spiralis*, which may prove fatal to the consumer. Why should measly pork be more common in Ireland than elsewhere? May it be due to the fact that pigs are kept in such close proximity to the dwelling-houses, and that these cysticerci are thus constantly changing their habitat from the animal to the human subject, and *vice versa*?

The sanitary arrangements for Ireland require to be recast. It is necessary to have a revision and consolidation of sanitary laws. It is a well ascertained fact, that local boards are more inclined to be obstructive than to cheerfully and efficiently aid the health-officer in carrying out what he knows to be of paramount importance to the health and well-being of the citizens. This is a result of opposite personal interest and division of authority. The chief responsibility of the breakdown of sanitation must be laid on the system which establishes no real regulative and controlling authority over various corporate boards and local commissioners. Nothing will efficiently be done for Ireland until a ministry of health shall be established, which shall co-ordinate the various departments and authorities that at present direct the sanitation of the State.

The appointment of a medical health-commissioner for each of the four provinces, and two engineers, associated with the Poor-law Commissioners, with authority to control local corporate and other authorities, and with power under sealed order to enforce necessary sanitary work to be done, would doubtless in a few years produce results as economical and humane as that which has issued from the admirable working of the Irish Dispensary and Medical Charities Act. This board would be for Ireland a single central authority for the prevention and cure of disease, as well as a board of appeal for the various local boards.

Under a new régime, the appointment of the dispensary-physicians as the health-officers of their respective districts would be of the greatest possible advantage. They possess the earliest knowledge of preventable disease; they are daily in contact with those who suffer most. I witnessed their efforts to educate the people on the necessity of vaccination; and admired their short pointed lectures on dietetics and personal hygiene. My friend Dr. Maunsell has forcibly observed that the execution of sanitary measures comes naturally within the province of Poor-law administration, since disease in any shape tends to create distress and destitution, the relief or prevention of which is, or ought to be, the especial object of every poor-law. But the powers to enforce their execution must rest in some other hands than those of local authorities, who may themselves be interested parties. The Poor-law medical officer, by virtue of his office and duties, will be the most likely person to detect nuisances—the first to know the existence of epidemic, and the proper person to ascertain its cause. But as long as the medical officers are appointed and paid by boards of guardians—and consequently under their control—it will not be their interest to call attention to the existence of nuisances, which may perchance bring them into antagonism with the board, or individual members of the board, of guardians. The consequence is, that both the detection of nuisances and the enforcement of nuisance-law have come to a dead lock; and one of the results is, that 25 per cent. of our total mortality is due to preventable disease.

When the Poor-Law Service shall be placed on a similar footing to that enjoyed by our brethren in the army and navy, then will the service be efficient. Let admission to the ranks be through the portal of competitive examination. Let it be a *sine qua non* that a competent knowledge of medicine, surgery, midwifery, and state medicine be adduced by all the candidates. In state medicine, the University of Dublin has taken the initiative. This university has read the signs of the times, and is prepared to lead in the van of advancing sanitary science. The Poor-Law Medical officers must be paid entirely out of the Consolidated Fund, with increasing pay for length of service, and a certain superannuation if incapacitated through disease or age. There should further be promotion from the ranks to borough or county health officer, and to that of provincial commissioner. This would be a strong and efficient incentive to active sanitary exertion in this department of the Civil Service. In Ireland there appears to be a special provision for the appointment and payment of the dispensary physicians, as health-officers, under the Sanitary Act of 1866, which says:—"Whenever, in compliance with any direction or regulation of the Poor-Law Commissioners, which they may be empowered to make under the laws for the time being as to the public health, if any medical officer of a union or dispensary district, or any other medical practitioner specially employed by the guardians for the purpose, shall perform any extra medical service in any union or part of a union, it shall and may be lawful for the guardians of the union to determine, subject to the approval of the said commissioners; and if they shall not approve the amount determined by the guardians, for the said commissioners to fix by order under their seal, such remuneration proportioned to the nature and extent of such services as aforesaid, as to them shall appear

just and reasonable; and the amount of such remuneration shall be paid to such medical officer, or other medical practitioner, by the guardians of the union out of the rates raised for the relief of the poor." By this act the description of sewers and nuisance authorities in Ireland, are for the city of Dublin the right hon. the Lord Mayor, aldermen, and burgesses, acting by the town council; for towns corporate, with the exception of Dublin, the mayor, aldermen, and burgesses, acting by the town council; for towns and townships having commissioners, the town and township commissioners; and for such part of each union as is not under another sewer or nuisance authority, the guardians of the poor of each union. That the sanitary law is not carried out as efficiently as it ought to be can hardly be questioned; and this is in all probability due to the fact that the nuisance authorities are both too numerous and irresponsible, and that the duties are in general performed by a policeman, a relieving officer, or some other amateur in hygiene, while the medical officer is the last person thought of with regard to sanitary arrangements, or if he is asked to report on the matter, he is expected to do so gratuitously.

There can be no doubt that, in the small towns and rural districts in Ireland, the dispensary physicians could, in addition to the attendance on actual disease, discharge the duties of health-officers, under provincial health-commissioners; but that, in places with a population like Dublin, Cork, Belfast, etc., it would be necessary to appoint in addition a gentleman, debarred from private practice, with an adequate salary, to devote himself entirely to the sanitation of the people, aided by the dispensary physicians.

BENSON BAKER, District Medical Officer,  
Christ Church, Marylebone, etc.

#### THE HAMPSTEAD HOSPITAL INQUIRY.

ON Thursday morning the special commissioners of the Local Government Board, Mr. Henley and Dr. Buchanan, opened an inquiry at the offices of the Metropolitan Asylums' District Board, Norfolk Street, Strand, into the charges made of mismanagement of the Hampstead Small-pox Hospital. These charges were first made, it will be remembered, in a letter signed by three gentlemen who had been assistant medical officers in the hospital, and affected particularly Dr. Grieve, the medical superintendent, although, of course, the whole management of the hospital was affected by the charges.

The complainants in the case, Mr. Greaves and his fellow-assistant medical officers, were represented by two counsel, Mr. Bucknill and Mr. Collins; the father of the missing child, Bellue, was represented by Mr. W. Wright; and Mr. Hammond represented the committee of the Hampstead Hospital and the Metropolitan District Board.

Mr. HENLEY, in opening the proceedings, stated that the course he and his colleague would adopt would be to take the charges made by the three medical officers first, and to go into them fully; then to follow with any other charges which might be made. He thought that, as he and his colleague were not trying the case, counsel would do well not to make addresses, though, of course, he should not bind them on this point.

Mr. W. WRIGHT applied for leave to cross-examine the witnesses relative to the child Bellue.

Mr. HENLEY, after a lengthened discussion of the point, decided to tell Mr. Wright the course he should adopt in that matter on the next day.

Mr. ATKINS then opened the case, by relating the statements made by the complainants.

The first witness called was evidently not of the poorer class for whom the hospital was intended. This was

James Henry Wills, of Dorset Place, Pall Mall, who stated—I was taken ill with the small-pox, and was taken to the Hampstead Hospital, on the 28th of February last. First, they would insist upon calling me "Wells" instead of Wills. When I was taken in I was run in on a trolley in my own shirt and guernsey, instead of hospital clothes. Soon after my admittance I was tied down in the iron bedstead, and I have the marks on my ankle now where I was tied down. It was about three days after my admittance that I was tied down. The persons who tied me down were a convalescent patient, who was acting as a nurse, and a nurse, a paid one, who gave me an "extra screw," which "extra screw," I believe, caused the mark on my ankle. The nurse who gave me the "extra screw" was a day-nurse, for a night-nurse would not have been able to do it, she being old and generally "screwy." I suppose the nurse came to give me the "extra screw" because I got loose, but that is as far as my memory serves me, for I was rather delirious. I don't remember how long I was tied down. It may have been twenty-

four or forty-eight hours for all I know. I think sheets were used in tying down, and I never saw anything else used for this purpose. I think Mr. Greaves untied me, and he said he did not agree with the tying down. After I was thus tied down I was in a most fearful state, as anyone may think, for I had not been moved for several days, and I was changed—that is, my things were changed. I was wiped, not washed, and put into the sheets. It was then that I was put into hospital clothes. While I was in No. 9 ward I saw several persons tied down, perhaps four or six, during four weeks I was in that ward. There were generally convalescent patients, who assisted as nurses, who tied down. This was in the acute ward. In regard to the food given to the patients, I saw that the nurse, when asked for drink, would walk away without answering. I have been kept for hours without drink, but not a whole night. The drink given was milk well watered—it was watered before it came to the hospital, and it was watered afterwards, so it was “double distilled” by the time it came to us. I have heard other patients complain of not getting drink. Then meat was served not fit for pigs. I could not eat it, and then I was served with what was called “boiled mutton,” on an ice-cold plate, without knife or fork. The potatoes were bad, but not badly cooked, and the bread was good, but very scarce. There were only two paid nurses to No. 9 ward, for the day, and one old woman for night, with thirty-seven patients; but sometimes they used to get a youngster from No. 4 (the convalescent) ward to assist, and this both at night and day. After I had been in No. 9 ward for some time I had an attack of erysipelas, and I was transferred from No. 9 to No. 12, which was a fever ward. There the nurse used to lower the gas, and bid us “good night,” and we had no attendance except that some one used to come in to keep the fire going. One night a poor fellow was taken very ill, and I got one of the patients off for assistance, but he was gone a long time, and I had the consolation of sitting up in bed, and seeing the man die. This must have been about the beginning of April, and the hour was between twelve and one o'clock in the morning. About five minutes after the man was dead the patient I had sent to obtain assistance came back, and Sister Frances came ten minutes after, and she asked my brother patient to assist her to lay the body out; but it was in such an offensive condition that he refused. The body was not removed until five o'clock in the morning. I cannot give the name or date. I don't know the name of the patient who refused to lay out the body.

The CHIEF COMMISSIONER said it was rather a vague charge for the hospital authorities to answer, for there was no name or date.

Mr. COLLINS said they had not the power to see the books, or even the complainant's own reports.

Mr. HAMMOND said he had offered all facilities with regard to the books, but the reports of these gentlemen had been kept back for obvious reasons. These gentlemen were going to be examined, and he had advised that their reports should be kept back.

Mr. COLLINS asked if he was confined to the charges made in the letter in the *Times*.

The CHIEF COMMISSIONER replied in the affirmative.

The witness's evidence was then read over, and he added to his former evidence, that the food supplied was “most vile, and not fit for paupers.”

Examined by Dr. BUCHANAN, he said the nurses were extra to the sisters, and he further stated that when the nurse left on the night when the man died, she told him she did not think the man would live. He did not know the name of the nurse, the date of the night, the name of the man who died, or the name of the man who refused to lay the body out.

Cross-examined by Mr. HAMMOND, the witness allowed that he had never complained to Dr. Grieve, whom he saw often, to Mr. Wyatt, or to any of the sisters, or to any one else, but he thought he mentioned something to “Dr. Greaves.” He allowed that when he was taken ill he had no one to attend him, but sent for the relieving officer, who sent him to Hampstead in the parish ambulance.

John Hunter, a publican's assistant, was then called, and he deposed that he was taken to the hospital on March 16th, and was discharged on April 27th. He then deposed to having been tied down at a time when he was delirious, and to finding himself tied down when he recovered his senses. He also declared that there was an insufficient supply of milk for the patients, and that he had often been disregarded when he asked for milk. Then the food was bad, and was insufficient in quantity, both meat and potatoes; and if he could have sent out for any food he would have done so. He had also seen vermin in the heads of patients. He had seen a boy with scurvy in his hands, and witness had seen maggots in the boy's hands. The witness said he was retained in the acute ward because he had abscesses, and, therefore, he could only speak as to one ward. He had not complained to Dr. Grieve, or to any one else, beyond Mr. Greaves.

Cross-examined, he said he had spoken to Dr. Grieve to complain of some stamps which were sent to him in correspondence, and Dr. Grieve listened to him, and made a note of the complaint. Even after that he did not complain to Dr. Grieve, nor did he complain to the superintending nurse, Sister Frances. He confessed he was admitted on a relieving officer's order; that he had gone away with the discharged nurse Sullivan; that he had taken her to his house; had given her a present; and had met other patients, who had assembled at his house, and would be called as witnesses.

Mr. Edwin James Barter, the son of a medical galvanist, of 5, Upper Montagu Place, Montagu Square, a clerk in the Ottoman Bank, City, stated that he became admitted to the hospital on May 24, and left there on June 19. While there he had seen persons tied down, and one particularly. This one was a delirious man, who tried to get out of window, and who, on getting loose, fell out of bed and cut his head. The witness said the food was not good, and was insufficient; but he had no complaint to make of want of drink at the nights. He complained of the potatoes being bad, and the meat being hard, insufficient in quantity, and badly cooked. He complained, too, that the bath-room was heaped up with dirty things, and that the patients emptied their dirty water into the bath.

On cross-examination, the witness allowed that he made no complaints to any one connected with the hospital, either while he was there or since he had left, about how affairs were managed. He acknowledged, too, that when he was discharged he asked Dr. Grieve to allow him to stay longer, and the doctor kindly allowed him to do so. He complained to his own father, when his father told him that the parish authorities had requested he should pay for his keep in the hospital.

Thomas Hatcher, now a waiter at 324, Strand, stated that he was an inmate of the hospital from the 2nd of March until the 2nd of June. He had seen persons tied down. He had had enough to drink; but he had complained to Mr. Kynaston of the quality of the meat. He had not complained to Dr. Grieve, though he often spoke to that gentleman, nor to Mr. Wyatt, or to other gentlemen of the committee, whom he often saw. He had seen the patients in that part of the building only have two towels among eighty-four of them, and these towels had vermin on them. These people washed in the kitchen.

Questioned by Dr. BUCHANAN, the witness allowed that there was an excellent lavatory a short distance off with good supplies of everything, and no one objected to the patients using it. Witness had the cutting up of the meat, and if there was not sufficient sometimes more was got from the kitchen, or a little was taken from each ration to make up the number of rations.

Cross-examined by Mr. HAMMOND, the witness admitted that he had solicited Dr. Grieve to permit him to stay in the hospital beyond the time when he was discharged. He did this because he could not have got a situation if he had gone out, as his face had not healed, and he was very grateful to Dr. Grieve for permitting him to stay.

The case was here adjourned till Friday.

## DISINFECTANTS.

A GOOD deal has been written lately on this subject in the public papers, by gentlemen whose knowledge is evidently not of the most sound or extensive character. Dr. A. J. Bernays, Professor of Chemistry at St. Thomas's Hospital, treats the subject magisterially and ably in the following memorandum.

In employing a disinfectant it should be borne in mind that we sometimes have to deal with bodies in a state of decomposition, evolving gases more or less known to chemists; at other times with matters not so advanced, in a solid state, but not volatile.

The gases evolved from putrefying animal matter, and those of most injurious quality, are generally hydrogen compounds. Now, these should be dealt with by volatile disinfectants; if possible by gases. Now, there is no gas to equal chlorine; there is none so cheap, so thoroughly effective in altering the character for good of noxious gases, and none so easy of application. As long as it is in excess, or, in other words, preponderates over the injurious hydrogen compounds, it can be recognised by its odour. There is only one serious objection to chlorine—its smell. But, if it be properly used, and not wasted, this objection is reduced to a minimum. Except in the case of closets, where it is best to dust a small quantity in the pan above the reach of water, a solution of chloride of lime, in the proportion of one pound to ten pound of water, is most adapted for disinfecting air. A rag as

large as an ordinary handkerchief steeped in such a solution, wrung out and suspended in small rooms, will sweeten the air for twenty-four hours. The chlorine, slowly evolved, acts partly in decomposing injurious hydrogen compounds, partly in evolving ozone; chlorine is, therefore, a grand oxydising agent.

I will not occupy your space by mentioning other gases, such as sulphurous and nitrous acids, but would only venture to point out that chloralum cannot be substituted for chlorine—a fixed, non-volatile substance cannot take the place as a disinfectant of volatile substances. When we come to disinfect decomposable matter, when it is our task to prevent such matter from decomposing, then we have generally to do with solid bodies. Here is my difficulty. How can I in a few words give an intelligible description? The compounds so capable of mischief are those which contain nitrogen, sulphur, and phosphorus; the best type of them we have in albumen, such as constitutes in a pure state white of egg. These albumen-like compounds form, doubtless, the germs about which so much is written by medical men. If, then, germs partake of the character of albuminoid bodies, for such there can be no better disinfectant than carbolic acid. Anyhow, as these bodies give rise to the most fetid gases; as they are abundantly present in all decomposing animal matters; and as they are completely coagulated by carbolic acid, it is very difficult to understand why carbolic acid is to be substituted by disinfectants which have no such power. The evil of carbolic acid is not in its poisonous nature; many more have been killed by chloride of zinc, which is nearly equal to chloralum. No, rather is it to be sought in the deceptive character of common carbolic acid. The impurities give the disagreeable and often disgusting smell, and the odours attaching may give quite a false notion of security. Sprinkled against bricks in a sewer, out of reach of water, all the smell supposed to proceed from carbolic acid may continue to be evolved for months, whereas nothing in the way of disinfection is being accomplished. A purer article at a much higher price would be really cheaper, because effective.

In conclusion, carbolic acid is readily diffused through air; chloralum is not. Both are good in their place; but the latter can no more pretend to take the place of carbolic acid than carbolic acid that of chloralum. Carbolic acid may coagulate germs and render them harmless; chloralum could do nothing of the kind.

### THE GERM-THEORY OF DISEASE.

THE following is extracted from a manuscript paper read six years ago before the Medical Society of Middlesex Hospital, by Robert Liveing, M.D., on the Pathological Relations of "Fever."..... I have assumed throughout that the diseases under consideration all depend on some poison introduced into the system from without; it is merely an assumption, as we have no definite proof that such is the case (except, perhaps, with regard to small-pox). But, admitting the truth of it, we are led unavoidably to the conclusion that this poison is capable of increase when introduced into the animal economy. This, at least, must be true with regard to the contagious fevers, for the opposite supposition will obviously involve anomalies the most improbable; for example, that the whole amount of virus which has been introduced into a new population, previously existed in the individual who brought the infectious disease into the country.

If, then, the virus is capable of increase, it seems almost certain that the mode of increase must be by growth—in short, that the poison must be an *organised poison*, each organic particle of which must have a definite period of existence, and then die a natural death; and, indeed, we may go further, and say that, in all probability, only during a comparatively short period of its existence can the ultimate organic particle of the virus propagate its species. The history of vaccination will fully bear me out in this supposition. The fixed period of incubation and definite course which most of these fevers run, also favours the same conclusion.

It may be said in answer, that the same arguments which would prove the organised nature of the poison in contagious fever, would apply to such diseases as gout and rheumatism, which we have other reasons for believing to be associated with, or dependent upon, some unorganised poison. In reply, I do not admit that a fair parallel can be drawn between such diseases as gout and rheumatism, and the contagious fevers. In the former, the poison is evidently generated in the system itself, and is not introduced from without (or, at least, not in the same way as in the contagious disorders); it is probably the result of malassimilation and defective excretion; and it may even yet be doubted, in spite of some experiments to the contrary, whether the poisons of gout and rheumatism may not themselves be organised. I do not wish, however, to imply that I believe such to be the case.

With regard to the malarial poisons, it is more difficult to prove their organised nature; it is not so obvious that they increase after introduction into the human body, and, therefore, arguments based on such a foundation fall to the ground. But there are other facts which lead us to the same conclusion: the localisation of the malarial poison to certain districts; the necessary condition of a certain elevation of temperature for its development; and, what appears to me the strongest argument of all in favour of this view, namely, the apparent incompatibility of the co-existence of this poison with certain congregated forms of animal life, such as the central part of well populated towns. It seems as if the congregating together of inhabited houses effectually excludes or destroys the vitality of the malarial virus of intermittent fever. In no place is this better seen than in Rome; the central part of this city is perfectly free at all seasons of the year from malarial poison, although it abounds in a concentrated form almost within a stone's throw of those spots which are perfectly healthy; while it will apparently traverse ten times the distance of country without losing any of its injurious effects. This fact is accounted for satisfactorily only on the supposition that the malarial poison is organised, and of vegetable origin.

### ELEGANT PHARMACY.

OUR American colleagues take more pains than we do to disguise the unpleasant flavours of medicines, and to prescribe them in elegant forms. This and other causes have led to an inconvenient extension of the habit of prescribing proprietary elixirs and preparations of known composition, but varying according to the taste and skill of the makers who introduce them. The Newark (New Jersey) Pharmaceutical Association has issued a formulary of elixirs and non-official preparations, by which they propose to dispense all such compounds, unless specially directed otherwise by the prescriber. One or two are worth notice, as the following.

*Wine of Beef and Iron.*—℞ Extracti carnis (Liebig's) 1 oz.; ferri citrat. 96 grs.; vini Xerici 16 oz.; syrupi 2 oz.; pimentæ (contus.) ½ dr.; Aquæ q. s. ft. 24 oz. Dissolve the extract of beef in 4 oz. of water and add the allspice; after standing ten hours add the wine and syrup, then the citrate of iron, previously dissolved in 2 oz. water: filter. Each fluid ounce contains: fresh beef, 1 oz.; citrate of iron, 4 grains. Dose—one tablespoonful.

*Nutritive Wine.* Liebig's Extract of Beef and Wine.—Prepared same as above, omitting the citrate of iron.

*Elixir Aromatic.*—℞ Cort. aurantii 4 drs.; sem. coriand. 2 drs.; sem. angelicæ 2½ drs.; Cocci cacti 1 dr.; Spts. vini deod. 12 oz.; Aquæ 10 oz.; glycerinæ 5 oz.; Syrupi 5 oz.; Percolate 2 pints. A pleasant vehicle for administering nauseous remedies.

*Elixir Val.-Ammonia.*—℞ Ammonia valerianat. 96 gr.; fl. ext. vanil. tinct. cardam. comp. 3½ oz.; tinct. xanthoxyl. 2 drs.; syr. aurantii cort. 6 drs.; aquæ 4 oz.—Dissolve the valerianate of ammonia in the water, and add the other ingredients, previously mixed. Two grains val.-ammon. to each drachm.

## THE CHOLERA.

A SHIP has arrived at Hartlepool from the Baltic ports with two cases of Asiatic cholera on board. One patient died in a few hours; the other has been removed to a cholera hospital.

THE fatal cases of cholera during the week at Königsberg ending the 17th inst. exceeded all previous returns. Over 300 deaths occurred, the usual proportion of 50 to 60 per cent. of deaths having risen to 70 to 80 per cent.

ACCORDING to the latest official returns from Berlin, September 19, the number of individuals attacked by cholera in the Baltic Provinces amounted to 2,517 civilians up to the 10th inst., and 84 soldiers. Of these, 1,273 died, 620 recovered, and 708 remained under treatment.

A NOTICE appears in the *London Gazette* of Tuesday, stating that as the cholera now prevailing in Russia may be introduced into the ports of Europe, the masters and owners of vessels despatched from English ports must be provided with a bill of health, *visé* by the French consul, if they wish to avoid being subject to a quarantine of observation.

THE deaths from diarrhoea in London, which had been 487, 353, and 293, in the three previous weeks, further declined to 268 last week; these, however, exceeded by 149 the corrected average number in the corresponding week of the last ten years. Of the 268 last week no less than 244 were of infants under two years of age, and 13 of persons aged

sixty years and upwards. The deaths referred to cholera and choleraic diarrhoea, which had ranged between 40 and 20 in the four previous weeks, declined to 15 last week, only 5 being adult cases; of these 4 were certified as choleraic diarrhoea and 1 as English cholera.

Up to the 15th instant there had been no cases of cholera in Vienna; and it is hoped (says the *Wien. Med. Presse*) that the recent change of temperature will remove all danger of the occurrence of the disease for this year at least. Our Vienna contemporaries urge continued energy in carrying out within the city the sanitary measures agreed on some weeks ago (see *BRITISH MEDICAL JOURNAL*, September 2nd). It would seem that in Vienna itself there is some laxity; while in some at least of the suburbs active preparations to meet the disease are being carried on. In Sechshaus, for instance, the suburb is parcelled out into sections, to each of which a committee and physician are appointed for the purpose of making house-to-house visitations, remedying sanitary defects, and ordering the cleansing and disinfection of the sewerage. For the latter purpose, phenate of lime is the agent mostly used. The *statthalter*, Baron von Weber, is specially mentioned as being most energetic in the organisation and carrying out of sanitary measures.

## ASSOCIATION INTELLIGENCE.

### SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEETINGS.

THE next meeting is appointed to be held at Rochester (at St. Bartholomew's Hospital), on Tuesday, September 26th, at 3.30 P.M.; Dr. BURNS in the Chair.

Papers on clinical subjects by A. W. Nankivell, Esq.; by J. H. Lyddon, Esq.; and by Dr. Bell, are promised.

Dinner will be provided at the Bull Hotel at 5.30.

FREDERICK JAMES BROWN, M.D., *Honorary Secretary*.

Rochester, September 11th, 1871.

### EAST YORK AND NORTH LINCOLN BRANCH.

THE half-yearly meeting of the above Branch will be held at the George Hotel, Barton-on-Humber, on Thursday, September 28th, 1871, at half-past three o'clock precisely.

The following papers are promised:—Variola Hæmorrhagica; by G. F. Elliott, M.D.—Injury to Eye from Gunpowder Explosion; and Two Surgical Cases; by W. H. Sissons, Esq.—A Case of Abscess of the Lung; by J. B. Moxon, Esq.

The dinner will be provided at five o'clock. Tickets for dinner and dessert, 5s. 6d. each.

Members of the profession are invited to attend both the meeting and the dinner.

Gentlemen intending to dine, are requested to inform the Secretary on or before the 25th instant.

ROBERT H. B. NICHOLSON, *Honorary Secretary*.

21, Albion Street, Hull, September 1871.

### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEDICAL MEETINGS.

A MEETING of the members of the above District will be held at the Castle Hotel, Hastings, on Friday, the 29th instant, at 2.30 P.M. (not on Wednesday, as hitherto notified); the Chairman to be chosen at the time.

Dinner at 4 o'clock. Charge 5s., not including wine.

All members of the South Eastern Branch are entitled to attend, and to introduce friends.

Such as propose to stay to dinner, will much facilitate the arrangements by informing me on the previous day.

G. F. HODGKINS, *Hon. Sec. to the South Eastern Branch*.

52, Montpellier Road, Brighton, Sept. 20th, 1871.

### WEST SOMERSET BRANCH.

THE autumnal meeting of the above Branch will be held at the Railway Hotel, Taunton, on Tuesday, October 3rd, at 5 P.M. Dinner on the table at 5.15 punctually. Tickets 3s. 6d. each, exclusive of wine and waiters.

The following resolution was passed at the annual meeting:—"That with a view to obtaining from members of the Branch their opinion, and to this extent, authority on especial points of interest, a notice be sent to each member, at least one month before a general meeting of

the Branch (a question on a medical or allied subject to be proposed by the Council, on which at the said meeting each member will be expected to express his opinion; but having regard to the number of opinions it is sought to elicit, no argument in supporting an opinion shall exceed five minutes in delivery, whether read by the writer, or deputed, or spoken extemporaneously.)"

The following question has been settled by the Council as the one on which opinions should be now asked:—"Does the application of Carbolic Acid favour the healing of wounds?"

Gentlemen intending to be present at the dinner, or to read papers afterwards, are requested to give notice to the undersigned, so that he may make the necessary arrangements.

W. M. KELLY, M.D., *Honorary Secretary*.

Taunton, September 11th, 1871.

### SOUTH MIDLAND BRANCH.

THE next meeting of the above Branch will be held at the Town Hall, Wellingborough, on Tuesday, October 10th, at 2 P.M.

Gentlemen who intend to read papers or cases, are requested to forward the titles of the same forthwith.

J. M. BRYAN, M.D. } *Honorary Secretaries*.  
W. M. MOXON. }

Northampton, September 11th, 1871.

## CORRESPONDENCE.

### SANITARY AFFAIRS IN DUBLIN.

SIR,—As examples of injuries from sensational sanitary letters in newspapers, let me mention two statements from Friday's Dublin papers.

1. A "Commissioner" sent to accompany Dr. Grimshaw through the worst parts of the city, reports:—"Farther on in the Coombe we pass by the old Coombe Lying-in Hospital, which has just been abandoned. Though not exactly connected with my special task, I cannot help turning aside to mention a ghastly fact connected with this grimy-looking building. It is one of the oldest houses in Dublin, having been at one time the residence of the Earls of Meath. From the confined nature of the rooms and their long use as lying-in wards, they became saturated with the subtle poison of that dreaded disease—puerperal fever. The result was that the patients were decimated by this terrible scourge; and yet it is only the other day the plague-house was abandoned." Dr. Ringland has proved that the eight statements of which the above consists are all untrue.

2. A Poor-law Guardian is reported to have said that there had been last week a case of cholera on board a Russian vessel in the Liffey, and that Dr. Harty, County Coroner, had been sent to the ship by the Port and Docks Board. The man did not die. No item of this is true. No such case occurred; the County Coroner is not a medical man; he could not hold an inquest in the city, nor anywhere on a living man; and, lastly, the Port and Docks Board do not act in such cases.

Newspapers in dull times readily publish such statements, which frighten the public and throw discredit on the profession.

I am, etc., E. D. M.

### POOR-LAW MEDICAL OFFICERS AND HEALTH-OFFICERS.

SIR,—As a Poor-law medical officer, I must take exception to that part of Dr. A. P. Stewart's address in the *JOURNAL* of August 26th, where he says "The proposal to constitute the Poor-law medical officers throughout England and Wales officers of health is most objectionable. A more fatal gift to the Poor-law medical officers in their own interest and that of the public could not be made." I fail to see anything objectionable in the proposal, or fatal to our own interest or that of the public. On the other hand, I, in common, I believe, with every other medical officer, look upon the proposal (if carried out) as a means of improving both our *status* and incomes; and I think you will admit that we should be the best judges of our own interests.

I submit that the very nature of the duties we are every day called on to perform especially fits us for officers of health, as in our visits to the hovels of the poor we are brought face to face with those very conditions which I presume it is the duty of a medical officer of health to remedy—such as overcrowding, filth, bad ventilation, bad drainage, etc.

If these few remarks should be the means of drawing the attention of such gentlemen as Dr. Rogers and other Poor-law medical reformers to this subject, my object will be gained.

I am, etc., S. GOURLEY, M.D.

## OBITUARY.

WILLIAM NISBET, L.F.P.S. Glasgow, EGREMONT, CHESHIRE.

MR. NISBET died at Egremont on September 12th, aged 63, after having practised as a surgeon for nearly forty years in the parish of Wallasea. He was born in Paisley in 1808, and received his diploma from the Faculty of Physicians and Surgeons of Glasgow in the year 1827. He was then for a time in the service of the Honourable East India Company, and made two voyages to India in medical charge of troops. In 1833, he settled in practice in Wallasea, on the shore of the Mersey, opposite Liverpool, and remained there until his death. He had much openness of character and activity of mind. Mr. Nisbet had made for himself a lasting place of honour in the memories of all who knew him. He was unable to take food during the last weeks of his life, but there was no suffering. The necropsy showed the cause of death to have been cancer of the liver.

JOSEPH BIRT, M.B.

WE have to lament the early death of Mr. Joseph Birt, M.B., which occurred recently at his father's house at Leamington. His medical education was conducted at Sydenham College, Birmingham, where he was a distinguished pupil. Having passed the College of Surgeons and the Hall, he graduated with honours at the University of London, and was shortly afterwards elected House-Surgeon to the Stourbridge Dispensary, where the kindness of his manners and the assiduity with which he discharged his duties gained him the respect and regard of all with whom he came into contact. But it is not merely on account of his personal qualities and domestic worth that special notice is here recorded. In him the medical profession and the community at large have, there is reason to believe, sustained a real loss. Mr. Birt was devoted to his profession, both as a science and a practical art, in no ordinary degree; and as his abilities were much above the average, a distinguished career for him was confidently anticipated by all who had opportunities of judging of his talents. In his case there is reason to fear that

Science self-destructed her favourite son, and that his unremitting studies and zeal in the pursuit of professional knowledge, acting on a frame not habitually strong, contributed to his end, if not by directly inducing disease, at any rate by rendering his constitution less fit to resist its attacks.

JOHN WILLIAM IRVINE, M.D.

DR. IRVINE was the eldest son of Dr. James Pearson Irvine, who for a quarter of a century practised his profession in Lancaster. He was educated in the Royal Grammar School, Lancaster, and afterwards at the University of Glasgow, where his distinguished career in anatomy especially led to his appointment as Curator of the Leeds School of Medicine, at which place he finished his medical studies. He obtained his diplomas of L.R.C.S. Edin. and L.S.A. Lond. in 1859; and in 1862 became a Doctor of Medicine at St. Andrew's, passing his examination with high honours. His success in Liverpool, where he commenced practice, was rapid. He was at once appointed Honorary Surgeon to the Liverpool Caledonian Schools, and subsequently Honorary Surgeon to the Liverpool dispensaries. In 1864, he was elected Visiting Surgeon to the West Derby Union Hospital. All these appointments he held up to the time of his death. He was also an Assistant-Surgeon to the First Lancashire Rifle Volunteers. By gentlemanly bearing and scholarly attainments, Dr. Irvine had won the confidence of all who knew him, and had gained a promising position. With a kind word and a willing ear for all, he won from suffering humanity a love which is better than any stone man can raise over the grave, and left on the hearts of his fellows a better epitaph than pen can write. There are none who knew him who will not truly regret his untimely death. Dr. Irvine contributed to the medical papers essays on Fever in Liverpool, and on Resection of the Clavicle, with Formation of the Entire Bone. At the time when his illness overtook him, he was engaged on a paper for the *Liverpool Medical and Surgical Reports* on Amputation at the Hip-joint, that paper being the result of three successful hip-joint amputations after failure of resection of the knee-joint and disease of the femur.

Last spring, Dr. Irvine suffered from relapsing fever, the attack having been probably favoured by his unremitting labours in the wards of the West Derby Hospital during the late fever and small-pox epidemics. He never thoroughly recovered his strength, though he still supervised

the wards of his hospital with but short intermissions. In the beginning of August, by the strong advice of his medical friends, he was induced to undertake a voyage to Canada, on board the steamship *Germany*. He suffered on the second day from severe sickness, which prostrated him so much that, on the fifth day after leaving Liverpool, he died quietly and painlessly of exhaustion, at the early age of 33.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, September 14th, 1871.

Popham, Francis William Home, Gowler, South Australia  
Thomas, John Howell, Carmarthen

The following gentleman also on the same day passed his first professional examination.

Meredith, William Henry, Queen's Hospital, Birmingham

## MEDICAL VACANCIES.

The following vacancies are announced:—

**BIRMINGHAM LYING-IN CHARITY**—Two Honorary Surgeons.  
**CHARING CROSS HOSPITAL**—Assistant Physician.  
**CULROSS, Perthshire**—Parochial Medical Officer.  
**DUMBARTON**—Surgeon to the Prison.  
**GAINSBOROUGH DISPENSARY**—House-Surgeon.  
**GLANFORD BRIGG UNION, Lincolnshire**—Medical Officer and Public Vaccinator for the Messingham District.  
**GREAT WESTERN RAILWAY**—Surgeon for the Leamington District.  
**GREENWICH UNION**—Dispenser.  
**GUEST HOSPITAL, Dudley**—Resident Medical Officer.  
**HAWARDEN UNION, Flintshire**—Medical Officer for District No. 2.  
**KENT AND CANTERBURY HOSPITAL**—Assistant House Surgeon and Dispenser.  
**LIVERPOOL INFIRMARY FOR CHILDREN**—Honorary Assistant Medical Officer.  
**MANCHESTER, Township of**—Dispenser at the Male Infirmary at the Workhouse at Crumpsall.  
**MAGHERAFELT UNION, co. Londonderry**—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Bellaghy Dispensary District.  
**MANCHESTER ROYAL INFIRMARY**—Physician's Assistant.  
**MAYO INFIRMARY**—Surgeon.  
**MEDICAL AID ASSOCIATION, Bradford District** of the Manchester Unity of Odd Fellows—Surgeon.  
**MIDDLESEX HOSPITAL**—Assistant Surgeon; Resident Physician's Assistant.  
**NARBERTH UNION, Pembrokeshire**—Medical Officer and Public Vaccinator for District No. 3.  
**NORTH DISPENSARY, Liverpool**—Honorary Medical Officer.  
**NORTHERN HOSPITAL, Liverpool**—Physician.  
**OAKHAM UNION, Rutlandshire**—Medical Officer for the Empingham District.  
**ORSETT UNION, Essex**—Medical Officer for the Grays District.  
**PEMBROKE UNION**—Medical Officer for District No. 5.  
**QUEEN ADELAIDE DISPENSARY, Bethnal Green**—House-Surgeon.  
**STOCKPORT INFIRMARY**—House-Surgeon.  
**TENTERDEN UNION, Kent**—Medical Officer for the Halden District.  
**UNST, Shetland, Parish of**—Medical Officer.  
**WARMINSTER UNION, Wilts**—Medical Officers and Public Vaccinators for the Corsley and Warminster Districts and the Workhouse.  
**WARNEFORD HOSPITAL, Leamington**—Surgeon.  
**WARRINGTON DISPENSARY**—Resident Surgeon; Apothecary.  
**WESTERN GENERAL DISPENSARY, Marylebone Road**—Resident Surgeon and Apothecary.  
**WESTMINSTER HOSPITAL**—House-Physician.  
**WHITCHURCH UNION, Southamptonshire**—Medical Officer for the Overton District.  
**WIMBORNE AND CRANBORNE UNION, Dorset**—Medical Officer for District No. 2 and the Workhouse.  
**WORKSOP DISPENSARY**—Resident Surgeon.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.*

### BIRTH.

**DUCKWORTH.**—On September 21st, at 11, Grafton Street, Bond Street, the wife of \*Dyce Duckworth, M.D., of a daughter.

### DEATHS.

**BALL, John, Esq., Surgeon, at Walker Street, Liverpool, aged 88, on August 26th.**  
**CUTCLIFFE, Charles Elworthy, Esq., Surgeon, at Silvertown, Devon, aged 59, on September 10th.**  
**MITTON, Michael John, Esq., Surgeon, at Wildbad, North Germany, aged 31, on September 4th.**  
**\*NEWBOLD, Edward, Esq., Surgeon, of Macclesfield, on Sept. 8th, at Worthing.**  
**PHILLIPS.**—On September 13th, Margaret Anne, the infant daughter of \*T. R. Phillips, Esq., Surgeon, Treorchy, Pontypridd.

**THE "DR. HATTON" LIFE-BOAT.**—A new life-boat, bearing the above name, has been given to New Romney, with its equipments and boat-house, at a cost of £680, by the widow of Dr. John Hatton, formerly of Manchester.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.

**WEDNESDAY** .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY** ... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.

**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY** ... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

A MEMBER can procure information respecting the Jacksonian Prize Essay for this year, from Mr. T. M. Stone, of the Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.

W. S. (Bristol) will observe that the advertisement leaves the post open to all professions.

## CORONERS AND MEDICAL WITNESSES.

SIR,—A man was found dead in a river. A gamekeeper was found dead in his preserves, with shots through his head. A man was run over, and died next day. In all these cases, reports were held by a neighbouring county coroner, but medical evidence was ignored, the surgeon who had attended not even being notified of the inquests. Is this the intention of the Legislature or "Crown's 'quest' law"? I am, etc.; ENQUIRER.

Faversham, September 1871.

\*. \* It does not accord with either.

## THE INQUEST AT BATH.

DR. MEERES' letter arrived last week on Friday, and therefore after publication of the JOURNAL. We had, however, already taken the view which it suggests. We cannot see that any blame whatever attaches to Dr. Meeres. The sad occurrence was one which might well have happened to the most eminent and skilful of practitioners. He adopted a well known and much used application. An especial constitutional susceptibility appears to have existed on the part of his little patient, which could not be foreseen. Equally sad accidents sometimes follow the application of a blower. We are glad to see that the medical press generally has taken the same view of the facts; and Dr. Tilbury Fox has shown a creditable readiness in personally assuming the share of responsibility which falls to him as having recommended the application in his work.

## DETENTION OF CORPORATIONS.

SIR,—I have read Mr. Benson Baker's letters respecting the sanitary state of Dublin with great interest. His ideas are so novel, that the writer must have come from Laputa. He evidently supposes that the duty of the Corporation is to attend to the cleansing of the city and the health of its inhabitants. It is no such thing. As a gentleman is elected to be a member of that august body solely on account of his political attainments, so it is his duty to devote himself to politics. Unless, therefore, Mr. Baker can prove his complaint to involve a seditious-political question, it is not a proper subject for consideration. I am, etc.; FREEMAN.

## UMBILICAL ENDOCHORD IN AN INFANT.

SIR,—A child, about eighteen months old, has a small pea-like excrescence at its navel, which is ulcerated to a small extent at its summit, and from which exudes frequently a drop or two of blood. There seems to be no pain caused, as the child has frequently allowed it to be cauterized, touched with the strong solution of perchloride of iron, etc.; and when the system seems to be much affected. The child thrives, and has done so since its birth, from which time the mother states that the bleeding has gone on. Some treatment has been tried since it came under my care some months ago. I find, however, that it has improved most under the continued use of perchloride of iron (Perrioli's), the part being touched each morning, when required, with the strong solution of perchloride of iron. When this plan is persevered with, there probably is no discharge for three weeks or a month at a time. Just as soon as it is given up, the scab falls off, or becomes removed, and again there is a return of the old symptoms. As the case presents some difficulties, I shall be obliged if you or some of your readers will kindly instruct me how to act in the matter. The child is of rather stunted appearance; its father is decidedly nervous; the mother is healthy; and there is no history of hæmorrhagic diathesis. I am, etc.; J. I. R. E., M.D.

September 18th, 1871.

J. I. R. E., M.D.

NOTICE TO ADVERTISERS.—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

DR. GREENE (London) will, we believe, be correct in giving credit to the gentleman mentioned in his letter for the best motives and a pure desire for the public good.

DR. EDMUNDS complains that, the whole context of his speech being omitted, the observations last quoted are not sufficiently qualified in the quotation. Reading his whole speech, we do not, however, appreciate the point of the complaint. He states, by way of explanation:

"I was unexpectedly compelled to travel over the ground I did by the complaints of a reverend gentleman who preceded me, and bitterly referred to his experience of reclaimed drunkards who had been induced again to take intoxicants by their medical advisers, and had, as a direct consequence of that advice, relapsed into drunkenness and ruin. That complaint was omitted from the newspaper reports, as also was much qualifying matter that accompanied my own remarks. Doubtless, on the spur of the moment, I spoke warmly; and especially so, as I had just been disgusted by reading the twaddle about drink and tea that had been emitted by gentlemen supposed to represent the British Medical Association on an important occasion at Plymouth."

Dr. Edmunds's disgust appears to have led him to employ violent language against the profession, which, no doubt, he regrets, and which he might advisedly retract.

## DAMAGES IN RAILWAY CASES.

G. C. C. asks: "In the case of damages obtained by a patient against a railway company, does the medical man receive his account direct from the company, or through the patient? That is to say: Has he to get it by legal means, if not paid?"

\*. \* The question is rather legal than medical; but the claim is evidently upon the patient. He receives his damages on the faith that he owes a stated sum to his doctor, which he either has paid or is about to pay; and that is included in the sum granted by the verdict. The claim of the doctor is, however, equally valid upon the patient, whether the latter is entitled to and receives compensation or not.

## DISPUTED MIDWIFERY FEES.

SIR,—I notice in our JOURNAL a question from "A Member" as to "Disputed Midwifery Fees." I have had two cases in which my fee was refused, when I took proceedings and recovered the fee with all legal costs. The proceedings were taken in the first case in the County Court at Gooles; in the other, in the County Court at Malton—both in Yorkshire. In both cases judgment was given for me, on the ground that my fee was due to me from the moment that I was engaged, having held myself in readiness to attend; that, in fact, "it was a retainer." The circumstances of the two cases were rather different. In the first I was engaged to attend, they did not send for me, moved from the place, and sent for some one else rather nearer. In the second I was not engaged, but was sent for; I started in my carriage, but was met about a quarter of a mile from the village, saying I need not go, they had got some one else. I demanded my fee, and was refused. The judge, however, ordered payment, with costs, on the same general rule that the order to attend was a "retainer", that my not attending was not my fault, and that therefore I was entitled to my fee.

I am, etc.; R. GILLARD, M.R.C.S. Eng.

60, Clapham Road, S.W., September 15th, 1871.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, Sept. 16th; The New York Medical Record, Sept. 9th; The Boston Medical and Surgical Journal, Sept. 9th; The Madras Mail, July 8th; The Shield, Sept. 16th; The Philadelphia Medical Times, July 31st; The Philadelphia Medical Independent, Sept. and; The Birmingham Morning News, Sept. 15th; The Lancashire Guardian, Sept. 9th; The Glasgow Daily Herald, Sept. 8th; The Carlisle Post, Sept. 9th; The Devizes and Wiltshire Gazette, Sept. 7th; The Dumbarton Herald and County Advertiser, Sept. 14th; etc.

COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. C. Handfield Jones, London; Mr. G. Elder, Nottingham; Dr. Patrick Nicol, Bradford; Dr. T. Beatty, Dublin; Mr. A. H. Hunt, Romford; Mr. Wm. J. Square, Plymouth; Dr. Meeres, Melksham; Dr. J. Russell Reynolds, London; Mr. James Haworth, Filey, Yorkshire; Dr. R. W. Foss, Stockton-on-Tees; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; M.D.; Dr. Henry Browne, Manchester; Dr. James Russell, Birmingham; Dr. Edmunds, London; Mr. F. Le Gros Clark, London; Dr. Robert Barnes, London; Dr. Needham, York; Mr. Lara, London; Our Dublin Correspondent; Dr. Nicol, Bradford; Mr. Benson Baker, London; Our Edinburgh Correspondent; Mr. John Calder, Liverpool; Dr. Wm. R. E. Smart, Penzance; Dr. G. H. Philipson, Newcastle-upon-Tyne; Dr. Wahlteuch, Manchester; Dr. H. Cripps Lawrence, London; Dr. C. Kidd, London; Mr. J. T. # CLINICAL LECTURE ON HYPERÆSTHESIA.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.,  
Physician to St. Mary's Hospital.

BESIDES the classical disorders of the nervous system, which well instructed students like you are supposed to know all about—such maladies, for instance, as epilepsy and tetanus—there are a great many forms and varieties of morbid action which are less recognised and described, and scarcely find a place in a regular nomenclature, with which yet it is very desirable for you to be acquainted. Many of these belong to that debatable ground where it is difficult to decide whether we have to do with diseases or with symptoms. I shall now proceed to notice sundry instances of one very common kind of morbid action, as it manifests itself in different localities; and conclude with some remarks on its nature, relations, and treatment.

1. In the *cutaneous surface* we very often meet with a condition which betrays itself by no objective change yet discovered, but solely by an abnormal sensitiveness. The tactile faculty of the skin is not really increased; it is not a more efficient organ of touch than it was before, but quite the reverse, as its nerves are incapable of tolerating the necessary contact with bodies presented to them. Such a condition is conveniently termed hyperæsthesia; and this name I shall continue to use in what I have further to say about it. This state of hyperæsthesia is met with very frequently in sufferers of the quasi-hysterical class, both male and female. One poor fellow assured me that his skin had been so sensitive that he could not bear the least touch anywhere; the pressure of a stethoscope in auscultation was intolerable; and the touch of a crinoline-hoop against his leg in a railway-carriage caused him terrible pain. These complaints were made quite gravely; and though we can hardly avoid smiling at them, yet we must admit that to the sufferer himself such a state of things was no joke. Think what you would endure yourselves, if all ordinary contact were a cause of continual pain. The reality of such suffering is materially confirmed by the fact that, in some cases of structural disease of the cord, certain parts of the cutaneous surface manifest intense reflex excitability, though ordinary sensibility is much impaired. In a most workmanlike report in the *Transactions of the Clinical Society*, vol. i, p. 102, on a case of locomotor ataxy, it is mentioned that an area of skin on the outer side of the right leg, about two inches and a half square, was, and had been for about two years, in a condition of extreme sensitivity to impressions capable of exciting reflex movements—such that the patient had frequently been thrown into convulsions, and had dropped down in the street, from the mere brushing of a woman's dress against this part. Even when he touched this spot himself, either with his hand or his trousers, whilst dressing, slighter convulsive movements often took place. At these times he felt an odd kind of sensation in the part, which then diffused itself rapidly throughout the body. In such hyperæsthesia as this the sensorium is but little concerned; but there is evidently no improbability that the cerebrum might be the seat of such disorder, as well as the cord. In fact, this is actually the case in many instances of arachnitis. If you object, that I am now speaking of coarse structural lesions, this will not apply to the case of rickets, where the nervous centres are often exempt from evident lesion, and yet the general tenderness is such that the child cries if he be but touched.

The hyperæsthesia which affects the region of the spine, or, more exactly, the line of the spinous processes, needs to be somewhat specially noticed, because it has been much dwelt on, and is often accepted as a sign (with others) of meningitis or myelitis. Brown-Séquard speaks decidedly on this point; he says that "it is almost always found that pressure upon the spinous process of the vertebræ (sometimes even a slight one), when made at the upper limit of the inflammation, causes an acute pain" (*Lancet*, July 14th, 1860). Dr. Radcliffe, on the other hand, is inclined to the view that this pain is mostly absent, at any rate, in uncomplicated myelitis. My own experience leads me to look for it as a nearly constant symptom, but not in that degree of acuteness which characterises the neurotic disorder. This, at any rate, is certain: that pain in the back *per se* is no evidence whatever of inflammation being present in any of the component structures, any more than headache is of the cranium and its contents being so affected; and, indeed, the two dyæsthesiæ are in many respects homologous. Spinal hyperæsthesia extends sometimes over the skin on one side, and

not at all on the other; sometimes light pressure is painful, and firm relieves; sometimes the latter is the worse. In some cases, I believe, the bones are involved in the neuralgia, without being at all inflamed.

2. The *lingual and buccal mucous membranes* are sometimes the seat of extreme and most distressing hyperæsthesia. The affected parts may appear quite natural, or at most there may be undue redness and insufficient development of epithelium, giving a "beef-steak" appearance, but not at all more than I have often seen in patients who were quite free from this hyperæsthesia. The following case is a good example of this happily infrequent disorder. Mrs. C., aged 73, was seen August 28th, 1866. She had been suffering the last five weeks with her mouth, which was so tender that she could bear nothing in the way of food but lukewarm milk and sopped bread. Cold things gave her pain, as well as hot. The buccal membrane was very red, especially that of the lower lip. The whole surface, including that of the tongue, was extremely tender; but I saw nowhere any breach of surface, nor anything resembling an ulcer. There were certainly some superficial fissures on the dorsum, but they were no more than often exist without causing any suffering, and they did not appear to involve the corium. The tongue was perfectly clean and moist. Pressure on the mucous membrane did not render a spot pale even for an instant after its removal. The bowels were regular; pulse 84, of good force. The appetite was very good, but she felt quite exhausted from being unable to take food. She got very little sleep, from the distress caused by her mouth. She had suffered much from rheumatism, and felt the changes of the weather very much. My notes extend over more than four months, and show scarce any change to have occurred during the whole of that time; and I am tolerably certain that she continued to suffer in the same way, though less severely, to the close of her life, or till about April 1869. She constantly kept a piece of soft rag in her mouth, which afforded her some solace. On one occasion, I took the temperature of her mouth, and found it as high as 100.4 deg. F. The membrane of the buccal cavity always presented the same appearance of considerable hyperæmia. At one time, a little eczematoid eruption appeared at the margin of the lips, but it never extended internally. The suffering she endured must have been terrible; she described it as that caused by a burning fire, and declared she was enduring a living death. Her temperament was by no means excitable, and I do not think she exaggerated her griefs in the least. Many remedies were used; but none were of material efficacy, except a nightly opiate to procure sleep. The pathological condition was, I believe, one of neuralgia and hyperæsthesia, blended, as sometimes happens, with vasomotor paralysis, which latter produced the hyperæmia. The neurosis may have been of gouty origin.

3. The *throat* is liable to suffer with such disorder as we are considering, which it is important not to confound with common inflammatory, as the treatment required is materially different. The following case is an illustration. Mrs. N., a young-looking, recently married woman, was seen by me on September 8th. She had been suffering four days with swelling and neuralgia of the right side of the face. Her throat had become sore, so that she had much difficulty in swallowing. On the previous day, she could not get down a piece of sopped bread. There was some nausea and vomiting. The throat appeared normal, but with the laryngoscope I could see that the laryngeal membrane was much congested. Her voice, however, was not altered. She had soreness and tenderness at the sides of the neck, lower down on each side than the tonsils. She expectorated a little reddish mucus. She had some difficulty in getting her breath. Her sleep was disturbed; she woke up restless and feverish. She felt very weak. The urine appeared normal. I advised diligent steaming of the throat, sinapisms to the sides of the neck, fifteen grains of chloral at bedtime, and two grains of iodide of potassium and an ounce of effervescing mixture of citrate of potash three times a day. On the 9th, she slept two hours with the chloral, then woke in great uneasiness, and only dozed the rest of the night. At noon, I found her suffering much. The throat was very sore. She had not been relieved at all by the steaming; swallowing was very painful. She had much pain and tenderness in her neck; more, however, at the sides of the muscular part than in the larynx, which I could handle and move pretty freely. Her throat felt dry. Tongue coated; pulse 93. I ordered twenty grains of muriate of ammonia with ten minims of tincture of belladonna in water every four hours, hot fomentations to the neck, and aconite liniment. She also had immediately fifteen minims of chlorodyne, which gave her two hours' sleep; and at 9 P.M. I found her decidedly better, though she had a good deal of strange pain, hardly describable, on both sides of her head. The dose of chlorodyne was repeated at 10 P.M., and in the course of the night she had fifteen grains of chloral; but she was in high fever and delirium all night long. The room seemed whirling round; she felt as if she must get up and go out—as if she should fly.

She saw numbers of persons in the room, with great heads and little bodies; etc. At 9.30 A.M. on the 10th, when I saw her, her throat was much better; she took some toast. The catamenia had reappeared, which had stopped, after a day of normal continuance, on September 3rd. I ordered a drachm of tincture of cinchona flava four times a day. On the 11th, the throat was much better; she had still dysæsthesie about the head, and a large patch of urticarious erythema had appeared about each elbow. On the 12th, she was so well as to call on me and take her leave before setting out for the North. She had sweated copiously the preceding night, had a good deal of eruption on the legs and thighs, but made no complaint of her throat. The attendant neuralgia, the peculiar distress, the nocturnal delirium, the urticaria, and the "juvantia", all go to prove the neurotic character of the disorder, and that it was no common sore-throat, but one where the hyperæsthetic greatly predominated over the inflammatory element. The abrupt cessation of the catamenial flow may have had to do with the superposition of the disorder; but I think the most essential factor was influenza.

4. From the throat we descend to the *stomach*; and among the woes of this much-enduring organ we may well expect to find hyperæsthesia. In fact, this condition, in a greater or less degree, is of very frequent occurrence, and constitutes the chief disorder in those cases to which the term "irritative dyspepsia" is appropriate. In many of these, hyperæmia and catarrh exist also, but as secondary complications, rather than as primary maladies. The hyperæsthesia, I believe, as a paralytic neurosis, is prone to implicate the vaso-motor nerves, and impair the tone of arteries and the retentive power of capillaries. Such disorder may be simple—i.e., dependent on the state of the general nervous system; or it may depend on reflex irritation, as in pregnancy. In some of these states, pain is the more predominant symptom; in others, vomiting; in others, both are present in a marked degree. Andral relates a case where the tongue was natural, and the patient distressed by a very acute hunger; but the lightest food given to her was thrown up by vomiting, or, if it was retained, caused indescribable suffering. The hyperæsthesia was overcome by cold affusion and persevering administration of food. Here the disorder was simple; and such seems to be generally the case, though in some instances, as in the hyperæsthesia of pregnancy, the influence of reflex irritation is evident. Nitrate of silver is a really valuable remedy in cases where pain is distressing; and, as it need only be given for a short time, you run no risk of spoiling your patient's complexion. It may be seconded, however, or replaced, very frequently, by subcutaneous opiates. I have employed them myself with the best effects. Dr. Clifford Allbutt writes strongly in their praise. One of his cases was that of a merchant who regarded himself as a hopeless dyspeptic, dreaded his meals, and especially his nights. He was cured (at least for the time) by one-fifth of a grain of morphia subcutaneously at 3 P.M. and 10½ P.M., followed by rest, during ten days, with one-fourth of a grain at night only for ten days more. I prefer myself to make these injections at the epigastrium, but this is not necessary. When the hyperæsthesia expresses itself in immediate vomiting without severe pain, I have great faith in strychnia, administered in doses of one-twentieth of a grain in not more than half an ounce of water. Let me cite the following instance. A slight-made female, aged 22, married four months, subject to indigestion, and weakened by a miscarriage, was brought to me with severe sickness of ten days' duration, no food having been retained the last three. I gave her, in my room, one-twentieth of a grain of strychnia, and made her lie down. After she had retched a few times ineffectually, she became much better, "did not feel at all sick", and took successively four teaspoonfuls of milk before she left. I saw her again in ten days, when she was greatly better, had only been sick once, and was able to take chicken.

5. That the *tracheal and bronchial* mucous surface is liable to hyperæsthesia, cannot be doubted. There are coughs of the most vexatious and obstinate character, which are either unattended with *râles* or expectorations, or where these are out of all proportion insignificant to the severity of the cough. Some of them are of reflex origin, as in Graves's case, where the explosion of a tinea put an end to a most violent cough, that went on night and day, and resisted all remedies. Some are due to toxic matters in the blood, as is probably the case in pertussis, and in some cases of gout, where, as Graves says, the cough is dry, unrelenting, and often very obstinate. Some, again, are simple neuroses, as in the case related by Trousseau, of a young lady who was of an hysterical constitution, but was exempt from catamenial irregularity, and from other nerve-disorders, except a continued cough, which proved refractory to all remedies, but yielded immediately to change of air. The treatment which appears to me most rational and satisfactory in pertussis is that recommended by Dr. E. Smith, of producing and maintaining moderate narcosis by means of small doses of morphia;

and this is quite accordant with the view that the paroxysms depend upon a specific toxic hyperæsthesia. There is another form of bronchial hyperæsthesia with which it is very important for you to be acquainted—viz., that which occurs in certain instances of pneumonia, where after a time the respiration becomes inordinately frequent, perhaps 80 in the minute, without any corresponding increase in the pulmonary lesions or lividity of face. In these cases, the hurry of respiration is a mere neurosis, and yields to opium and a due amount of support.

7. The *heart* enjoys no exemption from hyperæsthesia. Cases are not at all rare where there is more or less præcordial uneasiness or pain, with rapid, vivid action of the heart, unduly forcible impulse against the chest-wall, and loud sharp sounds. The radial pulse may be small and weak, contrasting strongly with the apparently forcible efforts of the heart. Such diseases are often seen in young persons, and are sometimes mistaken for instances of cardiac hypertrophy; from which, however, you may easily distinguish them by observing that the dulness-area is not increased, and the apex-beat not lowered nor displaced to the left. Toxic agents, such as tea and tobacco, reflex irritations, as of the gastric mucous surface, and primary failure or disorder of nerve-force, may all be incriminated in different instances as efficient causes. In the latter group, it seems most probable that the nervous filaments distributed to the endocardium are unduly impressible, and, being thus over-stimulated by the moving blood, keep the muscular fibres in a state of rapid action. Anæmia, though a very common cause, is by no means necessarily present. In Da Costa's account of the curious cardiac malady frequent among American soldiers in the late war, he mentions, as symptoms, constantly recurring attacks of palpitation and pain, whose chief seat is near the apex of the heart, and combined very commonly with excessive cutaneous sensibility. In some of his cases, the disorder supervened on fatiguing marches; in others, it occurred after fevers or diarrhoea. He tells us in his recent paper (*American Journal of the American Sciences*, Jan. 1871), that digitalis or digitaline had more influence on the cardiac disorder than any other drug resorted to. Belladonna internally he also found a most efficient agent, particularly valuable in instances of irregular action. Aconite reduced the force of the heart, and lessened the tension of the pulse; it was most suited to cases of commencing hypertrophy. No special commendation is bestowed on other sedatives; and gelsemin, which is reputed to be a cardiac sedative, disappointed him much; for the most part, it had no effect at all. Morphia hypodermically relieved the cardiac pain almost invariably, and so did atropia; but the effect was only temporary. Tonics were often most excellent adjuncts to treatment, but availed little by themselves. Zinc and iron accomplished most. Da Costa's experience has convinced him that there is a real connexion between the functional disorder, cardiac irritability, and the organic one, cardiac hypertrophy; that, in fact, "the one grew out of the other." Dr. Walshe admitted the same connexion several years ago. I cannot refuse to admit the doctrine held by these high authorities; but my own experience would not lead me to rate this cause of hypertrophy highly. I am sure that a weak and irritable heart may simulate very much a condition of hypertrophy, and yet, under suitable treatment, subside into a condition apparently healthy. A belladonna plaster is a remedy that generally does good service, and is to be preferred, I think, in most cases, to the subcutaneous opiate, which, in two cases where I tried it, produced more syncope than was at all agreeable to witness. Dr. Clifford Allbutt, however, assures us that subcutaneous injection of morphia in small doses is very valuable in so-called irritable heart, whether this be due to weakness of the organ or instability of its nerves. The first dose administered in this way should not exceed one-tenth of a grain.

8. A sort of diarrhoea, which I have occasionally met with in elderly persons, seems to me attributable with much probability to hyperæsthesia of the *mucous lining of the rectum*. The feces appear natural enough in all respects; but the lower bowel is intolerant of their presence, and, in a fidgety petulant manner, insists on expelling them much more frequently than is at all convenient. Belladonna has appeared to me of some service in this condition of things, and still more, perhaps, cold sponging of the anus directly after defecation.

9. Nocturnal incontinence of urine is an instance of hyperæsthesia affecting the *bladder*, to which it may be sufficient to allude. Let me, however, add that recently Dr. Barclay has praised syrup of iodide of iron as unfailing in this disorder. Belladonna in gradually increasing doses, you know, is the most approved remedy; but there is no reason why both should not be employed. A tonic will sometimes quell hyperæsthesia better than a sedative. Hyperæsthesia of the *urethral lining* is a marked feature in many cases of spermatorrhœa, and its removal by means of repeated catheterisation is reputed beneficial.

10. Hyperæsthesia of the *testis* is a very distressing neurosis; it reacts very injuriously upon the mind, and has in several instances in-

duced sufferers to insist on the removal of the affected organ, which in three cases was found healthy by Sir A. Cooper. He considers it of centric origin; but it may be of reflex peripheral origin, as in the following case. A. C., aged 23, was admitted Nov. 13th, 1870. He was in good health until five days previously, when he was suddenly taken with pain in the left testis; it was severe, and the testes began to swell. In a day or two the right became painful also. These symptoms were succeeded by pain in the loins and head. The pain now affected him only when he stood up, or when the testes were pressed. There was very little swelling of either testis. He had some tenderness of the hypogastric region, and a good deal of straining at stool. He had no sleep at night. Temperature 103.5 deg.; pulse 80. He had thirst and anorexia. On the 15th, he experienced a kind of tearing sensation at both external abdominal rings, going down into the testes. On the 16th, the temperature was 97.2 deg.; pulse 60, weak. The bowels had not been open since admission. His extremities became very cold the previous night; and he then became very hot and burning, and afterwards perspired profusely. He could not stand without support; the room and everything appeared to turn round with him. His testes were small, soft, very tender when touched, and the pain shot up along the cords. The bowels were now well opened by castor-oil, and afterwards an opium suppository of one grain was introduced. The testes ceased to be painful about four hours after the bowels acted, before he had the suppository. On the 17th, they bore handling well; he was also less giddy, could walk, but not very steadily. He had no pain anywhere. He was now taking tincture of cinchona and carbonate of iron, and by the 23rd was getting quite well. The hyperæsthesia and pain of the testes in this instance were mainly dependent on the irritation caused by feces in the lower bowel; but the action of this cause was probably much promoted by the existence of influenza enfeebling the nervous system.

11. We should be disposed, *à priori*, to expect that an organ with such extensive and powerful sympathies as the uterus, would be prone to suffer from sensory disorder, and such appears to be the case. The affection originally termed "irritable uterus" by Dr. Gooch is regarded by him, Churchill, Mackenzie, Tilt, and Ferguson, as essentially a neurosis. The latter expressly says "the local changes have been the fluctuating, the nervous affection the constant, element". The tenderness is so great and constant that great suffering is experienced if the patient incautiously sit down upon a hard seat, or if coition be attempted. One of the seats of this neuralgic malady is the vagina itself, which is so exquisitely tender as to render intercourse intolerable. Here I think we cannot fail to recognise hyperæsthesia as the essential morbid element—at least if we accept the dictum of Dr. Ferguson above cited, confirmed as it is by Churchill's authority, to the effect that in the cases seen by him there was no ground whatever for the supposition of inflammatory action. Associated with hyperæsthesia, there may be, as we have before seen, more or less of hyperæmia and inflammatory congestion; but this is not in any degree the cause of the sensitiveness. Dr. Mackenzie's statement is of practical importance, that this neurosis may be of reflex origin, and dependent on gastro-intestinal irritation. In most cases, however, it seems to be primary, and to result from some cause of nerve-exhaustion, as great fatigue, acting no doubt on a weakly organised nervous system. The *relentissement* of this neurosis on the higher centres seems to be very pernicious; the natural emotions and faculties become miserably perverted, and all nobility of character is lost in absorbing selfishness. Sedatives, locally applied by pessary or enema, subcutaneous injections, and tonics, are our best pharmaceutical remedies; but change of scene and place, and a suitable climate, may be still more important.

12. Hyperæsthesia of the female breast, attended with more or less enlargement, is a well known phenomenon. It may suffice for me to have named it, and to cite Mr. Erichsen's authority for its not being unfrequently dependent on uterine irritation.

13. Hyperæsthesia of the joints is well known to surgeons since the publication of Sir B. Brodie's work on local hysterical affections, which I advise you all to read. The most constant symptom is morbid sensibility of the joints and adjacent parts, which is associated sometimes with more or less general tumefaction, apparently from a turgid state of the small vessels. I have known a condition of this kind, attended with sanguineous vomiting, yield to carbonate of iron, after an offer of amputation had been (fortunately) declined. I hope none of you will ever make such a *faux pas*.

14. As regards the nerves of special sense, I cannot doubt—taking first the optic—that, even putting aside the case of strumous ophthalmia, where it might be contended that the photophobia was dependent on irritation of the filaments of the fifth nerve distributed to the cornea, there is really such a disorder as retinal hyperæsthesia. Mr. Soelberg Wells states that in this affection there is intense photophobia, though

the eye is quite normal. There is often great ciliary neuralgia, the pain extending to the face and corresponding side of the head. One point which he mentions appears to me of especial interest—viz., that the peripheral portion of the retina is anæsthetic, while in the central vision is perfect and hypersensitive. This is very indicative of the true character of the disorder, of its affinity to paralysis. The causes are such as impair the general health or strain the retina; and the correct treatment is to rest and soothe and recreate nerve-power.

The auditory nerve also is liable to hyperæsthesia. Sir T. Watson mentions having observed this in a man moribund from cholera. Dr. Russell Reynolds affirms that hysterical girls do sometimes seem to hear through stone-walls. Intolerance of sound is an occasional symptom in the early period of meningitis, and is not unfrequent in nervous headache, and in azoturic sufferers. The only thing common to these various conditions is a lowered degree of vital power.

15. That the *cerebrum*—the great centre where impressions are commingled into perceptions—is liable to pass into a state closely analogous to that of a tertiary centre and sensory nerve when these are hyperæsthetic, seems to me not doubtful. Gooch mentions the case of a deranged lady, whose prominent belief was that her husband was unfaithful to her. The notion, so far from being unreasonable, was, he believes, true, and she had known it for many years without any unnatural disquietude, but now it engrossed all her thoughts; she neglected her ordinary pursuits, took a dislike to her friends, felt no interest about her children, and sat silent and motionless from morning to night. After continuing deranged several months she recovered, although she retained the same opinion. Gooch justly says her insanity consisted not in her ruling idea, but in its overwhelming influence over her feelings and conduct. A modern pathologist would probably express this by saying that her brain had become enfeebled and hyperæsthetic, and was, therefore, intolerant of the idea it had previously endured. The following occurrence is similar. A religious student, who was much harassed by petty scruples and fancies, and well aware of their pernicious effect, observed after a time that he was always more plagued by them while preparing for an examination; i.e., when his cerebral power was most exhausted. The essence of hypochondriasis seems to be a special hyperæsthesia to corporeal impressions emanating *ab interno*. How much the tyranny of these may depend on enfeeblement of the great centres, is shown by P. Frank's account of his own sufferings from the dread of aneurism, induced by mental exertion, and removed by recreation. This is much too large a subject for me to attempt to handle now: all I can do is to commend to your attention the notion of cerebral hyperæsthesia as essential to the due comprehension of many common phenomena.

How far the seat of the action giving rise to hyperæsthesia may be purely peripheral, is difficult to say. In the great majority of instances, some nervous centre is probably engaged; but some facts—such as the removal of severe neuralgia for some months after section of the nerve, and the cessation of suffering after amputation of the testis—incline me to believe that the morbid action may have its chief *locus* at the periphery, and that without any apparent structural change in the affected part.

*Pathological Change in Hyperæsthesia.*—You may be disposed to ask me what this is. I wish I could tell you; but our knowledge of this matter is very scanty. All that we can say is, that it is undoubtedly a condition of imperfect nutrition, inasmuch as it may be generated by deprivation of blood, by injuries to nerves, by miasms in the blood, by remote irritation—in short, by all sorts of things that are injurious. Some particulars under these heads deserve to be mentioned. Hyperæsthesia of the most intense kind is produced sometimes by obstruction of the arteries with fibrinous deposit. Dr. Fuller describes a case where the first symptom was acute pain, associated with such exquisite tenderness of the whole limb that the slightest touch caused intolerable suffering. The hyperæsthesia continued until mortification set in. At the necropsy, all the larger arterial trunks, from the iliacs downwards, were found blocked up by firm light-coloured coagula of long standing. No other cause existed for the hyperæsthesia in this case, except the deprivation of blood. In Dr. Waller's experiments on refrigeration of the ulnar nerve, the ultimate effect produced was anæsthesia in the course of the nerve, but this was preceded by hyperæsthesia. It can scarcely be thought that the latter was, under the circumstances, anything but the first stage of the former; and, therefore, the conclusion seems necessary that it implies not an exaltation, but a deterioration of vital power. Again, there is a case on record where, during the gradual recovery of the brachial plexus from an injury, the skin of the upper part of the arm possessed natural sensibility, another (probably the mid part) was morbidly sensible, while that immediately beyond was quite insensible. Here, again, the conclusion seems inevitable that hyper-

is implies a damaged state of nerve-tissue, though not so severe as that which exists in anæsthesia. Much other clinical observation is the same effect; the same morbid alteration of sensibility (cutaneous) is met with in typhus and typhoid fever, in influenza, in rickets, and in epidemic cerebro-spinal meningitis. On the other hand, there is not the least proof that real increase of functional energy renders an organ less tolerant of its natural stimuli: in fact, the evidence tends quite the other way. A vulture's eye, which can discern a carcass at an extraordinary distance, can easily endure the full blaze of tropical daylight, and is evidently altogether in a different condition from the eye of a photophobic invalid. Several similar instances might be cited; and, on the whole, the general truth of the view here taken seems to me established. In a recent lecture on Experimental Physiology in the *Lancet*, February 11th, 1871, Dr. Rutherford has noticed this point without explaining it. He says, "the curious point, is that a nerve whose nutrition is to some extent defective should discharge its energy more readily than one whose nutrition is perfect." In what respect defective nutrition changes the nerve-tissue, I have said we cannot tell; but we may, I think, exclude oedema; for Buhl affirms as the result of his observations of continued fever, that the presence of much fluid in the subarachnoid and ventricular spaces corresponds with stupor or unconsciousness. Patients dying of delirium tremens have commonly wet brains, and they die for the most part in stupor. However, if we adopt, as I am much inclined to do, Dr. McDonnell's theory of nervous action, the detection of some material change may not perhaps be the most important matter. He assumes that the various impressions are propagated by undulations, the wave-length of which varies, so that the same conductor may be able to transmit several impressions. Now, on this view, it might be that undulations of a certain length and rapidity produced normal sensation, those of a less extent gave rise to hyperæsthesia, while a still further reduction of the undulations caused pain, and their total arrest anæsthesia. This may seem the more probable, as there is undoubtedly a close connection between the three just-mentioned morbid states. They often occur together, acknowledge the same causes, and are removed by the same remedies. Another connection of hyperæsthesia is less frequent, but is extremely well marked in rickets, viz., that with vaso-motor paralysis. I use the latter term hypothetically, for the phenomena actually observed are hyperæsthesia of the cutaneous surface and profuse sweating. The latter, however, as I have argued elsewhere, seems to be distinctly traceable to defective contraction of vessels from a parietic state of their nerves; and if this be so, then the connection is as I have stated. Admitting this, it is difficult to see in the hyperæsthesia anything else than a species of paralysis very similar to that which affects the vaso-motor nerves, and which may itself depend on defective molecular movement.

Allied, however, as these morbid states are, there are differences between them, which are important as regards treatment; thus anæsthesia is more connected with prostration, and is more benefited by stimulants than hyperæsthesia is. The latter is sometimes intolerant of these, and yields better to remedies of the sedative class. Thus in a case of pain with anæsthesia, bark, ammonia, and wine suggest themselves; whereas if hyperæsthesia be in the ascendant, bromide of potassium or chloral, or subcutaneous opiates, seem more hopeful remedies. Yet we must not strain this rule, for it admits of numerous exceptions. Neither must we ever omit a careful inquiry into the cause of the hyperæsthesia, for the knowledge of this may be all important. It is idle to go on administering tonics or sedatives if a focus of irritation need to be removed, or if the disorder be dependent upon poisoned blood. Here is much room for the exercise of real diagnostic skill, not that which contents itself with affixing a name to a given case of disease.

**VACCINATION.**—Several persons were summoned on Monday at Dartington. In the cases of the Rev. T. H. Gordon, Messrs. G. S. Gibbs, T. B. Spence, Alexander Wheeler, and James Metcalfe, orders were made to have vaccination performed. The summons against Mr. M. Fooks was adjourned for two months. Mr. Spence refused compliance because three of his children had, he said, died from vaccination.

**BEQUESTS, DONATIONS, ETC.**—Mr. Richard Dixon, of Brighton, has bequeathed £200 to the Hospital for Diseases of the Chest, Victoria Park, £200 to the Asylum for Idiots, and £100 to the Royal Hospital for Insane, besides legacies to numerous non-medical charities.—Mr. William Lord, of Clapham Road, has bequeathed £200 to the Hospital for Consumption at Brompton, and £200 to the City of London Hospital for Diseases of the Chest.—Mr. William Peckover, of Wisbech, has given £200 to the Norfolk and Norwich Hospital.—The Queen's Hospital, Birmingham, has received £100 under the will of Mrs. Smart.—Mr. Giuseppe Nivani, of Brighton, jeweller, bequeathed £50 to the Sussex County Hospital, Brighton.—"A. B." has given £100 to the Salisbury Infirmary.

## SEWAGE-IRRIGATION CONSIDERED IN CONNECTION WITH PUBLIC HEALTH.\*

By WILLIAM HOPE, ESQ., V.C.

It was with great pleasure that I responded to the invitation of my friend, the President of this Section, to read a paper on this branch of the sewage question, as I have no doubt that in the discussion which follows I shall receive much instruction and assistance in the practical carrying out of a reform which, I venture to think, will do more for the public health of this country than almost any other which has yet been suggested; and this I feel no hesitation in saying, because, although a very ardent advocate for sewage-irrigation, I do not of course profess to be in any way its originator; but I should say that I have come here also from a sense of duty, because sewage irrigation, or sewage utilisation, in whatever form, is a problem which not only demands the co-operation of chemists, engineers, and agriculturists, but ought to receive both the assistance and the jealous supervision of those members of the medical profession who more especially devote their attention to questions of hygiene.

I do not propose on this occasion to trouble you with a long dissertation on sewage utilisation by means of irrigation as distinguished from all the other methods which have from time to time been suggested to effect the same end; but I may perhaps be permitted briefly to allude to the other methods suggested, because I feel sure that there are certain fundamental considerations involved, which have only to be mentioned in order that the other systems may be condemned by every student of hygiene.

All other systems of dealing with the sewage question may be classed under two heads. First, there are the suggestions similar to that of an indefatigable and most praiseworthy reverend gentleman, whose name must be familiar to you all—Mr. Moule—who proposes to deal solely with the solid excreta of human beings, together with that small portion of urine which can be simultaneously dealt with. I am aware that there are many persons enthusiastic enough to believe that the average British housemaid, or the average working man's wife, could be trained to carry out a duplicate system of slop-collection with two kinds of slop-pails—the one for the reception of urine only, and the other for the reception of dirty water only. Possibly when all the various branches of physical science which have been suggested by the different school-boards as *extra studies* shall have become *compulsory*, and shall have been taught for several generations, such subjects as we are about to discuss will be as well understood by Mary the housemaid, and Mrs. Hodge the ploughman's wife, as they are at present by the British Medical Association. But it is obvious that, until Professor Huxley and Mr. Ruskin shall have completed Mary's education and that of Mrs. Hodge, no system for the disposal of sewage ought to receive your sanction which does not make due allowance for the present imperfect intellectual development of the instruments through whose agency the system has to be carried into effect; and even when we, or rather when our great grand-children, shall be blessed with scientific housemaids, I doubt whether the British Medical Association of the future will even then be disposed to sanction any of the systems coming under this first head, because none of them make any attempt to deal with the vast, most noxious, and fever-producing refuse of other kinds coming from human habitations: I mean soap-suds from bedrooms and washhouses, slops from the washing of floors and passages, and kitchen-refuse, including the water in which fish and vegetables are boiled, waste vegetable and animal fibre, grease, etc. It is true that Mr. Moule talks about a small area of land for subterranean irrigation as an adjunct to his system for the disposal of this part of the sewage; but it is perhaps impossible to conceive anything much more thoroughly mischievous and thoroughly unscientific than such a suggestion. A very large area might perhaps lead to no actual mischief, if to no good; but a small area, intersected by porous pipes, through which the stuff has to percolate under pressure, is, looked at physically and chemically, simply a series of small elongated *leaking cesspools*, which would eventually silt up, and by which, until choked up, the subsoil would be kept continuously saturated with unoxidised solutions of animal and vegetable matter, containing all those vibrios, bacteria, and other suspicious organisms which Dr. Bastian believes to originate spontaneously in such a pabulum, which Dr. Crace

\* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

Calvert declares he has only succeeded in boiling to death at a temperature of 400 or 500 deg. Fahr., and which Sir W. Thomson would now have us believe rode over here from the tail of a comet on a red-hot meteoric stone. You are all familiar with Dr. Frankland's ingenious experiments with what he calls, very clearly, "intermittent downward filtration". You recollect how he showed that the effluent sewage, escaping from intermittent downward filtration, through six feet of soil, which had been thoroughly aerated, escaped in a completely oxidised condition, while that escaping from upward filtration came away—clarified, no doubt, to the naked eye, but still containing all the elements dangerous to human life—in an entirely unoxidised condition. Now Mr. Moule's leaking elongated cesspools would simply produce the same result as upward filtration, because the soil would necessarily be kept saturated, as it could not be drained, and the sewage would indeed enter it at a point where there is already a large diminution in the size of the air-spaces, owing to superincumbent weight, and where it would also be below most of the feeding rootlets of vegetation, although this would be to some slight extent counteracted by capillary attraction; therefore this subterranean irrigation would necessarily pollute any springs or wells that there might be within reach of the area of land operated upon, while the effect upon health of raising the level of water in the subsoil is so well known to the British Medical Association that I need not touch upon it here.

Now we come to the systems which may be classed under the second head; viz., those which attempt to deal with town-sewage when manufactured by all the usual appliances of water-closets, sinks, drains, and sewers, by means of some chemical or mechanical process, or of some process which my friends Dr. Letheby and Mr. Hawksley so strongly advocate and so firmly believe in, termed by them a "chemico-mechanical" process, which unfortunately has yet to be discovered. For this reason, namely, that it has yet to be discovered, I do not propose to touch upon the latter system at present; and I think that we may in this section of the British Medical Association speedily dismiss all the mechanical and all the chemical processes. No doubt, if some very perfect filter were discovered which would reduce the effluent water to the same physical state as that of freshly distilled water, it would probably be completely successful; because we have no reason to suppose that the nitrogen which would be present would be in itself unwholesome, whether it were present as nitric acid in nitrates or nitrites, or even as ammonia itself, excluding, as I assume would necessarily be the effect of such a theoretical filtration, *albumenoid ammonia*.

But no such filter at present exists, and it must be perfectly obvious to every practical man that it must for ever remain a physical impossibility to pass such enormous masses of sewage as we have to deal with in the case of London and other large towns, through a filter so theoretically perfect as I have supposed; and I am sure I need not argue here against the admission into rivers to be drunk by human beings at lower points on their course of matters containing *albumenoid ammonia*, and all the curious and little known organisms which the microscope reveals in such solutions as town-sewage. Then, as to the chemical processes which might be assumed to take up the matter where the mechanical processes leave it, there is not one of them which touches to any appreciable extent the ammonia in solution; and if we consider what an exceedingly attenuated solution of ammonia town-sewage is, containing only from two to three up to ten or a dozen parts of ammonia in 100,000, we must feel that to invent any chemical process for seizing this ammonia which could be practically worked in dealing with millions of gallons of sewage at a time, is an attempt to achieve what is necessarily impossible. It is like squaring the circle.

We must, therefore, necessarily fall back, along with every Royal Commission or Parliamentary Committee which has ever yet sat on the subject, on irrigation as the only means of dealing with the sewage question in all its bearings with a fair chance of success. I say "with a fair chance of success," because I am always perfectly ready to admit in argument that there may possibly be difficulties and dangers in sewage-irrigation, even when practised in the most perfect manner that it is possible to devise, which dangers have not yet been discovered or suggested. But as I do not believe that it is possible that no method of dealing with the sewage question can succeed at all, I should call for the most complete and unassailable proof before I admitted that any such dangers were necessarily part and parcel of sewage-irrigation.

Many persons, I know, and especially medical men, have, however, a strong antipathy to sewage-irrigation acquired from some one particular instance where they have seen it at work, and could see that dangers did palpably exist; but this only shows us how careful we should be in drawing general conclusions from particular instances. A physician is not an engineer; and although he cannot be blamed if he do not see how such dangers as I have alluded to, and which I shall hereafter touch upon more fully, can be avoided, yet I do blame him if he con-

demns sewage-irrigation in the abstract, because he happens to see that, as carried out in a particular place, it involves danger. Rather let him point out the danger and call upon the engineer to remedy it.

Now, one danger was suggested as possibly attendant upon sewage-irrigation, which was susceptible of absolute proof or absolute disproof; and as it was one which I myself readily admitted as a theoretical possibility, while entirely disbelieving in its actual existence, and as it one, moreover, which cannot fail to be peculiarly interesting to the members of the medical profession, I will take it first, although it is perhaps a little out of order. I mean the danger suggested by my friend Dr. Spencer Cobbold, F.R.S., of the possible communication of entozoic disease, both through vegetables grown by sewage and eaten raw, such as lettuces, celery, etc., and through oxen and sheep fed upon sewage-grown produce. It is an undeniable fact that a certain percentage of the inhabitants of every town suffer from various forms of entozoic disease; and it is a necessary consequence that the sewage of every town must contain a certain number of ova of various kinds of worms, even if we exclude the echinococcus of the dog and the other forms which do not inhabit human beings. To Dr. Cobbold it appeared a certainty that the spread of all these ova over the surface of land by irrigation would be the surest of all means for propagating entozoic disease. He therefore condemned sewage-irrigation. He was right to point out the danger, and to call upon the engineer to disprove its existence if he could; but I venture to think that he was somewhat hasty in coming to the conclusion that it really did exist.

Negative proof is, of course, always a very difficult thing to attain to; but this danger, if it exist at all on a properly laid out and properly managed sewage-farm, must exist to such an immense extent that there ought to be no difficulty in filling an ox in a short time with the larvae of the common tapeworm (*Tænia Solium*). So I sent over to my Romford farm a bullock bred by myself from sewage-fed parents (both of which I had saved from rinderpest by carbolic acid); and having shut him up, I fed him for twenty-two months continuously on sewage-grown produce exclusively, and very often upon refuse lettuces, outside cabbage-leaves, and the rakings of Italian rye-grass. During all this time, however, he was watered from the house-well instead of from the horse-pond.

On the 15th of July last, this animal was slaughtered, and carefully dissected and examined by Dr. Cobbold himself and Professor Corfield, Professor Marshall also being present during part of the time. This examination was conducted as a regular piece of business for the Committee of the British Association, and not at all in an amateur way, but thoroughly and exhaustively. The following is the report of Dr. Cobbold.

"Report to the British Association Committee on the Treatment and Utilisation of Sewage.—Your Committee having invited me to examine the carcass of an ox fed for two years past on sewage-grown grass, at Mr. Hope's Farm, near Romford, I have to report the perfect freedom of that animal from internal parasites of any kind. I attribute this marked negative result to the following circumstances. First, the animal did not graze on the farm, but was fed exclusively upon vegetable products cut and carried from the land. Secondly, the porous nature of the soil and subsoil alike would rapidly carry off the sewage, and thus ensure the passage of parasitic germs into the soil itself. Thirdly, I noticed on the irrigated portions of the farm a remarkable absence of those molluscan and insect forms of life which frequently play the part of intermediary bearers. Fourthly, the only molluscs I detected were examples of *succinea putris*. These were obtained from a small pit of water to which the sewage had no access; and when examined after death were not found to contain any cercarian larvae. Fifthly, the flaky vegetable tufts collected by me from the sides of the furrows occupied by sewage-currents, consisted chiefly of *batrachospermum moniliforme*, in the filaments of which were numerous active free nematodes, but no ova of any entozoon. Sixthly, the sewage had a strong smell of beer, suggesting the presence of sufficient alcohol to destroy the vitality of ordinary parasitic germs, though it was abundantly manifest that the free nematodes had suffered nothing in consequence. As some guarantee for the efficient manner in which the carcass of the ox was examined, I may mention that the superficial muscles, with their associated areolar and aponeurotic coverings, were particularly investigated; portions of certain muscles, such as the scaleni and sterno-maxillaris, being dissected through and through. All the viscera were likewise scrutinised, especially the brain, lungs, liver, bladder, kidneys, paunch, reed, cæcum, and other natural divisions of the intestinal canal. The animal was not excessively fat, whilst the muscles were well developed and of a deep carmineous lustre."

This, I look upon as a complete triumph; and, in order that you may not suppose that it is a result which I had not solid philosophical grounds to anticipate, I will ask your permission to read part of a letter

that I published last winter, in criticism of Dr. Cobbold's paper, read to the Association of Medical Officers of Health.

"That the ova of parasites are to be found in town-sewage, and must sometimes be carried by it over the fields to which it is applied, no one can deny; but it is a rash assumption to say that therefore parasitical diseases must be increased by that means. Before the ova can arrive on a field in this manner, they must go through a marvellous amount of friction, rolling, and jolting. What proof is there that, after descending through the pipes of houses, and passing through, in most cases, several miles of sewers, performing one complete revolution in say, every inch—that is, in every 100 diameters,—they would arrive on the land in a state of fertility? But, supposing this to be proved, how long would it be before they could be taken into the stomach of a cow? All Dr. Cobbold's arguments were based on the assumption that nothing but grass can be grown on a sewage-farm. Let us, therefore, take the case of grass. A crop is obtained in, say, four weeks. One dressing of sewage is given immediately after the previous crop, or at the beginning of the twenty-eight days, and three other irrigations would be given at intervals of about five days. This would bring us down to the fifteenth day, leaving thirteen days for the crop to mature, and the soil to dry, before mowing, carting, etc., after which, as a rule, another twelve to twenty-four hours would elapse before the grass would be actually eaten. Therefore we are safe in saying that more than ten days would always elapse between the last irrigation and the consumption of the produce. Then, assuming that the ova survived all the perils of their journey from town to country, and farther escaped all the various obstacles which might retard their progress through the irrigating channels—against which 'double event,' however, the odds would be considerable,—to what beneficial or inimical influences would they be subjected during those ten days? To alternations of sunshine, rain, cold wind, warm wind, and, above all, the consequent fluctuations in their condition of moisture.

"Now, Dr. Cobbold laid great stress on the rapidity with which the ova of some parasites develop into their larval condition under the influence of moisture, accompanied—I presume, although he did not say so—with a certain minimum temperature. But if the temperature is lowered and the moisture abstracted during the processes, what then?

"It will be observed that I have here taken only the most favourable case for Dr. Cobbold; for, if he could establish the soundness of his theory under the most favourable conditions, it would go far to condemn sewage irrigation. But it is only fair to ask how he proposes to preserve fertility in the ova which I spread over my Romford farm last January?

"Let us go still a little deeper. The sewage flows, or, perhaps I should say, oozes gently, over the edges of my carriers, and for a few, very few, minutes trickles through the roots and lowest quarter or half-inch of the stems of the ryegrass, and, driving out from the soil the air which bubbles up through it, sinks down to fill the pores from which the air has been displaced, and carries with it into the surface pores all minute particles in suspension. The upper stratum of soil is, therefore, the natural place to look for the ova, and *not the grass*. The scythe, moreover, as a rule, does not descend as low as the height to which the sewage rises on the stems. I except, of course, all improperly managed sewage farms, such as Croydon, because the best agricultural result can only be obtained in conjunction with the best sanitary result, or, in other words, with economy of sewage and cleanliness. And if by exception an ovum did come into contact with a stem of grass above the scythe-line, by what law in physics would it be held suspended on the side of the smooth polished stem? And when the latter was cut, why should the vibration not shake off the ovum? If the ovum which has gone through so many adventures scatheless is to be safely conveyed to the haven of the cow's stomach, it has still to hold on to the grass during the alarming processes of raking, pitchforking, carting, uncarting, and distributing. Poor ovum! Can any one calculate the chances against each individual ovum that leaves its bearer during the three hundred and sixty-five days in the year ever attaining, through the medium of grass, to the proud position of a cysticercus?

"Wherever the chances are, they must at once be multiplied by 8 or 10; for, as a sewage-farmer, I venture to say that, when sewage-farming is properly understood, not more than 10 or 12 per cent. of the acreage of each sewage farm will be under grass. And no one will pretend that ova can climb up the stem of a cabbage or a lettuce; while as to other produce, potatoes they equally could not reach, and to carrots, turnips, or mangold wurzel, they would not have access for some weeks before harvesting—and they would be more obstinate than I take them to be if they resist 'pulling,' scraping, washing, 'pulping,' etc."

You will see that in this letter, and before I had any actual proof of the truth of my views, I nevertheless guarded myself from taking under

my protection *all* sewage-farms; and the truth is that, fortunately and curiously, but still in accordance with all that we know of the working of the laws of Nature, the same conditions of sewage-farming that are safe from any danger of spreading entozoic disease, are, as I hope I shall presently satisfy you, safe from other dangers; and, conversely, the same conditions which are dangerous for the one are also dangerous for the other.

I have heard my friend Dr. Letheby say with great unction, and with that peculiar air of conviction which makes whatever he says impressive, that all sewage-farms are "*pestilential swamps*"; and I believe that this is a very accurate description of many, and I even fear of most, sewage-farms. Sewage-farms are laid out, as a rule, by civil engineers, who have never condescended to study agriculture, and who, like many persons in every occupation of life, lose sight of the end in the means. The engineering works for the conveyance of sewage from a town into the country are only the *means*; the agricultural utilisation of the sewage is the *end*; and the means must be subordinated to the end. To take only a few of their mistakes: the equal and uniform distribution of water over the surface of the land by irrigation during the night is a problem of such extreme practical difficulty, that it is not too much to say that it is a thing which cannot be done; yet, as a rule, no provision is made for storing sewage at night. Again, no farmer thinks of applying over a term of years more manure to his crops than he thinks they can consume; and, if he be in any doubt, he endeavours, directly or indirectly, to get a chemist to advise him how much to put on. Yet, because one hundred is an easy number to remember, it is the fashion among engineers to lay out only one acre to receive the sewage of every hundred persons, and to decree that the plants upon that acre shall consume all this tremendous quantity of nitrogen. I have proved that Italian ryegrass (*Lolium Italicum*) can only make a certain number of efforts towards reproduction, or, in other words, yield a certain number of crops in its lifetime; and also that the most vigorous of these, to the number of nine or even ten, may, by proper management, be crowded into one season. Yet it is the fashion among engineers to lay down an entire sewage-farm with nothing but Italian ryegrass, ignoring the practical necessity for rotation. All botanists and all farmers know that the most valuable of cultivated plants will not flourish—in some cases will not even grow—in waterlogged land, but must have a good porous well aerated soil; yet engineers in large practice will argue at length against draining land which is to be irrigated with sewage.

But, if sewage be run on in a dark night in quantities in excess of the requirements of the plants, on soil that is waterlogged, covered, or rather partially covered, by plants that are exhausted, the necessary result is a "*swamp*"; and, if it be not "*pestilential*", it ought to be. Dr. Letheby should not, however say that, because the sewage-farms which he has visited were all, as a matter of fact, "*swamps*," and also, in his judgment, "*pestilential swamps*," therefore *all* sewage-farms must be the same. This is a complete *non sequitur*. He should point out the effect produced in the particular instances, and call for a remedy. Let us on the present occasion endeavour to do this.

Sir William Thomson told us the other day at Edinburgh that the most brilliant achievements of science have, after all, been but the sober rewards of careful measurements and long continued labour. Let us, then, proceed on the only true scientific method, and measure everything with which we propose to deal—land, water, manure, and crops. The moment we do this, the unscientific ignorance which applies the sewage of 100 or 150 persons to every acre of a farm, over an indefinite term of years, stands out in its native monstrosity.

You are all familiar with the determinations and estimations of the ammonia voided in every twenty-four hours by mixed populations, made by Lawes and Gilbert, Hoffman and Witt, Thudichum, Way, and many others. The average of these calculations works out at over 12 lbs. per head annually; but, if we make the allowance for waste made by Lawes and Gilbert—which, however, I do not believe to be necessary—we still have the large quantity of 10 lbs. a head, or 1,000 lbs. for 100 persons, to be applied to one acre of land year after year. To get an easy comparison, let us take the nitrogen-equivalent of this quantity of sewage estimated in guano. The best Peruvian guano only contains 16 per cent. of ammonia; therefore the sewage of 100 persons is equal in ammonia to 6,250 lbs., or 2 tons 15 cwt. 90 lbs., of guano. It is quite true that guano is much richer in phosphoric acid than sewage; but still the ammonia is the standard by which it is sold; and, when I say that 2 to 3 cwt. per acre is an ordinary dressing of guano, and 4 to 5 a large one, you will see how monstrous are the doses administered by some engineers.

It must be borne in mind, however, that from the fact of the ammonia being supplied by the sewage in a state of solution—ready cooked, as it were—very much larger crops can be grown, and there-

fore larger quantities of manure consumed, than by ordinary cultivation. Still it appears exceedingly doubtful whether—having regard also to the commercial side of the question—it will ever be practicable to utilise the sewage of more than twenty to thirty persons per acre over a term of years.

It is evident that the reduction from 100 or 150 to 20 or 30 persons per acre, by increasing the total area to which the sewage is applied, would at once relieve Dr. Letheby's "pestilential swamp" of much of its bad character; and if the land, when so relieved, be treated according to the teachings of science, and also, I may add, of practical agriculture, I confidently maintain that the swampy and objectionable character vanishes at once.

Again, nothing could be more completely unscientific than what is known as the "catchwater" system of irrigation. Not to weary you with engineering details, I may briefly describe it as a system which necessitates a saturated condition of both soil and subsoil to admit of the sewage being passed over the surface of successive areas of land, overflowing at the lower edge of each into a "catchwater" ditch which conveys it to the next area, the effluent water eventually overflowing, in its turn, the edge of the last area, and running off the surface into the ditch which conveys it to the river, the first area receiving too much sewage, and the last too little. On this system there is simply no guarantee at all that the effluent water has been exposed to any purifying process. It is generally clarified and sometimes purified, but the whole thing is a happy-go-lucky affair from first to last. Accordingly we have found, in the case of four distinct farms laid out on this principle, that what had been predicted on theoretical grounds, was actually taking place in practice, and that something like a third of the organic matter in solution was escaping in an unoxidised form; and, what was even more satisfactory to me, we found barely a trace of organic matter in an oxidised form.

This danger, however, at once disappears on a farm laid out as is my Romford farm, where the sewage cannot escape without passing through five or six feet of constantly re-aerated soil, in its intermittent passage through which the organic matter is minutely, almost infinitely, subdivided by the grains of earth, and washed in the air contained in the interstices, which it displaces and forces to bubble up to the surface. Moreover, when a farm is properly laid out and properly managed, instead of the sewage being allowed to flow for many hours consecutively over the same individual square yards of land, in quantities far in excess of the wants of the plants, a few square yards only are treated at one time; and when these are moistened the sewage is passed on to a fresh area. Thus the sewage is economised, and the land begins to be re-aerated as soon as the sewage begins to move downwards to the under drains.

Frankland's "intermittent downward filtration" is, therefore, the same as scientific irrigation, *minus* the assistance of vegetation.

Two dangers will, however, occur to the medical mind as attendant on all sewage irrigation, namely, malaria and well-pollution. Malaria is supposed indeed to be an almost necessary attendant upon all irrigation, and so I believe it is in most cases, simply because irrigation coupled with artificial drainage has been hitherto unknown. Low lands have generally been chosen for irrigation from motives of economy; they are not drained; in most cases their subsoils are naturally saturated, and vast quantities of water are superadded. The soil is generally rich and built up of the decomposing vegetation of centuries, while the grass growing on it (not to take the case of rice-fields, which are artificial swamps) is rank. The long roots of this rank herbage push down into the unoxidised organic matter, and make little capillary tubes in the soil through which a saturated solution of organic matter is evaporated into the atmosphere. But this dangerous condition of things at once ceases, the moment under-drainage of the subsoil is made to supplement irrigation of the surface, whether the liquid employed be plain water or sewage. The danger of well-pollution also disappears when under-drainage is introduced coupled with intermittent irrigation, aeration, and moderate doses.

The sewage question is therefore solved, and the dangers arising from sewage removed by its direct application to land.

But the benefit derived from this system is not merely negative—it is also positive. Sewage-irrigation enormously increases the productive power of the land—provides, in fact, a new source of food for the people, and by making bread, meat, vegetables, milk, butter, and cheese probably cheaper, but at all events more plentiful, will feed the masses better, and enable them better to resist disease. The sewage of the urban population of Great Britain alone, expressed in wheat, represents a minimum of 675 millions of quarter loaves of bread, but it is specially adapted for the production of milk. Now it is notorious that the milk-supply of our large towns, even when "stretched" to the utmost by the aid of the water-companies, is ludicrously small, and I believe that the

stunted and weak frames of our town populations are due to the absence of milk from their diet as children, even more than to bad air. Milk is the great source of soluble phosphate, out of which children manufacture the bones of strong men. To tell the children of England to make these bones without milk, is like the order given to the children of Israel to make bricks without straw. Let medical men insist on sewage being applied to land, and they will remove one principal source of disease, while by the same stroke strengthening their patients to resist diseases arising from other sources. They will, in short, substitute Food for Fever.

## THE ANATOMICAL RELATIONS OF HYPERTROPHY OF THE CERVIX UTERI.\*

By ROBERT BARNES, M.D.,

Obstetric Physician to St. Thomas's Hospital; Examiner in Midwifery to the University of London and the Royal College of Surgeons.

A RARE opportunity presented by the care of Mr. Stewart, Curator of St. Thomas's Museum, enables me to offer an accurate description of the anatomical conditions connected with hypertrophic elongation of the cervix uteri. Nothing is known of the history of the woman who furnished the specimen, except that she was advanced in years. The whole pelvis and its contents were removed without disturbing their relations. A careful vertical section was made in the median line, thus giving two preparations, and exhibiting a typical illustration of this affection, the accuracy of which cannot be impeached. The specimens are so bulky that they could not travel without risk. I have, however, got our Librarian, Mr. Denison, to make an enlarged drawing of the one which shows the parts best. The drawing is very exact. [It was exhibited.]

The entire length of the uterus is about seven inches. The fundus and body are somewhat lower in the pelvis than natural; the body has undergone apparently very little elongation, the chief excess of longitudinal growth being spent upon the cervix. The two lips of the os uteri are much hypertrophied and somewhat everted. They form a mass covered by the everted vagina outside the vulva. That this is the result of downward growth, not of simple prolapsus or stretching, is seen in the condition of the bladder and of the ante-uterine and retro-uterine peritoneal pouches. The base of the bladder is carried down along with the down-growing interior wall of the cervix uteri, forming a sacculated pouch below the level of the urethra, and therefore below the symphysis pubis. The urethra is also distorted into a curve, of which the convexity looks upwards, the bladder-end of it being carried downwards along with the base, so that a catheter to pass would have to be directed first, a little upwards, then backwards and downwards. The body of the bladder is enormously enlarged; that is, its capacity is greatly increased, but its walls are not materially thickened. The change seems to be simply distension, probably the consequence, not of actual obstruction to the passage of urine, but to a habit of long voluntary retention acquired through the desire to avoid the irritation caused by the dribbling of urine over the protruded mucous membrane of the everted vagina. The fundus rose as high as the umbilicus, and considerably higher than the fundus of the uterus. The peritoneum, descending behind the abdominal wall, is reflected upwards over the bladder at a point about two inches above the symphysis pubis. It descends behind the bladder quite down to a point on a level with the sacculated pouch of the bladder; that is, below the level of the lower margin of the symphysis pubis. Rising over the fundus uteri, the membrane descends behind, forming a Douglas's pouch quite below the vulva. The only part not much disturbed is the rectum. Of course there is no apparent vagina, since the down-growing os and cervix uteri have carried the vagina before them, completely everting it and turning it into an investment of the protruded parts.

The specimens and the drawing exhibit very clearly the danger of amputating the hypertrophied cervix. It would not be possible to remove more than a portion of the os without opening the retro-uterine peritoneal pouch. It also explains the difficulty commonly encountered in keeping the protruded parts inside the pelvis by pessaries. The drawing exhibits the relations of the bladder, uterus, and rectum, exactly as they were found; that is, in apposition with each other. There were no folds of intestine descending between them in the anterior or posterior peritoneal pouches.

## ON THE UNITY OF THE SYPHILITIC POISON.\*

By S. MESSENGER BRADLEY, F.R.C.S.,

Lecturer on Comparative Anatomy, etc., in the Royal School of Medicine  
Manchester.

No fact in surgery is better established than the auto-inoculability of soft chancre. Experiments have also long since proved that the soft sore may be conveyed by means of inoculation from one individual to another. For a time, the inoculability of the hard sore was denied; but, more recently, experiments have demonstrated the fact that the hard or infecting chancre is in like manner capable of inoculation upon a virgin subject, there giving rise to a sore similar in nature to the original lesion, and in course of time, like it, followed by a train of constitutional symptoms. Furthermore, it is admitted by the so-called dualists, that a sore is occasionally grafted upon a subject already syphilised by matter taken from a true infecting chancre. In this case, they affirm that the sore so produced is invariably soft. This circumstance has not led them to infer the common origin of the two lesions, but that the soil (*i.e.*, the system of the syphilised subject) is so changed as altogether to modify the character of the inoculated virus without converting it into the "materies" of true soft chancres. It is manifest that, in order to prove the common origin of the syphilitic poison—in other words, to prove the unity of syphilis—it is necessary to produce a soft sore upon a virgin subject by direct inoculation from a hard sore, *i.e.*, to produce a sore indefinitely, capable of auto-inoculation and never followed by constitutional symptoms. I have made numerous experiments to ascertain whether this was or was not possible, and here give the results of these experiments.

My subjects were monkeys, kittens, and guinea-pigs; the virus which I employed was obtained from cases of syphilis met with in private practice, in the Lock Hospital, and in the venereal wards of the Manchester and Chorlton Workhouses. I obtained the matter for inoculation by scraping the surface of the sore, prior to cicatrization, with either a piece of glass or an ivory vaccination-point.

The great majority of my experiments gave negative results; these I do not record, as they prove nothing. In two instances (one in a guinea-pig, and one in a kitten), the inoculation was followed, after the interval of two or three weeks, by local thickening at the site of puncture, and, later, by the outbreak of constitutional symptoms. The guinea-pig died within a month from the commencement of the basal thickening of the chancre, with disorganisation of one eye and extensive ulceration about the mouth and soft palate; the kitten I killed at the end of the eighth week, and found syphilitic gummata in the kidneys and liver.

Omitting failures and the two cases of syphilis mentioned above, I obtained the three following successful results.

**EXPERIMENT I.**—On March 28th, 1871, I took some virus from a syphilitic sore upon a female, aged 19. The sore, which was situated upon the left labium, was first noticed three weeks before. It presented a well-defined base, and very scanty secretion. There were mucous patches about the anus, and a papular syphilitic eruption upon the arms and legs. A kitten was inoculated with this matter the same day, upon the inner side of the shaved haunch. On the second day, there was evident irritation at the site of inoculation, which, on the sixth, had developed into a typical soft chancre. Matter taken from this sore was inoculated upon the opposite thigh, where it produced a precisely similar result. On July 27th, the chancres were both healed; there was no adenopathy, nor constitutional symptoms.

**EXPERIMENT II.**—On April 3rd, I took virus from a syphilitic female, aged 22. The sore, situated upon the labium, had a hard base. There were multiple inguinal adenopathy, and syphilitic sore-throat. I inoculated a guinea-pig with this virus the same day, upon the ear and haunch. The ear gave a negative result. On the eighth day, the haunch presented a characteristic soft sore, which freely suppurated. I successfully inoculated the same guinea-pig in two places, with matter taken from this sore.

July 27th.—The chancres were all healed. There was no hardness at the base of cicatrices, and no constitutional symptoms.

**EXPERIMENT III.**—Virus was taken from a male, aged 26, on May 17th, 1871. The chancre was situated behind the corona glands, and had a well-marked cartilaginous base. There was multiple inguinal adenopathy. The sore had appeared fifteen days before, and three weeks after an impure connection. At the present date (July 28th), the patient is covered with a papular syphilitic eruption. I inoculated a guinea-pig the same day with this virus in three places; only one puncture, however, was successful. The resulting chancre was not

mature until the fourteenth day, when it suppurated freely. With matter taken from this sore, I succeeded in inoculating this same guinea-pig and a companion rodent, which chancres in their turn gave rise to inoculable matter. On July 27th, the chancres had healed. There were no constitutional symptoms.

It is necessary for me to state that, in these experiments, the initial lesion was never irritated by any application; I merely used the secretion obtainable from the surface of the untreated sore. When the sore was irritated by savine, it was much easier to procure abundant, and, as a rule, readily inoculable pus.

I never succeeded in obtaining positive results with matter taken from a phagedænic sore, or by scraping the surface of one which was entirely void of all secretion.

Such are the results which I have obtained; and, supposing my experiments to be verified by future observers, I do not see how we can refuse to admit the correlation, the common origin, and the convertibility of the two sores. Undoubtedly this convertibility is very seldom witnessed, the tendency being, here as elsewhere, to "breed true." Noting the fact that grave constitutional symptoms were nearly always preceded by a serious and obstinate character of initial lesion, and that a mild and benignant attack of secondaries was nearly always preceded by a slight and readily healed sore, Carmichael, Bassereau, and others, described no less than four perfectly well-defined classes of syphilitic sore, each followed by its own peculiar train of constitutional symptoms. The rarity with which the convertibility of which I speak is witnessed, need not surprise us. It is, indeed, not without its parallel in medical literature; for we meet with a strictly analogous phenomenon in the clinical history of the vegetable parasites. It may, indeed, be held as settled, that the fungi infesting the human body are all interchangeable; thus it has been proved that the mycelium of aspergillus is produced by the germination of the achorion; that favus is caused by the implantation of the torula; that favus may assume the form of tineæ tonsurans; that tineæ tonsurans is produced from tineæ circinata, and, *vice versa*, that tineæ versicolor is produced by the implantation of the fungus of tineæ tonsurans, or from the oidium; that the aerial spores of penicillium develop into torula; that sarcina may develop from the spores of penicillium; that sarcina, aspergillus, and penicillium are derivable from the same source; that torula may assume the form of mucor; and many more facts of the same kind, all tending to complete the chain which connects in one family group the highest with the lowest fungus. Yet it must not be supposed that because this power of convertibility exists, it often takes place in the human subject; on the contrary, it very rarely takes place; for, says Dr. Tilbury Fox, "the upshot of the matter is this: that the achorion, even if identical in nature with other epiphytes, cannot be expected to produce upon the human surface any variety of tineæ other than favus, except as the rarest phenomenon; and inasmuch as it is the most developed condition of favus in which the spores become nucleated, budding is apparent and fructification attempted; the soil which suffices for other phases will not conduce to the retrograde growth of achorion, which has the tendency (alike common to fungi) to reproduce itself"; and, further, after demonstrating the common origin of sycosis, tineæ tonsurans, and favus, he adds: "there is no ground for rejecting the identity of tineæ favosa and tineæ tonsurans in our inability to produce artificially the one from the other, except but very rarely." It seems probable that the same causes which thus operate in this low region of the vegetable kingdom (these causes being differences in the soil and in the age, etc., of the seed) are the active agents in determining the character of the syphilitic sore.

The precise force which each of these causes exercises, we are not yet in a position to decide. There is some reason for believing that the interchange of character between the two sores is more frequently witnessed than is commonly believed. I may quote in support of this statement, the impartial evidence given by "the Committee appointed by the Secretary of State for War and Board of Admiralty to Inquire into the Pathology and Treatment of the Venereal Diseases." At page 9 of their report, it is stated that "hard sores do not necessarily contaminate the constitution, while, on the other hand, constitutional symptoms occasionally follow the presence of a sore which might have been regarded as a simple local sore by a practised observer."

After all, I do not consider this question of unity or duality to be one of much practical value. Granted that these experiments, when verified by the experience of others, demonstrate the unity of the poison, none the less will it be true that the original virus has given rise to two diseases, which are for all practical purposes entirely dissimilar, differing in symptoms, in prognosis, and in treatment. At the same time, I cannot admit that this fact of unity is *entirely* a sterile and useless fact, for two reasons; in the first place, the essential oneness of the syphilitic poison being proved, it clearly follows that we should in all cases await the appearance of constitutional symptoms (the first of which may pro-

\* Read before the Surgical Section at the Annual Meeting of the British Medical Association at Plymouth, August 1871.

bably be regarded as the multiple inguinal adenopathy, always present when infection of the system is about to take place) before commencing a course of mercurial treatment; and, in the second place, it should make us more guarded in prognosticating constitutional infection in cases of hard chancre, and certain immunity from all secondary symptoms in undoubted cases of soft sore.

## THE TRIALS AND DIFFICULTIES OF A HEALTH-OFFICER.\*

By DAVID DAVIES, M.R.C.S.

Inspector of Health for Bristol.

THE appointment of health-officers being of recent date, and not yet of universal adoption by the great centres of population, a few words on the difficulties and trials peculiar to such officers seem to be desirable, especially at the present time, when we are promised better legislation on the subject, which, however, from session to session is deferred—our legislators having hitherto found other matters to be of more importance than the health of the people. Without further preamble, I will enumerate those difficulties as they have cropped up in my own experience.

1. *The want of Early Information of the Occurrence of Infectious Disease in a Family or Neighbourhood.*—At present this information is only at the command of a health-officer through the unpaid courtesy of his professional friends, or by keeping up a continual system of espionage over other people—a system which is never pleasant, and one that often proves unsuccessful until much mischief has been done by the spread of disease.

2. *The Confused State of our Sanitary Laws, many valuable Enactments being Permissive and not Compulsory.*—As an instance of the complete manner in which our laws have failed to point out the different authorities for doing certain imperative sanitary work, take the building of hospitals for the isolation of persons suffering from infectious diseases. Under the Sanitary Act of 1866, boards of health may build such hospitals. Are these for the admission of paupers or not? or must paupers be provided for by the respective unions? Hence arise letter-writing and disputes between nuisance-authorities and boards of guardians, whilst small-pox or other fatal diseases may be spreading far and wide; each party considering its chief duty to be that of keeping down the rates. These permissive clauses have produced such bad results that I know at the present time a large union containing a very large workhouse without a single ward for the isolation of a case of infectious disease either in the workhouse or out of it; and I knew until very lately a large and important city without any such ward.

3. *The Separation between the Registration of Deaths and the Sanitary Authorities.*—The latter cannot get early intimation of death from the local registrars without paying such sums as the latter may please to charge for the information. I find no fault with the registrars, as with them it is a mere matter of business; but it is evident that the system is wrong, and that the deaths registered should as soon as possible be submitted to the scrutiny of the health-officer.

4. *The Division of Nuisance-Authorities, and the want of a Central Power to make them act in unison.*—I will here narrate a remarkable instance of this. From the county of Somerset a brook, which was within the memory of man a clear trout-stream, runs through a part of Bristol. A nuisance has been created by a glue-factory in the county, so as to render this brook a veritable Styx. It contained black mud saturated with animal matter, which in many places was a yard deep, and which, seething under the summer sun, gave out thousands of cubic feet of poisonous gases. The nuisance was made by A in the county. It then ran into the brook which formed the boundary between the lands of B and C, who had no hand in creating the nuisance. It then ran through a populous district under the jurisdiction of the Bristol Board of Health. The Board of Health called upon the guardians of the poor for that part of the county to abate the nuisance. In compliance with this the guardians, after taking the best legal advice, required B and C to cleanse the brook in the county and remove the nuisance. B and C, who were certainly innocent parties, pleaded non-liability. The county magistrates, after hearing the case argued by eminent counsel for some hours, made an order on B and C, because the nuisance was found on their land. B and C complied. Within the district of the Board of Health, D was in the same position as B and C in the county. The Board of Health summoned D before the Bristol magistrates, who dismissed the case, stating that D, being an

innocent party, was not liable, but that the Board of Health must find out the originator of the nuisance, who lived out of the jurisdiction of the Bristol magistrates, and had certainly no right to enter the land of D to remove the nuisance. Thus we have one law in the county of Somerset and another in Bristol; and the brook is now becoming as great a nuisance as ever. Which legal authority is right, is not for me to determine: either side is made to appear plausible in the hands of counsel. I could adduce other instances of want of unison from divided authority and the consequent failure of health-authorities.

5. *The Non-Adoption by our Profession of an Uniform Nosology.*—Hence the returns of deaths (occasionally even when made by able men) would puzzle wiser heads than mine. Some of our *confères* will insist on calling a bad case of enteric fever "typhus", and a mild case of typhus goes by the name of "typhoid", or either may be disguised under the milder name of "gastric fever". Others enter as fever on the death-returns every case which has terminated with febrile symptoms and coma, although the cause of all the symptoms may have been disease of the kidney or some other important organ. Others of our body have peculiar views of the identity of common sore-throat, scarlet fever, and diphtheria. During the year, a health-officer, if he adopt a modern and specific nosology, must be often hurt by the returns of the Registrar-General, by which he will be informed that typhus, or perhaps cholera, has visited his district, although he is morally certain that neither has done so. But enough of this; let us hope that when we have one portal for our profession these differences will disappear.

6. *The importance attributed by the Public to the mere Figures of the Registrar-General, without regard to Locality, Causes of Death, or the Ages of the Dead.*—One district may be celebrated as a residence for invalids on account of its bracing air. Lethal atmospheric influences, such as prevailed in the spring of 1870, may sweep over this locality, and, by capillary bronchitis, destroy the old and the feeble in large numbers. During the same year that pest of our race, which heeds no sanitary conditions at our command—scarlet fever—may, like a destroying angel, gather the finest of our blossoms. Or a locality may be so celebrated for its hospitals and the medical and surgical attendance procured there, as to attract to it such a large number of persons suffering from fatal diseases and injuries, as, in conjunction with the workhouses, to raise the deaths in public institutions to 14 or 15 per cent. of the total. The public look only at the totals of the Registrar-General, and shake them in one's face, like Shylock his bond. When an adverse combination, due only to atmospheric influences, or an uncontrollable epidemic happens, the public will have their say about it. Newspaper editors write learned articles on the subject, which, as a rule, are very wide of the mark. Every one that can wield a pen writes to the local papers pointing out the cause of it all. Even sometimes an old-fashioned member of the medical profession will join the hue and cry, and for ever condemn all that is local. The health-officer is everywhere greeted with anxious and dubious inquiries. The public evidently think somebody ought to be hanged; and he is the most likely victim. He walks about like a "thing of shame", supported only by his *mens conscia recti*. He knows the lives he has saved; the public know how many they have lost. No one appreciates more highly the intellect brought to bear by the Registrar-General on the figures in his possession than myself. Had that high authority been furnished with further information regarding distant localities, and if he could by any process of elimination distinguish the deaths which are truly local, I respectfully conclude that many of his valuable quarterly reports would differ widely from the past—that some localities reputed healthy would sink to the bottom of the list, and others now reputed as unhealthy would correspondingly rise; that many of our country districts which send their sick to die in the large towns would change places with the latter. But the management of figures where there are so many modifying factors is a herculean task.

7. *The Death of many Infants under One Year Old is one of the greatest troubles of a Health-Officer in Large Towns.*—The majority of these deaths arise from causes over which a health-officer has no control, which are moral rather than physical in their origin. In all large towns there is the production of offspring by individuals who have no moral right to the privilege. They have not the physical means to support them, nor have they the desire to perform the duties of parents to them after they are born. They are viewed by many as unwelcome interlopers on their sensual enjoyments; and, I am afraid, that occasionally grim and undeserved poverty destroys the paternal and maternal instinct. Many die from sheer neglect and want of breast-milk or other appropriate food; others die from exposure, without proper clothing, to our variable climate; but a vast number die from want of medical advice and good nursing when suffering from diseases incidental to childhood, such as measles and whooping-cough. When either of these diseases sweeps over a poor locality in the cold spring

\* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

months the number of these little victims is appalling. No means at the command of a health-authority can alter these figures. "More want they the divine than the physician." A more extensive acquaintance with the facts of political economy, a more acute appreciation of moral responsibilities, and a greater power of self-restraint, among the lower stratum of our population, can alone remove this opprobrium of our large towns. The figures tell against the locality in which the deaths occur, but they are no index of the general sanitary condition of the place.

Many other points I could mention which occasion grief and pain to health-officers, but over which they have not the slightest control, and for which they are not in the least degree responsible.

I hope these few remarks will induce others of greater experience than myself to describe their own difficulties, so that we may learn something from one another's trials, and possibly point out to the legislature how it may best help us.

### SUGGESTIONS FOR THE EMPLOYMENT OF NITRITE OF AMYL IN THE COLLAPSE AND CRAMPS OF CHOLERA.

By TALFOURD JONES, M.B.Lond, University Medical Scholar,  
Physician to the Brecknock County and Borough General Infirmary.

THE existence of cholera on the Continent, and the presence of sporadic cases in this country, induce me to offer some suggestions respecting the employment of a new remedy in this terrible disease. This new remedy is the nitrite of amyl; and my reasons for advocating its use in the collapse and cramps of cholera will perhaps best be set forth by the enunciation of the following propositions.

1. That the collapse of cholera is the result of an impediment to the circulation of blood through the lungs, and that this impediment is due to the contraction of the muscular fibres of the minute pulmonary arteries.
2. That the cramps of cholera are due to a like spasm or contraction of voluntary and involuntary muscular fibre in other parts of the body.
3. That nitrate of amyl possesses the property, when taken into the system, of causing relaxation of muscular spasm and arterial dilatation.
4. That in many features there is a considerable resemblance between cholera collapse and asthmatic collapse.
5. That nitrite of amyl is a remedy capable of giving instant relief in asthmatic collapse.

I will begin by offering some remarks as to the soundness of the first two propositions.

The exceedingly careful *post mortem* examinations of Dr. Parkes\* show that in cholera collapse the lungs are found shrunken, light, dry, and pale; the left ventricle of the heart is contracted and nearly empty; its right cavities, the trunk of the pulmonary artery, and the systemic veins, are distended with blood, and the mucous membrane of the intestine pale. "That there is," he observes, "some impediment or arrest of the circulation in the capillary system generally, and in the pulmonary capillaries in particular, appears almost certain."

This impeded pulmonary circulation is indicated, during life, by the comparative emptiness of the systemic arteries—the pulse being small and feeble, or even entirely absent, at the wrist—and by the fulness of the systemic veins and the lividity of the surface.

What is the cause of this impediment to the pulmonary circulation? Dr. George Johnson, in his recent paper read before the British Medical Association in Plymouth, says it is due to contraction of the minute pulmonary arteries; that a similar arrest of the circulation occurs as a result of acute apnoea; and that embolism of the pulmonary artery has in several recorded instances given rise to the most characteristic symptoms of cholera collapse—such as blueness of the surface, shrinking of the features, paleness, coldness of the tongue and breath, urgent dyspnoea, with loud peculiar respiration over the lungs, and a feeble whispering voice. The recently published lecture of Sir Thos. Watson will go far to strengthen Dr. Johnson's theory, which, he says, is founded on a true analogy, and is consistent with the symptoms noticed during life and with the conditions discovered after death. We may, therefore, legitimately regard it, until fairly refuted, as a sound as well as a most ingenious and important theory. In truth, it derives strong confirmation from the fact that it unlocks, like a right key, the whole of the pathological intricacies of the disease.

The very painful muscular cramps in cholera are ascribed by Dr. Johnson to the action of the choleraic poison on the muscles; and he supposes that the contraction of the minute pulmonary arteries is due to a like cramped state of the muscular fibres of these vessels, which also he refers to the specific poison of cholera.

The injection of hot fluids into the veins of patients in a state of collapse has been often followed by good effects. Dr. Johnson holds that they act chiefly by relaxing through their warmth the spasm of the smaller arteries. The blood then flows on again, and the symptoms of collapse are for a time removed. There are many other facts that might be advanced in support of this theory; but it is sufficient for my present purpose to point out, as I have in the preceding recapitulation, the more important ones bearing on the pathology of the collapse.

Assuming, now, that the pathological causes of collapse and cramps are such as I have enunciated (and I firmly believe them to be right), what, then, is the physiological antidote to the poison which gives rise to such muscular contractility?

In my third proposition I say that nitrite of amyl, when taken into the system, causes relaxation of muscular fibre, and induces dilatation of the smaller arteries. In support of this statement it will be necessary to say a few words about the action of this remedy; and this is all the more needed, since I find from inquiry that the nitrite of amyl is most inadequately known; that its employment in medicine has hitherto been most limited; and that very little has been written about its action in disease. As an instance of this it may be stated that, since the publication in the BRITISH MEDICAL JOURNAL of February 26th, 1870, of the two cases treated by amyl, and communicated to the Clinical Society on the 11th February, 1870, by Dr. Lauder Brunton and Dr. Anstie, nothing has appeared in the columns of the JOURNAL on the action of this remedy.

Nitrite of amyl,  $C^{10}H^{11}O, NO_3$ , is an amber-coloured fluid, smelling like the essence of ripe pears. The experiments of Dr. Richardson show that it causes paralysis of the chain of organic nerves which supplies the contractile power of the blood-vessels; and that, applied to the olfactory filaments by inhalation, the impression is conveyed along the ganglionic nervous tract, and causes more or less paralysis of the vaso-motor nerves, and induces muscular and arterial relaxation.

Though it produces its characteristic effects directly upon the walls of small arteries, yet it is highly probable that it also acts upon most, if not upon all, unstriated muscular fibre.

I have now employed it in many cases of disease, and have likewise given it experimentally to some fifty friends, and have found that its administration invariably causes increased frequency of cardiac pulsation, dilatation of the arterioles, flushing of the face, warmth of body, and perspiration. It may be administered by inhalation, by the mouth, or by subcutaneous injection. It is beyond the scope of this paper to dwell further on this interesting remedy, or give details about its varied uses, mode of administration, etc. Those of my readers who may wish to learn something more about it will find in the next number (the October number) of the *Practitioner* a paper by me on the subject.

I have stated that in many features there is a considerable resemblance between the collapse of cholera and that of asthma. Thus the dusky or leaden hue of the surface, the coldness, the clammy perspiration, the feeble pulse, and the general signs of an impeded pulmonary circulation, are in both much alike. Dr. Johnson has noted this similarity, and says that the main difference between choleraic and asthmatic collapse consists in this—that in asthma there are a primary apnoea the result of bronchial spasm, and a secondary asphyxia or pulselessness consequent on contraction of the minute pulmonary arteries. On the other hand, in cholera there are a primary asphyxia, and a secondary apnoea consequent on the arrest of circulation.

That nitrite of amyl is a remedy capable, as I have stated in my fifth and last proposition, of giving instant relief in asthmatic collapse, will be seen from the following case, in which its employment was followed by the most striking results.

At twelve o'clock on the night of October 23rd, 1870, a woman begged I would instantly go and see her daughter, who, she said, was in a dying state. On entering her bed-room, I saw the patient, a young married woman, half undressed, sitting on the corner of the bed, and holding on to the bed-post. There was a dusky, leaden hue about her face, neck, chest, and hands, and a cold, damp sweat clung to her. Her body generally was cold, but her feet and legs were of an icy coldness. Her pulse could scarcely be felt. She was making violent efforts to breathe, and each inspiration was accompanied with marked recession of the supraclavicular and the intercostal spaces. Loud sibilant *râles*, with sonorous rhonchus, could be heard over the greater part of the chest. She tried to speak, but could only make faint gasps. The thought instantly occurred to me, that the nitrite of amyl, which, it should be mentioned, I had procured only a short while before, might be of use. I

\* *Researches into the Pathology and Treatment of Asiatic Cholera.* By F. A. Parkes, M.D. Lond. 1869.

† *Lecture on the Diffusion, Pathology, and Treatment of Asiatic Cholera.* By Sir Thomas Watson, Bart., M.D. (BRITISH MEDICAL JOURNAL, Aug. 5th, 1871.)

ran back to my house—close by—and returned with the bottle. Five drops of the nitrite were applied, on a piece of lint, to her nostrils. In half a minute her face began to redden, and in about a minute it was deeply flushed; her heart palpitated; her carotids throbbed; warmth of body quickly returned; and her breathing became easy. The effect was marvellous, and I felt nearly as much astonished as the patient and her mother. She now became able to converse, and told me that she had been subject to asthma for many years, that her father was asthmatic, and that she had never before had such a severe attack as this. She accounted for it thus. In the early part of the day she was as well as usual; but that evening she remained out for some time, and returned home feeling damp, cold, and chilly.

In about ten minutes after the inhalation, the breathing became a little asthmatical; so we reapplied the amyl, and again she became perfectly easy, and then went to bed. Next morning, she told me that she had had a most comfortable night; the asthma was quite gone; and she was able to attend to her household duties.

In this case, the nitrite of amyl undoubtedly caused relaxation of the muscular fibres of the bronchial tubes. By the expansion of these tubes, the impediment to the entrance of air was removed, and it consequently had free access to the lungs. In addition, however, to this, there was also an impediment to the passage of blood through the lungs—due, probably, to a similar spasm or contraction of the muscular coats of the pulmonary arterioles. This is, I think, shown, not only by the condition in which the woman was, but also by the rapidity with which signs of a free arterial circulation followed the use of the amyl—rapidity, indeed, preceding even that of the complete relaxation of the bronchial spasm.

The question now comes, Will this remedy prove equally useful in the collapse of cholera? Will it relieve the frightful cramps? Will it, in fact, prove the physiological antidote to that poison which, when present in sufficient quantity in cholera patients, seems always to induce spasm of muscular fibre?

When reading, last month, Sir Thomas Watson's interesting lecture on Cholera, all at once the thought flashed through me, "Why, nitrite of amyl is the very remedy!" My mind reverted to my case of asthmatic collapse; and I pictured to myself cases of cholera collapse that had come under my observation. The resemblance of some of these to my case of asthma was most striking, and I came to the instant conclusion that the remedy that acted so magically in the one might be expected to act with similar certainty in the other. The remedy needs but a single trial in a genuine case of cholera collapse to enable us to judge of its medicinal value. I am perhaps over-sanguine, and am perhaps at fault in my pathological and physiological reasoning; but I confess I do, from my knowledge of the extreme therapeutical value of this insufficiently known medicine, anticipate important results from its employment in cholera.

In concluding, I will quote the last paragraph from Dr. Parkes's treatise on Cholera.

"Although the treatment of the severest forms of cholera has not hitherto been successful, yet, considering the virulent nature of the active cause, I think there is reason for congratulation that the medical art can do so much. It can arrest the disease in its premonitory stage; it can with tolerable certainty carry the patient through the consecutive febrile affection. It can successfully treat the milder cases seen towards the end of an epidemic. If at present the deep algide stage is beyond its control, there is no reason to dread that such will be always the case. I firmly believe that some great discovery will speedily reward the efforts of the pathologist, and that a more certain knowledge of the morbid changes in the blood will indicate to us the antidote to this poison, at present so terrible and resistless."

The pathological discovery is, thanks to Dr. George Johnson, now patent to everybody; and I venture to suggest the hope that the physiological antidote will be found in nitrite of amyl.

## DYSTOCIA: SUCCESSFUL REMOVAL OF A FIBROID TUMOUR OBSTRUCTING LABOUR.\*

By J. WALLACE, M.D. Edin.,

Assistant-Physician Liverpool Lying-in Hospital and Ladies' Charity.

THE following case is the first of a series which I hope to be able to lay before the Society, from time to time, as illustrative of dystocia or difficult or obstructed labour. It comes under the class of obstacle at the neck of the uterus, and is, perhaps, the most difficult to deal with, so far as the accoucheur is concerned, while at the same time it is one of the most dangerous to both mother and child. In looking over the records

of obstetric literature, I know of no instance which did not cause great anxiety to the accoucheur and all concerned; the rarity of the lesion giving rise to lack of experience, and, consequently, to doubtful diagnosis and want of decision in treatment.

Fibrous tumours are frequently met with in the unimpregnated uterus, and are occasionally discovered on the surface of the puerperal uterus in the form of nodules or small irregular bodies; but these give rise to little or no difficulty compared with what is experienced when the growth has so largely developed itself, either in the anterior or posterior lip and in the lower segment of the uterus, as to fill up the pelvic cavity to such an extent as to necessitate its removal, the use of the forceps, turning, embryulcio, or even Caesarean section.

Mrs. H., aged 44, primipara, requested my attendance June 10th, 1870. She had had occasional uterine pains during the morning. On examination, first of the abdomen, the hand at once detected an abnormal contour; and, secondly, *per vaginam*, the finger impinged upon a hard round mass, very like the foetal head (and mistaken for it by one gentleman), occupying the centre and left of the pelvic brim and cavity; and it was only after very careful examination that I discovered the os uteri high in the brim, and pointing to the right ilium, and not at all dilated. I desired them to send for me when the pains became stronger and more regular. At 12 P.M., Dr. Johnstone, of Russell Street, kindly accompanied me to give chloroform should we deem it necessary. It was thought advisable to administer it, after which I made another examination, and found the os uteri as large as a florin, quite dilated, and the head in the first position of Naegele. The irregularity in the shape of the abdomen was caused by the high position of the child, and a rounded mass which gave obscure fluctuation, lying in front of, and to the right of, the uterus, and occupying part of the umbilical and right iliac regions. A catheter passed into the bladder, showed that that viscus was lying to the right of the mesial line, above the brim and below the superior tumour already alluded to. The catheter passed in front of the inferior tumour, occupying the upper pelvic outlet. Passing the finger *per rectum*, I found it to lie behind and to the right of the inferior tumour, pushed deeply into the furthest parts of the sacral curve. By grasping the tumour between the fingers of the left hand in the rectum, and the fingers of the right hand in the vagina, I found that it was slightly movable, but not sufficiently so to enable me to push it upwards above the brim, or to lead me to anticipate the possibility of being able to do so subsequently; neither fluctuation nor cartilaginous crepitation could be detected. Still pursuing my method of diagnosis, I next punctured the tumour with a trocar passed *per vaginam*, but no fluid whatever escaped. The child was living; the mother's pulse was normal, and she showed no signs of exhaustion or febrile excitement. Indeed, such could not well have set in, as pains only came every twenty minutes. We therefore determined to wait and see what effect the pressure of the foetal head would have upon the growth, which I now concluded was fibrous in its nature, and occupied the left lower segment and the cervix of the uterus, protruding downwards into the pelvic cavity, and so tilting the os uteri to the right.

On the following day, June 11th, the os was found expanded to the size of a crown piece, and dilatable. The diagnosis of the case having been concurred in by Drs. Johnstone and Davidson, the latter gentleman then administered chloroform, while I began to explore the nature of the abnormalities at the pelvic brim. Its shape was that of the segment of a circle, similar to a quarter moon, one horn pointing to the pubis, and the other to the right sacro-iliac synchondrosis, the transverse diameter being less than two inches, and that corresponding to the conjugate and right oblique about four inches. Having resolved to attempt delivery, as the patient was getting anxious and somewhat exhausted, I first applied the long forceps over the forehead and occiput of the foetus, with difficulty, but found it was impossible to move the head or the tumour. I therefore withdrew them; and, having passed a flexible bougie into the rectum, and a catheter into the bladder, I made an incision into the tumour from the vagina and below the cervix, and found that the tumour could be enucleated without much difficulty, as the attachments to its capsule at the lower part were so slender that the finger easily broke them down. Having passed the fingers well round it, I grasped it with polypus uterine forceps, and dragged it down; but, finding that the instrument was too slender, I fixed the crotchet into it, and by this means was able to bring it down nearly to the outlet of the vagina, applying all the time considerable extractive force. Finding at this stage of the operation that it was attached by what may be termed a so-called pedicle, of about the thickness of two fingers, to the uterus, I combined torsion with extraction, and in this manner soon brought the tumour away entirely. It was, as I had concluded, a fibroid of a dense, solid structure, presenting a glistening, shining appearance, almost like a serous membrane, with the exception of one extremity where it had been attached to the uterus. It weighed fourteen ounces,

\* Read before the Liverpool Medical Society.

and measured six inches in length, three inches in thickness, and four inches in width. I presented it to the Museum of the School of Medicine, where it now is.

Delivery was completed by the re-application of the long forceps, with the assistance of Drs. Johnstone and Davidson, but unfortunately the left parietal bone was so much indented by the forceps that the child was still-born. This may be accounted for by the narrowing of the pelvic brim, in consequence of the descent of the superior tumour, which I discovered to be also a fibroid. I examined it thoroughly by placing one hand *in utero*, and the other on the abdominal wall, and found that the internal uterine surface opposite the fibroid left *in situ* was hard and cartilaginous, and combined manipulation gave a very deceptive feeling of fluctuation. There would not have been any difficulty in enucleating it had circumstances demanded it; but the absence of *post partum* hæmorrhage, and the exhausted condition of the patient, did not warrant further interference. Had hæmorrhage threatened or declared itself, I was prepared to carry out enucleation.

I need not trouble you with the details of after-treatment, further than to tell you that the administration of opium in large doses formed a leading feature in it, with soothing and stimulating applications externally, and antiseptic vaginal injections. At the end of a week she was out of all danger, and made an excellent recovery. Two months afterwards I examined the condition of the uterus. There was no vaginal cicatrix; and the fibroid which was allowed to remain had become so absorbed that no trace of its presence could be discovered; and up to the present date (May 10th, 1871) she menstruates regularly and normally, and is otherwise in excellent health.

I shall not detain you further than to state that other obstetricians have met with similar cases. Burns in his work on *Midwifery* relates a similar one, where the choice lay between removal of the fibroid and Cæsareotomy. He removed it, and the woman made an excellent recovery. Cazeaux dilates at great length on a case which was seen by M. Dubois and others, as grave doubts were entertained whether the diagnosis was correct. He says: "After proving our incapacity of making an exact diagnosis of the nature of the tumour, it was divided into two, with the view of enabling them to extract the dead foetus. The patient was delivered, but died half-an-hour afterwards." M. Danyau, who assisted Cazeaux in his case, reported a successful one of his own to the French Academy in 1851, where enucleation was performed. Mr. James Bell, surgeon, of Forres, in 1819, removed a fibroid obstructing labour, and his patient recovered. Mr. Rankin of Carlisle reported a case in 1850, where a fibroid had obstructed in several successive pregnancies, ultimately necessitating craniotomy; but after the last confinement, which was accomplished by turning, on the thirty-eighth day the mass came away; and Professor Goodsir, who examined it, pronounced it to be a common uterine fibroid. Simpson gives several cases where labour was terminated without enucleation. Dr. Montgomery and Dr. Shekleton performed Cæsareotomy under similar circumstances. Dr. Beatty of Dublin met with a case where the fibroid was of such magnitude that he thought Cæsarean section would be required; yet when labour came on he was able, by adopting Merriman's plan of pushing it up and fixing it above the brim, to allow the birth to be completed naturally. The practical indications to be followed out in such cases are (Burns) —

1. If the tumour be moveable, push it above the brim.
2. If immovable, interfere early and determine its nature by means of a trocar. When soft and not large, the forceps are to be applied; and when these fail, turning may be adopted.
3. Extirpate or enucleate in preference to the crotchet; but if the tumour be of large size, if there be extensive connections or danger from hæmorrhage, then do not attempt extirpation. If tapping had proved ineffectual in an early stage, then perforate and extract the child by means of the cephalotribe or crotchet as soon as circumstances will permit.
4. In extreme cases, where removal of the tumour is impossible, the Cæsarean section must be resorted to.

## CLINICAL MEMORANDA.

### ANEURISM OF THE ABDOMINAL AORTA, PRESENTING UNUSUAL FEATURES.\*

THE patient, an old soldier, aged 54, suffered much from abdominal and gastric pain and anæmia. On September 18th, 1868, gangrene of the right leg suddenly came on, and no pulsation could be felt in the external iliac artery, nor in any of the arteries of the limb. A line of demarcation speedily formed about three or four inches below the knee-

joint; and, although the impediment to the circulation was evidently high up, no further gangrene took place. The patient's health suffered less than was expected; and on December 19th (portions of the muscle, etc., having been previously removed from time to time) the bone was sawn through, and the leg removed as near the sound part as possible; but dead structures only were divided. The stump healed well, the projecting portion of dead bone coming away on April 6th, 1869; and the patient was able to move about tolerably freely with a wooden leg. During this time, the aneurism not only ceased to enlarge, but became smaller, more dense, and with lessened pulsation; the improvement being due probably to the diminished amount of blood circulating in the aorta, as well as to the rest and regimen. The secondary symptoms were also relieved. After a time, however, the aneurism again enlarged, and the patient died from exhaustion on November 5th, 1870, more than two years having elapsed since the gangrene came on; and during that time he suffered but little, the severe pains not returning when the tumour again enlarged. A *post mortem* examination showed that the aneurism had burst into the peritoneum by a valvular opening; a large quantity of clotted blood being found arranged in layers, and evidently deposited at different times.

Ramsgate, September 1871.

S. WOODMAN.

### EFFECTS OF BROMIDE OF POTASSIUM.

I HAVE seen bromide of potassium, in half-drachm doses twice daily, produce aphasia. The patient was a lad twenty years of age. After taking the drug for a fortnight, he said his memory was bad; and, on inquiry, I found that he called things by their wrong names, and very often forgot the name which he wanted to pronounce. His father thought it very stupid of him, and scolded him for it.

J. HADDON, M.D., M.A.

Eccles, Manchester, September 1871.

### WASP-STINGS. 2

I HAVE tried tincture of arnica this season in several cases which have come under my notice; and in each one the relief has been immediate, if had recourse to immediately after the reception of the poison. It is to be applied undiluted to the part affected by a large camel-hair brush; or, if its general application be necessary, from any additional inflammation from delay, I then recommend its dilution of one part to two or three of water.

JOHN FOSSE HARDING, F.R.C.S.

Tunbridge Wells, September 23rd, 1871.

## REPORTS

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### THE NOSOLOGY AND TREATMENT OF DIARRHŒA, CHOLERINE, AND ASIATIC CHOLERA.

GENERAL HOSPITAL, BIRMINGHAM.

DR. WADE thinks that, although diarrhœa is often directly traceable to the ingestion of some particular food, yet, as cases frequently happen without any apparent cause of this kind, and as we may often notice that medicines (e.g., tincture of rhubarb) will act on the bowels in doses which do not in ordinary times produce that effect, we must admit that summer diarrhœa is partly referable to what Sydenham, with judicious vagueness, termed an "epidemic constitution". An attempt to define the nature of this leads us into the realms of speculation. It is reasonable to suppose that elevation of temperature is an important, perhaps essential, element of it. It is possible that the effect of heat may be to intensify what Burdon Sanderson calls the zymotic power of water; and this may be the link which joins the external temperature to the autumnal disorder of the human system. Such a bare possibility justifies the practice of depriving water of its zymotic powers by such a simple method as the addition to it of Condy's fluid, when it is to be used for drinking purposes. Again, it is not improbable that heat may primarily affect the nervous system. Even this is not proven; still less certainly can we say what section (if any) of this system is the first to suffer. Assuming an ultimate (if not primary) disorder of the ganglionic system, we should be prepared to find differences in different cases or seasons in the amount or kind of derangement of various abdominal organs. Thus the action of the liver is by no means uniform; its secretion is sometimes at first diminished and afterwards increased, and *vice versa*. To these variations is perhaps due what we think we

\* Read before the East Kent District Meeting of the South Eastern Branch.

have observed; namely, that in some years nothing acts more speedily and satisfactorily than dilute sulphuric acid (B. Acid. sulph. dil. 3iij; aquæ fontis 3viij; M.), whilst in other years chalk and vegetable astringents seem more uniformly efficacious. Again, in some years there are many, in other years scarce any, cases of a dysenteric type. In some years cramps are a prominent symptom in most cases; in other years much less frequent and urgent. In some years cases are attended with much greater nervous depression and exhaustion (without actual collapse) than in others.

When a case is apparently to be traced to ingesta, there can be no doubt of the propriety of a dose of rhubarb or castor-oil: the addition to either of a few drops of laudanum often gives great comfort to the patient. Afterwards such astringents as a study of the epidemic of the year has shown to be most suitable are to be given.

In cases allied to dysentery, in place of ordinary astringents, a combination of turpentine, ipecacuanha, opium, and demulcents, will be found most efficacious. When there is much vomiting as well as purging, effervescing mixture with hydrocyanic acid, given every other hour, and a pill of acetate of lead and opium intermediately, will prove satisfactory. In such a case, as indeed in all of any severity, a warm bed is a great adjuvant to any treatment.

In the treatment of the diarrhoea of infancy, whey and barley-water should be at once substituted for milk or other food, and beef-tea should be avoided. Minute doses of stimulant are often needed. It seems a great pity that the term "lientery" should have been allowed to drop. It is a great fact that much of the diarrhoea of children is, in fact, an indigestion, more especially of caseine. This fact is, in practice, much overlooked, whereas the use of the term lientery would have kept it in mind (see a paper on Infantile Lientery, BRITISH MEDICAL JOURNAL, 1858). Such cases should be treated as dyspepsia; and chiefly by diet and alkalies, least of all by opium and astringents. There is probably no hard and fast line anywhere in the gradations between the mildest case of diarrhoea and the severest one of English cholera. If there be, we are not in a position to draw it.

Birmingham has never afforded an opportunity for studying an epidemic of Asiatic cholera. From observation of a few imported cases, it would appear that cases may occur in which there is a retention in the intestines of their secretions to an extent that embarrasses the patient. When this does occur, it is sound treatment to empty the bowels. This may be done, whatever notions we hold as to the propriety of an eliminant plan of treatment, under all circumstances. It would also appear that in collapse opium is useless at the time, and may be injurious subsequently; that brandy is useless, and indeed may be immediately injurious. The best treatment is external warmth, if agreeable to the patient, and as much simple diluent as he can take, at a temperature the most agreeable to himself.

#### MANCHESTER ROYAL INFIRMARY.

DR. HENRY BROWNE says that autumnal diarrhoea and English cholera are simply the consequences of different degrees of hepatic venous congestion. Asiatic cholera is a form of morbid poisoning.

Autumnal diarrhoea and English cholera may be very distinctively named from their symptoms, as bilious purging, and bilious vomiting and purging. The more severe form may be followed by collapse, cramps, and colourless motions, and it may even prove fatal, but never all at once. Asiatic cholera, omitting the premonitory loose painless motions, begins, and may end at once, in collapse; and the rice-water vomiting and purging are characteristically abilious.

As to treatment, a good warm bed best restores the circulation to the surface in excessive secretion of bile; and, the cause being thus removed, the effects soon pass away. Besides, the horizontal position soothes. Whatever share food may have had in the disturbance of function has been remedied by the beneficent symptoms; abstinence for a time is enforced, and only drinks are tolerated. Subsequently, to allow fats, but no sugars, is strictly scientific. Ten grains of the bicarbonate of soda, with five minims of tincture of capsicum, or thirty minims of tincture of ginger, and two drachms of tincture of rhubarb, in mint-water, are all the medicines that ordinary cases require. In the severest cases, ten minims of opium may be added, and the whole be repeated every two hours. Frictions and stimulants, as burnt brandy, may be used for cramps, and collapse.

When called to contend with Asiatic cholera, we know, too well, that we have to deal with a poison which we cannot neutralise. Yet we know that the evacuations contain the poison, and, therefore, we must consider the vomiting and purging to be beneficial actions, which we should aid rather than restrain. Dr. Browne is, therefore, an eliminationalist, although, in the last epidemic in Manchester, everything seemed to confirm the wisdom of treating the premonitory diarrhoea with opiates and astringents (because that was the only plan adopted).

Should the present, or any future, choleraic wave overtake him, he has determined to give elimination a fair trial, in all the stages of the disease. Still, he would prefer tincture of rhubarb and soda to castor-oil. Theoretically, cholagogues are indicated, or rather oxygen. And the saline treatment is certainly scientific, and according to common sense. The patient is very thirsty, from losses of the liquor sanguinis; therefore he should be allowed to drink freely of an artificial serum, only it should be more dilute than the true serum, that it may enter the vessels by physical laws, seeing the physiological are nearly in abeyance. This plan was adopted, at Dr. Browne's suggestion, in several of the cholera sheds in the last epidemic in Manchester. The formula was taken from Dr. G. O. Rees' analysis of the serum, only doubling the water. It was: Chloride of sodium, gr. xlij; bicarbonate of soda, gr. xxx; phosphate of soda, gr. xij; sulphate of soda, gr. vj; water, Oij. Mix for a drink, to be used *ad libitum*.

Lienteric diarrhoea, for which sulphuric acid is a specific; or mucous diarrhoea and dysentery, in which Heberden's sulphate of magnesia and ipecacuanha, with a laudanum and sheep's-broth enema, are indicated—cannot, of course, be confounded with bilious diarrhoea and cholera.

#### NEWCASTLE-UPON-TYNE INFIRMARY.

DR. PHILIPSON remarks that diarrhoea, severe and intractable, has been very common during the past few weeks; it being noticeable that many of the cases were of the bilious form, from acid or an increased secretion of bile, others being distinctly inflammatory in character. In the bilious variety, the evacuations were at first feculent, and commonly green or greenish-yellow, subsequently becoming more fluid and watery. If the diarrhoea continued, a greenish-yellow mucus was mixed with the feculent matter. In the inflammatory condition, the evacuations were watery and serous, and exhibited every shade from a dark-brownish or greenish-brown, to a pale greyish or whitish colour. Sometimes the discharges contained pieces of thick gelatinous mucus. In both, the whole system was relaxed and debilitated. A sudden chill, drinking cold beverages when the body was over-heated or perspiring, and exposure to the ardent solar heat, appeared to be the exciting causes. The bilious condition was best remedied by mercury with chalk, and the compound powder of ipecacuanha; while, in the inflammatory form, warmth to the surface, fomentations, demulcents in combination with small and frequently repeated doses of opium, proved of marked service.

#### BRISTOL GENERAL HOSPITAL.

DR. MARTYN individually inclines to the following conjectures.

*Autumnal diarrhoea* is a local irritation of some portion of the intestine, resulting in pain and purging, when undigested (chiefly non-nitrogenous) matters reach the point in question. The cause is not unlikely to be low forms of life developed in food at the autumnal season. The treatment, when the bowels are empty, should be to soothe. Chalk is the antacid which acts most directly in neutralising the irritating secretions and food-decompositions. He also gives catechu, opium, and logwood. Equally necessary, he thinks, is the abstinence from any food at all difficult of digestion.

*English cholera and Asiatic cholera* do not differ generically, but in degree of intensity. They depend on the presence of an unknown poison in the blood. Autumnal diarrhoea may, Dr. Martyn thinks, be related to cholera, as local tubercle is to acute tuberculosis, in which the poisonous matter, having overflowed the barriers of the lymphatic system, reaches the blood. The intestinal drain is an eliminating process, for the poison is found in the evacuations; but should not be encouraged, because, by the diminution and deterioration of the circulating fluid, death is necessarily approached. In the treatment of cholera, he relies at present on the free drinking of diluents, water chiefly; and the persistent effort to give artificial warmth to the surface of the body (except the spine). For the sake of the community at large, the disinfection of all emanations from the sick is imperative.

#### BRISTOL ROYAL INFIRMARY.

DR. E. LONG FOX says that autumnal diarrhoea can often only be distinguished from English cholera by its less intensity. There are no very distinctive symptoms. Both diseases seem to depend generally on atmospheric causes, by which the liver is over-stimulated; and food, which at other times is easily assimilated, becomes difficult of digestion. This hepatic disturbance is especially noticeable in autumnal diarrhoea. In this disease there is often a profuse discharge of bile, accompanied by vomiting, flatulent distension, and some gripping pain in the bowels. In children, particularly if the evacuations are stained with blood, he gives minute doses of castor-oil, with powdered acacia and dill-water, for twenty-four or forty-eight hours, or the formula that was in use sixteen years ago at the Great Ormond Street Hospital for Sick

Children, under the name of *mistura olei ricini*. The abdomen should be poulticed and the child kept in bed. If after two days the discharge persist, a little bismuth and chalk will often act well, without having recourse to the stronger astringents. In an adult, it is well to begin with one dose of castor-oil; and after the full action produced by the oil, he uses catechu and logwood, with opium if the pain be severe.

In English cholera the discharges are generally more mucous than in autumnal diarrhoea, the cramps more intense, attacking the limbs—the lower especially—as well as the bowels. The voice may be affected. (Dr. Fox has lately had a case in which it was almost lost.) There are much coldness of the surface, very violent vomiting, and great prostration. After a time, tenesmus may ensue. He gives one dose of castor-oil, if it can be kept down, and then trusts very much to lukewarm demulcent drinks. He does not think iced drinks good in cases of great prostration. When the vomiting is at all lessened, he gives Liebig's beef-tea as a stimulant rather than a nutriment, and strong black tea. External warmth is applied, all through the attack, to the abdomen; and sinapisms at first, also friction to limbs. After a certain point, a warm aromatic astringent is useful; and if tenesmus be present, a suppository of opium, or of opium with belladonna. In both diseases, rest in bed is most necessary.

#### ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

DR. LATHAM considers that autumnal diarrhoea may be caused either (1) by simple errors of diet, (2) by the effect of heat lessening the digestive powers, (3) by a larger amount of fruit or vegetables being taken with the food, or (4) by derangement of the biliary system induced by sudden changes of temperature, etc., and resulting in either a too abundant secretion or a lessened absorption of bile. As regards treatment, if the evacuations have been abundant and feculent, and there be no reason to suppose that the intestines contain undigested food, then the recumbent posture, bland food—such as boiled milk, arrowroot, etc.—must be prescribed; and, according to the circumstances of each case, either lime-water and milk, or some such draught as the following may be given every four or six hours: *Pulv. cretæ aromat. gr. xx—xxx; spiritus chloroformi mxv—xx; tincturæ opii mv—x; aquæ menth. piper. ʒiiss*, with or without *mxv—lx* of tincture of catechu. If, though the motions are loose and frequent, there be reason to suppose that the intestines still retain hardened feces or undigested food, then it is better to commence the treatment by giving five grains of compound ipecacuanha powder, with an equal quantity of hydragryum cum cretâ or a grain of calomel, and an hour afterwards a drachm of compound rhubarb powder. If after this has effected its purpose the diarrhoea and pain continue, the irritation may be soothed merely by the administration of fifteen or twenty drops of laudanum, or the mixture above prescribed may be given. In cholera—where in addition to diarrhoea we have severe cramps and violent vomitings—after the alimentary canal has been freely evacuated, and if remedies be not tolerated by the stomach, the hypodermic injection of morphia is speedy and reliable; but it must be borne in mind that, when it is administered in this way, narcotism is sometimes induced by an amount much smaller than may be given by the mouth without risk. A quarter of a grain may be injected, and repeated in an hour if necessary; its effects must be carefully watched; and if other doses be required, the intervals between must be sufficiently long to avoid the risk of inducing narcotism. The patient's intense thirst may be best relieved by giving small quantities of iced water, or small pieces of ice to swallow, at short intervals.

With regard to cholera, Dr. Latham maintains that in whatever way the poison may be introduced into the system, the disease is primarily and essentially a local affection of the mucous membrane of the intestines; and he considers that all the phenomena of the disease, including the condition of the blood, the failure of the heart's action, the cramps, the prostration, and collapse, may without difficulty be explained by the extent and severity of this primary local affection. The condition of the blood is simply a physical result of the copious serous evacuations: the thickened condition of the blood causes stagnation in the capillaries, and impeded flow of blood through the capillaries of the heart causes paralysis of that organ. This paralysis is produced also, and perhaps chiefly, by the depressing effect of the acute intestinal mischief on the sympathetic nerves, just as in poisoning by arsenic, or after perforation of the stomach or intestines, failure of the heart's action takes place, with loss of pulse and coldness of the extremities. The cramps are not peculiar to cholera, but occur equally in cholera, and are the result of reflex action, induced by the irritation in the intestines. Holding these views, Dr. Latham would treat the painless diarrhoea, which almost invariably precedes the fully developed attack of cholera, as characterised by rice-water evacuations, on the same principles as cholera. If, however, the diarrhoea increase, or the rice-

water evacuations show themselves, then the administration of morphia or opium must be discontinued; and no better treatment can be now recommended than that which Niemeyer found so useful in Magdeburg in 1848, and which Pfeuffer in 1854 recommended as being, in his opinion, the most successful. Niemeyer says: "In this stage, before the heart's action begins to fail, and the blood to be inspissated, I order for adults one grain of calomel every hour or every two hours, and envelope the abdomen in cloths well wrung out of ice-cold water. Let the cloth be renewed as soon as it gets warm—about every quarter of an hour or every half hour. If with this treatment the symptoms abate, especially the anxiety and oppression at the præcordia, the rolling about of the bowels, or the frequency of the evacuations, the interval between the renewal of the cold application may be gradually extended, so as to be repeated only every hour or every two hours." These ice-cold applications afford great relief; and "so soon as the damp cloth becomes even slightly warm, the patient will earnestly beg for a speedy change. If the calomel do not decidedly relieve the vomiting—as in many cases it will not—at once discontinue its use. I was often obliged to abstain from the administration of any medicines on account of the violent vomiting. In all cases, I allowed the patient to keep a piece of ice in the mouth; and besides, let him have small quantities of ice-cold water, containing a little white of egg, to drink. Tea, coffee, and all gelatinous or warm drinks, at this stage of the disease increase the anxiety, and the vomiting, etc., do not relieve the burning thirst." (*Die Symptomatische Behandlung der Cholera*. Magdeburg: 1849, p. 25.)

DR. BRADBURY is of opinion that cholera is only an aggravated form of autumnal diarrhoea, and that Asiatic cholera is a totally different disease, produced by the introduction into the system of a specific virus. He thinks that when an attack of diarrhoea is accompanied by constant vomiting, cramps, coldness of the surface of the body, great prostration of strength, and an extremely feeble pulse, such an attack should be called English cholera or cholera. When there are rice-water stools, rapid collapse, lividity of the face, feebleness of voice and a history of an epidemic, the case is one of Asiatic cholera.

In the treatment of simple diarrhoea, rest in bed and the withdrawal of all solid food for a day or two, restricting the patient to mutton broth and arrowroot and milk, generally suffice for a cure. When there is reason to believe that the diarrhoea depends upon some irritant in the bowels, a dose of castor-oil or tincture of rhubarb is the most efficacious treatment.

In the diarrhoea of children, not dependent upon teething or improper food, Dr. Bradbury finds the following mixture most useful.

*R. Tincturæ opii ʒj—j; acidi sulph. diluti ʒij—iij; syrupi aurantii ʒv; aquæ ad ʒss*. M. Sumatur ter quotidie.

This mixture has checked an attack of diarrhoea which had resisted the action of chalk, lime-water, etc., remedies which Dr. Bradbury prescribes when he believes the purging to depend on a too acid state of the intestinal secretions. A teaspoonful of sherry, given three or four times daily, is very beneficial in some cases of obstinate diarrhoea occurring in young children.

In cholera, the sickness is best relieved by iced soda water, and the cramps by hot bottles to the feet, and hot flannels to the legs and abdomen. The treatment in other respects should be the same as in autumnal diarrhoea, the rest in bed being especially insisted upon.

In Asiatic cholera the bowels should not, at any stage of the disease, be locked up by opium or astringents of any kind, and all alcoholic stimulants should be withheld. Judging from the efficacy of sulphurous acid in typhoid-fever (*vide* BRITISH MEDICAL JOURNAL, Dec. 3rd, 1870, p. 599), and from the similar mode of propagation, etc. (*vide* Parkes' *Practical Hygiene*, second edition, p. 449), of that disease and Asiatic cholera, Dr. Bradbury thinks the sulphites or hyposulphites of soda or magnesia, or a solution of sulphurous acid, are deserving of a fair trial in the latter disease.

#### EAST SUFFOLK AND IPSWICH HOSPITAL.

DR. C. M. DURRANT says that the usual autumnal diarrhoea has been both prevalent and severe, and it is still very much so in the neighbourhood of Ipswich. The symptoms are general *malaise*, with flatulent distension of the abdomen prior to the setting in of diarrhoea, which has been accompanied by an unusual amount of abdominal pain. If seen early, a rhubarb and magnesia draught has been useful, and he has found no medicine for adults so serviceable as carbonate of ammonia, soda, chloric ether, in small doses (five minims), and tincture of opium. In the diarrhoea of children, the sulphuric acid has given most satisfaction, with or without laudanum. In one very severe case of English cholera, with rice-water evacuations, and great prostration and coldness, Dr. Durrant gave castor-oil, and also the ammonia mixture. The case ultimately did well.

In reference to the distinctiveness of the three varieties, he believes that the strictly premonitory symptoms of each are almost identical.

#### ST. THOMAS'S HOSPITAL.

In the opinion of Dr. CLAPTON, Asiatic cholera and autumnal diarrhoea are distinct and specific diseases, but not so choleraic diarrhoea or English cholera. This term appears to have been given indiscriminately to severe forms of diarrhoea and to mild forms of cholera. Such cases are very numerous during cholera epidemics. Ordinary diarrhoea is at such times apt to take on a choleraic type; just as, when typhus is rife, all febrile affections are apt to assume a typhic type; and, when influenza is epidemic, catarrhal affections generally acquire its particular characters.

Simple diarrhoea never drifts on to Asiatic cholera (which is a specific disease, produced by a specific cause), but strongly predisposes the patient to its attack, especially if it have continued unchecked for some time.

The most reliable distinctive marks between autumnal diarrhoea, English cholera, and Asiatic cholera, are the following. In diarrhoea, the face is pallid, but there is nothing characteristic about the features; there is not much constitutional disturbance, except in the severer forms; nausea and occasional griping pain are complained of; the stools are chiefly bilious. In English cholera, the face is indicative of much distress. At the onset, there is considerable griping and uneasiness about the abdomen; but the subsequent stages are generally attended with little or no abdominal pain. The other symptoms are, vomiting; thirst; tongue furred and flabby, but not cold; pulse rapid and feeble; stools chiefly mucous: in the severer cases, serous stools, cramps, hiccup, and intense prostration. In Asiatic cholera, we find sharp features, sunken eyes, and a general leaden hue of the skin; vox choleraica; cold tongue; thready pulse; vomiting; stools serous (rice-water); no griping pain, but severe cramps, affecting chiefly the abdominal muscles and the calves of the legs; suppression of urine; and a strong tendency to collapse and death.

With regard to treatment, simple diarrhoea, unless of a severe character, scarcely requires any medicinal interference. Rest, and plain, nutritious, unstimulating food, are generally all that is necessary; but, during cholera outbreaks, every case, however mild, should be carefully attended to. As it mostly arises from some error in diet, and is attended with very acrid secretions and an excess of bile, an aperient is obviously indicated at the onset, such as a dose of castor-oil or rhubarb. If the griping pain be very great, a few drops of laudanum may be added. Saline aperients are to be particularly avoided. Should the diarrhoea continue, it will be necessary to prescribe astringents, as catechu or rhatany; absorbents, as chalk or bismuth; and perhaps also an opiate, to soothe the morbid irritation of the nerves.

Dr. Clapton's experience of the treatment of Asiatic cholera is chiefly derived from the epidemic of 1854, at which time 208 patients were admitted into the cholera wards of St. Thomas's Hospital. They were all watched day and night by Mr. Whitfield and himself, and full notes were taken of each case. There were 67 deaths and 141 recoveries. On referring to these records, he finds that the general and most successful plan of treatment was the hot-air bath at 130 deg.; large mustard poultices to the abdomen and calves of the legs; an ipecacuanha emetic; ice *ad libitum*; iced soda water. As soon as the patient could take food, a little milk, arrowroot, or weak beef-tea, was given. In very few cases were stimulants or opiates prescribed. The ipecacuanha emetic in many instances quickly brought about reaction from the state of collapse, and gave an impulse to the heart's action. Castor-oil, in frequent half-ounce doses, was given in ten consecutive cases; but six died, and the plan was at once abandoned. Those treated by calomel in frequent doses also presented a large mortality—fifteen deaths out of twenty cases so treated. Creasote, in half-hour doses of one drop, was given to six patients, who were also treated by hot-air bath, emetic, ice, and mustard poultices: five recovered. Quinine, in large and frequent doses, was given in two cases: one recovered. In nearly all the less severe cases of cholera, diluted sulphuric acid in half-drachm doses every two hours was prescribed, in addition to the other means explained. In these cases, the mortality was only one-sixth; but that might have been from the comparative mildness of the attacks.

Choleraic diarrhoea or cholera was found to be most successfully treated by commencing with the following draught: R Tincturæ rhei ʒss; tincturæ opii mx; spiritus ammoniæ aromatici ʒj; tincturæ zingiberis ʒss; aquæ menthæ piperitæ ʒij. Afterwards the following was given every two hours: R Acidi sulphurici diluti ʒss; tincturæ cardamomi compositæ ʒj; aquæ menthæ piperitæ ʒiss. Simple farinaceous food was allowed, with weak tea or broth, and in some cases a little brandy. Absolute repose in bed should be enjoined in every case.

#### SEAMAN'S INFIRMARY, RAMSGATE.

##### SURGICAL CASES.\*

(Under the care of Mr. R. HICKS.)

*Popliteal Aneurism cured by Flexion aided by Intermittent Compression.*—John Foad, aged 35, a miller, was admitted into the Infirmary on April 3rd, with a large pulsating tumour in the left popliteal space. He had been complaining, for about five weeks, of what he supposed to be rheumatism; and both legs were much swollen and inflamed. There was no disease of the artery in the right leg. He had discontinued work (lifting heavy sacks of flour) a fortnight. On admission, he was found to have in the left popliteal space a large pulsating tumour, measuring nineteen inches in circumference. The walls on the inner side were so thin, that fears were entertained that the aneurism would burst. He was placed in bed with the leg firmly flexed on the thigh, and Signoroni's tourniquet was placed on the femoral artery in Scarpa's triangle. As there were no relays of dressers to superintend, an ink mark was made where the tourniquet was to be applied, and the patient was instructed how to do it. He bore the first application for more than an hour, and after a short rest applied it again. On the 10th the measurement was eighteen inches and a half, and the instrument was borne longer and applied more frequently. During the night it was not applied throughout. On the 16th the circumference was eighteen inches; and on this day the pulsation, which had gradually been becoming fainter, ceased. The size of the tumour gradually decreased, and the swelling rapidly went down as the leg became more fit for use, and the compensatory circulation established. He can now walk with the aid of a stick, but is not able to completely straighten the leg. In consequence of the constrained position of the leg, both knee and ankle-joints are stiff; there is also contraction in the old aneurismal sac; but these conditions are improving day by day, and, in a short time, there is little doubt that perfect use of the leg will be regained. [The patient was exhibited.]

*Fractures of the Skull.*—William Gibbens, aged 31, was admitted on January 7th, 1871. Whilst he was heaving the trawl, the handle of the capstan flew back and struck him on the top of the head. He was found to have sustained a comminuted fracture of the skull, with depression and severe scalp-wound. A large lock of hair was firmly wedged in the fracture, and required considerable force to extricate it. He was perfectly conscious and had no general symptoms, beyond a slight loss of power of the right upper extremity. I therefore decided to leave the wound open and wait for symptoms of compression; none, however, occurred, but the whole of the bone involved was gradually thrown off and removed piecemeal by the dressing forceps. Five portions were so taken out, measuring two and a half inches by three-fourths of an inch when placed together. Only a very small portion of the inner table came away. In April the patient was quite well, and able to resume his occupation. The fracture was slightly to the left of the median line on the frontal bone.

Emma Palmer, aged 36, in a fit of jealousy, threw herself over the cliff (a height of sixty feet) and fell on the chalk beneath, which was covered with about a foot of water. She was unconscious for about two hours. She bled from the nose and ears, but no cerebro-spinal fluid was seen. She had sustained a fracture of the right parietal bone, which could be traced the whole length of the scalp-wound, which was three inches long. It probably extended much further; the left radius was fractured close to the wrist-joint, and she was literally a mass of bruises. The arm was placed in a pistol-splint, and ice applied to the head. She progressed favourably until the seventh day, when the right eyeball began to be pushed out, and was eventually completely protruded and destroyed. The introduction of a very small trocar and cannula showed that bleeding into the orbit had been the cause. She is now making a rapid recovery, with the loss of the right eye. The case is interesting, in consequence of the protrusion and rapid destruction of the right eyeball coming on at the seventh day; the right eye, on admission, being quite healthy, the pupil acting, and no symptom of any kind indicating anything wrong.

*Successful Skin-Transplanting on an Ulcer of Five Years' Standing.*—John P. contracted syphilis six years ago; five years ago an ulcer formed over the right external malleolus. He went into one or two hospitals, and sometimes the ulcer nearly healed and then became as bad as ever. He came under my care in the latter end of last year. No disease of the bone could be detected; and after trying rest and stimulating lotions with constitutional treatment, without any improvement, I scraped some epithelial scales and placed them on the ulcer, covering the part from the air. This had no good effect. I then took a small

\* Read before the East Kent Meeting of the South Eastern Branch.

piece of skin from the arm, and placed that on some scratches made on the raw surface. The wound soon took healthy action and healed to half its size; but beyond that it would not go. Finding the tissues very tense all round, I made four free incisions around the circumference; thereon the ulcer rapidly healed, and has remained quite sound until now, nearly six months.

**Hernia Operations in Aged Persons.**—Mary Goldsmith, aged 75, was admitted on July 4th, 1870, with strangulated inguinal hernia of two days' standing. The taxis under chloroform being unsuccessful, the ordinary operation was performed; the sac being opened, and she was discharged cured on July 18th, fourteen days after the operation.—Mary Rolfe, aged 76, had had strangulated inguinal hernia two days. The sac was opened in operating. She was admitted December 15th, 1870, and discharged cured January 12th, 1871.

## LIVERPOOL ROYAL INFIRMARY.

### EXCISION OF THE TONGUE.

By REGINALD HARRISON, F.R.C.S., Assistant-Surgeon to the Infirmary.

J. T., an engineer, was admitted into the Liverpool Royal Infirmary, under my care, in August last, for epithelioma of the tongue of some duration. The case was deemed favourable for operation, the disease being limited to the anterior lateral portion of the organ, the adjacent glands being free, and the general health of the patient good. A small portion of the tongue had been excised before the patient came to Liverpool, by the surgeon under whose care he had previously been; but the disease had returned. The posterior half of the tongue was soft and apparently free from disease; and it was, therefore, determined to extirpate the whole of the organ, after the manner which has been successfully practised by Mr. Bickersteth.

On August 22nd, the patient being seated in a dentist's chair, and chloroform having been fully administered, I seized the tongue with a vulsellum, and divided the frænum and adjoining mucous membrane, so as to permit the organ to be more thoroughly drawn forward. I then passed a narrow knife from about an inch below the symphysis of the jaw through the floor of the mouth. Through this opening, by means of an eye-probe with a piece of thin tape attached, I drew the wire of the *érasaur*. The tongue being well drawn forward, I passed the loop of the *érasaur* back with the fingers of the left hand, so as to include the whole of the organ. While the wire was being tightened, I prevented it from slipping forward by my left fingers until a groove had been formed. The screw of the *érasaur* was very gradually turned, exactly thirty minutes elapsing before amputation was completed.

The patient was kept under the influence of chloroform during the whole time, and he afterwards told me that he had experienced no pain whatever. There was no blood lost either during the operation or afterwards, a little frothy mucus tinged with blood only requiring removal. I examined the stump, to see if I could find any vessel requiring a ligature; but the *érasaur* had done its work so well, that nothing like an artery could be discerned.

The patient made an excellent recovery, and left the Infirmary on September 1st, 1871. Nutrient enemata were regularly and frequently administered, until he was able to take a sufficiency of nourishment by the mouth.

I believe that the plan here described will be found the best for removing the whole of the tongue. As far as I have seen, the removal is quite as complete as where division of the symphysis is resorted to.

I am indebted to Mr. Stubbs and Mr. Hakes for their assistance at the operation.

## THERAPEUTIC RECORD.

**TREATMENT OF CHLOROSIS.** M. Delioix de Savignac proposes, in the *Bulletin de Thérapeutique*, the following formula as being likely to fulfil most completely the ordinary indications of treatment in chlorosis: tartrate of iron and potash, ten grammes; powdered aloes, two grammes; powdered castor, two grammes; powdered saffron, one gramme; to be made into a mass with Venice turpentine and divided into a hundred pills. At first, three pills are to be given daily, and the number is to be gradually increased to six or nine; care being taken to maintain a free action of the bowels without producing diarrhoea. The pills are to be taken three times daily; early in the morning, and at luncheon and dinner. M. Delioix de Savignac explains that the aloes is intended to obviate the constipation frequently met with in chlorotic patients; the castor-oil and saffron to relieve flatulent distension of the abdomen; while

the turpentine exercises a beneficial influence on the leucorrhœa. If the aloes act too energetically, it may be replaced by rhubarb; or, if the constipation remain obstinate, a little jalap, scammony, or gamboge may be added. If the bowels be already free, M. Delioix omits the purgative altogether. When the turpentine produces gastric disorder, or colic with or without diarrhoea, balsam of Peru may be substituted for it. The use of the pills is contraindicated in chlorosis attended with menorrhagia.

**MERCURIAL INUNCTION IN SYPHILIS.**—Professor Sigmund of Vienna, the leading authority in his country, has published a series of lectures in the *Wien. Medicinische Presse*. He discredits "latent syphilis". It shows always cutaneous or mucous signs when present. Abortive or prophylactic treatment he considers useless; but when the skin, mucous membrane, or glands, are involved, he has recourse to frictions with Neapolitan ointment. He recommends, to soften the skin, baths, and even vapour baths; careful attention to the cleanliness of the buccal and nasal cavities. The patient should then, if possible, apply the frictions himself: a drachm of the ointment is to be rubbed for a quarter to half an hour in the morning on the legs, thighs, arms, belly or chest; avoiding parts covered with hair. When another person makes the frictions, he should wear an oiled or India-rubber glove. The parts rubbed are not to be washed, but the personal and bed-linen must be frequently changed. On an average from twenty to thirty frictions are required. The treatment may, if desirable, be alternated or combined with alkaline or sulphurous baths. He generally continues it to the date of cure, and for one-third of its then duration after the cure.

**TREATMENT OF SCABIES.**—Monti (*Jahrbuch der Kinderheilk.*, iv, 2) has tried the effects of copaiba and of carbolic acid in cases of scabies in children. Copaiba produces on the tender skin violent burning and redness; these symptoms, however, disappear in half an hour. The itching usually disappears after the first inunction; and the effervescence ceases after three or four applications. The remedy has no further influence on the eczema. Better results have followed the application of carbolic acid (one drachm to a pint of water or to four ounces of lard). By the diligent rubbing of the affected part with this three times a day, the itch is usually cured in three or four days.

**AMPUTATION OF THE PENIS BY THE GALVANIC CAUTERY.**—Dr. J. Zielewicz writes on this subject in the twelfth volume of Langenbeck's *Archiv für Klin. Chirurg.* To thirty-three cases described by previous authors, he adds ten operations performed in the hospital at Breslau, and seven in his private practice; and arrives at the following conclusions. 1. Amputation of the penis was in almost all the fifty cases required on account of cancer; once for gangrene, and once for enormous vegetations. 2. Eight of the patients died—four at Breslau, from pyæmia. The danger of pyæmic infection does not lie only in the laxity of the areolar tissue of the penis, or in the veins of the bladder and prostate, but depends also, and perhaps especially, on the hospital atmosphere. In fact, in cases treated in private dwellings, there have been no deaths. The galvano-caustic method does not absolutely prevent the occurrence of pyæmia in any case, especially when the disease has once appeared in the hospital; but the operation diminishes the danger by not being attended with the hæmorrhage which follows the use of the knife. 3. Secondary hæmorrhage was not met with in any of the cases, in spite of frequent manipulation in the course of passing the catheter, etc. 4. The operation is not followed by traumatic fever. 5. Of forty-five cases where the ages were known, the ages in thirty varied from 40 to 60; the youngest patient was 26 years old, and the oldest 78. 6. The contraction of the urethral orifice seems to follow alike all operations for the removal of the penis.—Dr. Fischer, in a postscript to the paper, says that he has amputated by the galvanic cautery for carcinoma in three patients aged 52, 81, and 45 years. The first two patients recovered; the third, who was in very impaired health, died of pyæmia.

**TREATMENT OF NÆVUS BY THE GALVANIC CAUTERY.**—Dr. Maas of Breslau has collected in the *Archiv für Klinische Chirurgie* (vol. xii) the histories of 112 cases of nævus treated by the galvanic cautery. The results were as follow: *Capillary nævus*—cured, 32; improved, 1; result unknown, 1. *Cavernous or venous nævus*—cured, 72; improved, 8; result unknown, 1; died, 3. *Arterial or racemose nævus*—cured, 2; improved, 1. *Nævus combined with other tumours*—cured, 6; improved, 1; result unknown, 2. He derives from the examination of the cases the conclusion that the galvanic cautery is followed by the best results in nævus, and is much safer than the injection of perchloride of iron or any other coagulating fluid. It would, however, be wrong to say positively that the remedy is indicated in all cases of

*nævus*. As Virchow has well remarked, the surgeon must take the circumstances of each case into consideration. The battery used in the cases referred to was that of Middeldorpf.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, SEPTEMBER 30TH, 1871.

### DYNAMICS OF NERVE AND MUSCLE.

#### II.

IN a previous article (July 22nd, 1871) we noticed some very interesting and instructive views regarding the electrical properties of nerve and muscle, which have been advanced by Dr. Radcliffe in his able work on the *Dynamics of Nerve and Muscle* (Macmillan and Co., 1871). We inquired into the facts upon which Dr. Radcliffe has based his Leyden jar hypothesis regarding the electricity of muscle and nerve. We explained that for the maintenance of this hypothesis it is essential that the sarcous and nervous elements be surrounded by a non-conductor, which shall correspond to the glass of the Leyden jar. This non-conductor or dielectric Dr. Radcliffe finds in the nerve-sheath and sarcolemma. He has no direct proof that these are such bad conductors that they may act as dielectrics; but he tells us that he has investigated the conducting power of the fresh ligamentum nuchæ, and, finding this to be a very bad conductor, he has no doubt that the sarcolemma and nerve-sheath—seeing that they are chemically like the tissue of the ligamentum nuchæ—must be bad conductors too; sufficiently bad to play the part of the glass of a Leyden jar.

We are perfectly willing to admit that Dr. Radcliffe has been most ingenious in showing that if he take a "wooden cylinder, covered at its sides with a coating made of two layers of tinfoil, with an intermediate layer of gutta-percha sheeting" (p. 2a), and charge the outer layer of tinfoil with electricity, he can obtain many of the electrical phenomena presented by muscle and nerve; but we wish we had better evidence to the effect that a nerve-sheath or sarcolemma saturated with the saline juices that penetrate these, in order to nourish the contained tissue, is a sufficiently bad conductor to play the part of the glass of the Leyden jar, or the gutta-percha of the tinfoil model. Nay, more, we should indeed desire better proof of the existence of something like a dielectric membrane around non-striped muscular fibres and the striated fibres of the heart. If Dr. Radcliffe fail to show that such a membrane is found around these, we are at a loss to see how his hypothesis can be maintained. Dr. Radcliffe doubtless feels this himself; and we are glad to see that in his reply (BRIT. MED. JOURNAL, August 5th, 1871) to our first article, he endeavours to dispose of our objection. He says that the fibres of involuntary muscle "consist of a number of contractile cells imbedded in an amorphous transparent substance. They have no proper sheath or sarcolemma like the fibres of voluntary muscle. But what of this? The cell, there is every reason to believe, is the contractile part of the fibre. Its wall, in the opinion of many, takes the place of the sarcolemma—being, in fact, analogous to the sarcolemma; and certainly there is no reason why the contents should not be regarded as analogous to the contents of the sarcolemma. In point of fact, there is no good reason why these walls—if there be any walls—together with the amorphous transparent substance of the fibre outside them, should not be a crude, thick, less elaborated, sarcolemma". We confess ourselves unable to follow Dr. Radcliffe through all this. We are at a loss to know what he means by the cells of which he speaks in

connection with the non-striped muscular fibre; and we should be glad to know who are the "many" who hold that the "walls" of the non-striped muscle-cells are "analogous to the sarcolemma". We are not aware that any histologist has demonstrated anything at all corresponding to a sarcolemma around the sarcous substance of the non-striped muscular fibre, or around the sarcous substance of the striped muscle of the heart. We still think, therefore, that our objection has not been surmounted. After pointing out this unfortunate hiatus in the conditions necessary for Radcliffe's hypothesis, we commented on Du Bois-Reymond's views on the matter, and stated our conviction that his hypothesis is in harmony with the known facts of the case. As was pointed out by Du Bois-Reymond, the action of a muscle or a nerve is accompanied by a diminution of the currents which may be obtained from these tissues. Radcliffe and Matteucci maintain that this diminution of electricity is due to the escape or discharge of electricity from the tissue. Du Bois-Reymond, on the other hand, maintained that it is not due to discharge, but merely to a partial rotation of the intimate particles of the muscle and nerve, whereby the positive poles comes into contact with the negative poles of neighbouring particles, and their currents are in this way short-circuited. In our former article we pointed out what appears to us to be a failure in the evidence, that there is a discharge in the case referred to. Dr. Radcliffe replies that his observations, with the aid of Sir William Thomson's new quadrant electrometer, have furnished "the very *experimentum crucis* of discharge, because this instrument takes cognisance not of changes of current, but of the simple fact of charge and discharge".

Dr. Radcliffe deserves credit for having been the first to use this valuable instrument in researches on animal electricity. It does not appear to us, however, that it has enabled him to settle in his favour the question at issue. He finds by means of this instrument that the electrical tension of (e.g.) the longitudinal surface of a muscular fibre is less during action of the fibre than it is during the state of rest; and, seeing that he had previously pinned his faith to the notion that the fibre resembles a Leyden jar, he concludes that this diminished tension must be evidence of the discharge of electricity. But, supposing that we do not adopt the Leyden jar hypothesis at all, we then find little difficulty in accounting for the fact shown by the electrometer. The fact may be explained on Du Bois-Reymond's as well as Dr. Radcliffe's hypothesis. The short circuiting of currents inside the muscular fibre during the muscular contraction seems to us to account for the phenomenon shown by the electrometer, just as well as the "torpedo-like discharge" of the electricity. We conclude, therefore, that this "*experimentum crucis*" with the electrometer entirely fails to prove the occurrence of discharge of electricity when a muscular fibre is thrown into contraction.

Why does a muscle contract? is a question for which physiologists have been driven to their wits' end to find an answer. Gladly indeed would they hail a satisfactory solution of the difficult problem. Dr. Radcliffe offers a solution which demands attention. He says (*ib. cit.*, p. 98): "1. That the state of relaxation is brought about by the charges of electricity present in the muscle during the state of rest, the mutual attraction of the opposite electricities disposed on the two surfaces of the sheaths of the fibres elongating the fibres by compressing the sheaths at right angles to their surface; 2. That the state of contraction is caused by the discharge of the electricity present during the state of rest, the discharge leaving the fibres free, to return by virtue of their elasticity from the state of elongation into which they had been forced by the charge." Here is a view which is simple, and one which in its less perfect shape, as advanced by Dr. Radcliffe some years ago, has appeared so satisfactory to some physiologists, that they have adopted it as the explanation of muscular action. Dr. Radcliffe supports his theory by arguments based not only upon his views regarding the static nature of the electricity in muscle and its torpedo-like discharge when the muscle contracts, but also upon an ingenious experiment devised by him. He takes a flattened band of India-rubber to represent the elastic muscle. He partially covers both its surfaces with gold-leaf, and then charges one of the metallic surfaces with static elec-

tricity. The India-rubber fibre elongates, because, as he says, the communicated charge induces an opposite charge in the other metallic surface of the band. The opposite electricities attract each other; and in consequence of this the intervening India-rubber is compressed, and so elongated. On discharging the electricity, the band returns to its original dimensions. Dr. Radcliffe says (p. 102) that "it is scarcely too much to take this experiment as in itself a sufficient reason for removing the view of muscular action which is here adopted provisionally (the electrical view) from the region of pure speculation into that of actual demonstration." We wish that we could see the matter in this satisfactory light. We have failed to find all the conditions necessary for the Leyden-jar hypothesis. We have failed to find evidence that there is a discharge of electricity when a muscle contracts. Failing to find the proof of these being real events, we cannot, of course, adopt the theory of muscular action in which it is essential that they figure. But we go further; for we feel obliged to say that, even had the charge and discharge been proven, difficulties which seem to us insurmountable bar the way to our accepting this theory regarding muscle-action. 1. In this experiment, a piece of India-rubber is compressed by the attraction between two kinds of electricity upon its opposite surfaces. To us it appears that the sarcolemma, and not the sarcoous substance of the muscular fibre, corresponds to the piece of India-rubber; for it is the sarcolemma which, according to Radcliffe, separates the two kinds of electricity in the muscular fibres. It would seem, therefore, that the elongation and contraction of the sarcolemma must be regarded as the mainspring of muscle-action; and that the sarcoous substance has little to do but generate electricity when it is wanted, in order to compress the sarcolemma! Pity the contractile protoplasm which has not a sarcolemma or some such membrane around it! 2. If a discharge of electricity from a muscular fibre be essential for its contraction, it follows that a state of charge must not obtain to its full extent, at any rate, during the contraction of the fibre. But it has been shown by Helmholtz and Bernstein that the negative variation of the muscle-current (Radcliffe's discharge), which takes place when a muscle is stimulated, does not occur during the contraction of the muscle, but during the short interval intervening between the stimulation of muscle and the muscular movement. This is a point which has been overlooked by Dr. Radcliffe. We see no reason for doubting the accuracy of observers so thoroughly competent as those we have mentioned; and therefore, were the "torpedo-like discharge" true, we should have to say something like this. An almost momentary discharge of electricity takes place from a living muscle immediately after its stimulation; but, before the muscular contraction sets in, the muscle has again become charged with electricity, and remains so charged during its period of contraction. Here are difficulties indeed. It seems to us that we have adduced enough to show that Dr. Radcliffe's theory of contraction is untenable. It is true, as Dr. Radcliffe says (*BRITISH MEDICAL JOURNAL*, *loc. cit.*) that, while Du Bois-Reymond's hypothesis finds nothing for the electricity in muscle to do, his view assigns to it some useful work—to wit, the elongation of the muscular fibres; but we fear that even yet we must confess our inability to find anything for the electricity to perform.

Lack of space prevents our pursuing this subject further. We have not by any means alluded to all the topics treated of by Dr. Radcliffe in his interesting work. We advise all who are interested in questions relating to muscle and nerve to procure and peruse his ingenious work. Though we have been obliged to oppose some of the physiological doctrines which it contains, we nevertheless entertain for the author the highest respect. We heartily wish that we saw a greater number of accomplished physicians like Dr. Radcliffe striving to advance physiological science. The worrying work of an extensive practice, indeed, renders it difficult for any one to find time for such labour; and it is to be counted to the honour of Dr. Radcliffe, that he should have found leisure to labour at so recondite a subject. Where there's a will there's a way.

THE *Court Journal* describes her Majesty as still suffering from slight rheumatism of the foot. She did not leave her apartments for several days this week.

THE Introductory Address at the Liverpool Royal Infirmary School of Medicine will be delivered on Tuesday, October 3rd, at 3 P.M., instead of Monday, the 2nd, as previously announced.

MR. J. A. DOOD, of Balkail House, Glenluce, Wigtonshire, has kindly forwarded fifty brace of birds for the use of the patients at Guy's Hospital.

A PHLEBITE is by no means so trifling a complaint as the sound of the word suggests; and if M. Gambetta is really suffering from inflammation of the veins of the leg (phlebitis) which rumour inflicts upon him, he is the prey to a very painful disease.

DURING the recent epidemic of typhus in Vienna, 1766 patients were treated for the disease in the hospitals of the city during the twenty-one weeks from March 22nd to August 15th. Of these 366 died, giving a mortality of 22.12 per cent.

THE Government of India have resolved to organise a statistical department for the purpose of ascertaining and conserving the internal resources of India. Dr. Hunter will be the first Director-General of this new department.

THE mortality in Paris last week amounted to 832 deaths, of which 55 were from diarrhoea, 45 from bronchitis, 35 from dysentery, 17 from infantile cholera, and 2 from cholera. The general condition of the health of the city was good.

THE fatal cases of small-pox in London, which in the two previous weeks had been 81 and 57, rose again last week to 89, which were 73 above the corrected average number in the corresponding week of the ten years 1861-70.

HER Majesty the Queen has again shown her especial patronage of the Earlswood Asylum for Idiots, by presenting the sum of five hundred guineas, to entitle her Majesty to the presentation of a second child to the Asylum during her Majesty's life.

WE are requested by the Dean of St. Mary's Hospital to supply a previous omission by stating that a *conversazione* will be held in the Board Room of the hospital at the conclusion of the opening address, which will be delivered by Dr. Alfred Meadows in the Anatomical Theatre of the School at 8 P.M. on Monday next, October 2nd.

A TELEGRAM from Alexandria states that the Board of Health has ordered ten days' quarantine for steamers arriving from Constantinople, in consequence of the outbreak of cholera in that city. The days occupied in the passage will be reckoned in the case of steamers carrying a doctor.

Cholera is raging along the whole Arab coast, brought down, it is said, by the Turkish troops. The crews of our gun-boats have suffered from the scourge, as well as from the heat—to face which, indeed, according to all accounts, the vessels placed by the Admiralty at the disposal of the Indian authorities seem quite unfitted.

THE deaths from diarrhoea in London, which in the four previous weeks had been 487, 353, 293, and 268, further declined last week to 205, of which 186 were of infants under two years of age. Only two deaths were referred to cholera and choleraic diarrhoea last week, while in the eight previous weeks they had averaged 22. Both those last week were certified as choleraic diarrhoea, one of a child aged 2 years, and the other of a female aged 48 years.

ACCORDING to official returns, there are in Austria 4664 physicians, 3376 surgeons, 11759 midwives, 2248 apothecaries, and 6093 other persons in the sanitary service.

#### NEW INFIRMARY AT LAUNCESTON.

THE Rowe Dispensary at Launceston is about to be developed into a small Infirmary, containing six beds and an accident-ward. The new building is being erected at the expense of Lady Rowe, widow of Sir W. Rowe, late Chief Justice of Ceylon, to whose liberality the institution of the Dispensary is due.

#### A CASE OF ANEURISM OF THE INNOMINATE ARTERY.

A CASE of aneurism at the root of the neck—supposed to be of the innominate artery—in a female aged 45, has recently been treated at this Hospital by simultaneous ligature of the common carotid and subclavian arteries. The operation was performed on September 20th by Mr. James Lane, who tied the carotid artery above the omo-hyoid muscle and the subclavian beyond the scalenus. No unfavourable symptoms of any kind have resulted from the operation. The tumour appears to have diminished slightly both in size and in the strength of its pulsations.

#### MEDICAL OFFICER OF HEALTH FOR ISLINGTON.

At a special meeting of the Sanitary Committee of the Vestry of Islington, held at the Vestry Hall on Monday evening, the 25th instant—Dr. Harvey in the Chair—the eleven candidates selected out of the twenty-six for this office at the previous meeting on the 18th instant attended, according to request, and were personally examined before the Committee as to their fitness for the office. The result was that Mr. Haviland, Dr. Corfield, and Dr. Tidy, were the three recommended to the Vestry at large as the most eligible. The election is fixed for Friday, October 6th, at 8 P.M., and the electors have an *embarras de richesses*.

#### AN UNFORTUNATE ERRATUM.

IN the BRITISH MEDICAL JOURNAL of last week the printers erroneously transformed Dr. Mac Donald, F.R.S., the gentleman whom we mentioned as the probable professor of naval medicine at Netley, into Dr. Mac Donald Fox. To this erratum we call the attention of the editor of one of our weekly medical contemporaries, who, to the favour of continuous criticism of our doings and sayings, adds the compliment of the general appropriation of what pleases him of the contents of our pages in a very unceremonious fashion. We regret that this particular paragraph was ear-marked, and protest that the erratum was unintentional.

#### THE EFFICACY OF VACCINATION.

As it is not practicable to obtain direct experimental proof in England of the protective power of vaccination against small-pox, Dr. De Renzy quotes the following interesting fact from his experience.

"The priest of the Mahomedan shrine of Bahawal Hug, at Mooltan, Mukdum Shah Mahomed, consented, at the request of the Deputy Commissioner General Van Cortlandt, C.B., to have his son vaccinated; and I performed the operation myself, hoping that the example set by this high religious authority would have a good effect in inducing other Mussulman parents to allow me to vaccinate their children. The priest, indeed, had little faith in my assertions of the efficacy of vaccination; but, as he thought it could do no harm, he yielded, from a feeling of courtesy to General Van Cortlandt, so far as to have the child operated on. In due course, and some time afterwards, the ceremony of inoculation, which had been practised for many ages in the Mukdum's family, came to be performed; and then, to his surprise, he discovered that the boy would not take small-pox. The most skilful inoculators tried and failed to produce the disease. The experiment satisfied the Mukdum of the truth of what I had told him—that vaccination, properly performed, is an almost sure preventive of small-pox. The boy is now himself the priest of the shrine of Bahawal Hug, his father having died two years ago. Unlike his father, who was deeply pitted with small-pox, he does not bear the smallest trace of that terrible disease."

#### THE HAMPSTEAD SMALL-POX HOSPITAL.

THE Hampstead Small-pox Hospital inquiry threatens to assume proportions not much inferior to those of the Tichborne case. It is understood that the case for the complainants cannot be ended this week; and, when it is concluded, the Managers will perforce have to adduce a still greater mass of rebutting evidence, including, first, the evidence of the Managers themselves, who are among the most highly respected names in London, and include gentlemen holding the highest positions in connection with the great voluntary metropolitan hospitals, and some distinguished medical men; then that of the sisters and nurses; the medical Inspector of the Poor-law Board; some well known hospital physicians and surgeons who have at different times inspected the wards; and a selection from a host of patients contemporaneous with those who have testified, and who offer denials of the alleged abuses. The charges made are of a very shocking character; they have, however, by no means well stood the test of cross-examination; and we believe that the general impression in medical circles is, that the case is tinged with palpable exaggerations, and that the more serious charges are clearly breaking down. Had the pledge given by Mr. Hardy in the House of Commons, that visiting physicians should be appointed to these asylums, been carried, it seems probable that circumstances could never have occurred which have given a colour to this scandal.

#### TERCENTENARY OF HARVEY.

PRELIMINARY steps have been taken at Folkestone—the birthplace of the illustrious author of the circulation of the blood—to mark the tercentenary of Harvey's birth by the erection of a suitable public monument to one of the greatest of Englishmen and most illustrious of the world's true heroes. It is not to the credit of our country that no such public monument exists. At a meeting convened by influential requisition, the Mayor of Folkestone in the chair, letters were read from Earl Granville, Baron Rothschild, M.P. for the borough, Lord Robert Montagu, M.P., Dr. Bence Jones, F.R.S., and other influential persons, and the Presidents of the Royal Colleges of Physicians and Surgeons, warmly approving, and proffering support. Mr. George Eastes, M.B., with whom the movement originates, read an interesting sketch of the life, labours, person, and character of Harvey. Mr. John Simon, F.R.S., the Medical Officer of the Privy Council, supported the project in an eloquent speech. Dr. Bateman, Dr. Bowles, and other local gentlemen, moved resolutions appointing a numerous committee, nominating Dr. Bence Jones, F.R.S., Treasurer, the Town Clerk of Folkestone and Mr. George Eastes, M.B. London, as Honorary Secretaries; subscriptions to be received at the Branch Bank of England to the credit of the Fund. When we wish to think well of ourselves, and to establish a claim on the gratitude of mankind, we call ourselves the countrymen of Harvey and of Jenner, whose discoveries have done more for the relief of mankind and the saving of life, the glory of science and the progress of biology, than those of any other two men, past or present. Let us show that we know how to honour their memory.

#### A FRENCH MEDICAL WAR MEDAL.

THE French Minister of War lately laid before the National Assembly a *projet de loi* authorising the government to strike a medal to be awarded to those who gave their disinterested services to the ambulances during the late war. The honour is to be conferred not only on males, but on females, who, says the minister, "took so large a share in the acts of benevolence and humanity performed during the painful crisis through which we have just passed."

#### LUNATIC ASYLUMS.

FROM a return moved for in the House of Commons by Lord Robert Montagu, and lately issued, we learn that in the various borough and county lunatic asylums in England and Wales on the 1st day of July last there were 31,474 inmates, of whom 19,905 were members of the Church of England, 2,835 Roman Catholics, 7,099 belonging to other denominations, and 1,635 whose denomination was unknown.

## DR. BLACKMAN OF OHIO.

THE late Professor G. C. Blackman of Ohio, whose death, at the age of 52, is announced, was well known in this country as a bold and accomplished surgeon, enthusiastic in his profession, and accomplished in its highest branches as a science and an art. He was personally known to more than one of us in this metropolis. In 1855 he became an occasional student at the London hospitals, subsisting in London, by a system of the most rigid self-denial, for some months on about fifteen pounds—"studying covered with bed-clothes to avoid the expense of a fire, and subsisting on two penny rolls a day." He was treated with characteristic kindness, which he never forgot, by a surgeon whose kindness and nobility of character have endeared to him many hundreds of pupils and friends. Mr. George Pollock of St. George's Hospital and Sir William Fergusson also received him kindly and hospitably. At a later date he was one of the very few foreign surgeons elected member of the Royal Medical and Chirurgical Society. Although he attained to great eminence and wide repute, he seems from various circumstances to have failed to realise a fortune.

## DEATH AT THE LONDON HOSPITAL FROM CHLOROFORM.

ON Saturday, Mr. Richards, the deputy coroner for East Middlesex, held an inquiry at the London Hospital into the circumstances connected with the death of a lad named Edmond Kitching, aged 15 years. It appeared, from the testimony of the relations of the deceased, that about a month ago he was taken before the bench at the Guildhall, to be dealt with on a charge of having no visible means of sustenance, in consequence of being found by an officer sleeping, at five o'clock in the morning, in the open air. He was sent to the boys' home in Regent's Park Road; but on the 4th instant was removed to the hospital for treatment for an internal disease. While there, he requested that an operation might be performed on one of his eyes, in order that a squinting under which he laboured might be removed. The necessary preparations were made for the performance of the operation; and on the 24th instant he was placed under the influence of chloroform, which was administered by Mr. Tay. After the completion of the operation, the deceased, upon recovering from the effects of the drug, made efforts to vomit. While doing so, he gave a deep inspiration, which had the effect of forcing back the rising matter, and causing his death by suffocation. The jury returned a verdict of "Accidental Death."

## THE NEW HOG-PARASITE.

It will be seen from a communication in another column from Dr. T. Spencer Cobbold, F.R.S., that the new hog-parasite which he described and identified in our columns in January last as the *Stephanurus Dentatus*, from specimens sent from Indianapolis, appears again amongst some slides of entozoa forwarded from New South Wales. This affords an interesting confirmation of the anticipations then expressed, and adds an item of value to the progress of helminthological science in its agricultural relations.

## SMALL-POX AT BRIDGWATER.

AN inquiry has been ordered to be made by the Local Government Board, relative to the small-pox epidemic in this town. Until within a few days, the *Bridgwater Mercury* says, when cold weather began to set in, the disease continued to spread, not only in Bridgwater, but in several of the neighbouring parishes; and during the past fortnight several cases have terminated fatally. This is exactly what we anticipated. But the fatal result might have been obviated, had the advice given in these columns to the Bridgwater guardians, at the commencement of the outbreak, been promptly taken. Had a temporary hospital been erected, or even an encampment pitched on the immense artificial mound by the canal basin, recently and generously placed at the disposal of the town by the Bristol and Exeter Railway Company, the progress of the disease might have been checked at once. To save money, the guardians huddled the small-pox cases

under the same hospital-roof with the general patients, who were constantly shifting either homeward or houseward. *Hinc illa lachrymæ.* Other tears, however, are to be shed. The guardians have decided upon attending to the request of the Local Government Board, and on furnishing a report, through the district medical officer, on the origin and prevalence of the disease, and on the steps which have been taken in reference to it under the fourteenth section of the Nuisance Removal Act, 1870. One of the guardians, whose ill advice has done much to promote the spread of the disease from the first, of course thought that the guardians were entitled to ask their medical officers to furnish such reports *gratuitously*. This preposterous idea was not, however, shared by the majority; and the result is, that each district medical officer is ordered to furnish the Board with a report for his district, in consideration of which the guardians will reward his labours with a guinea! Surely the small-pox is making some remarkable revelations illustrative of the penny-wise and pound-foolish policy. Would it were only £ s. d. that have been sacrificed.

## THE NOMENCLATURE OF THE PHARMACOPŒIA.

MR. C. R. C. TICHBORNE, a very competent pharmaceutical and chemical authority, discusses with approval the changes in nomenclature and notation of the *Pharmacopœia* proposed by Mr. Atfield, to which we lately referred. He is convinced that, when a new edition of the *Pharmacopœia* shall be issued, which will not be just yet, we shall have the new atomic weights and a binary notation and nomenclature in conformity with the new system alone. He thinks that the great difficulty in the perfect acceptance of the new nomenclature and notation in pharmacy is, that most of the medical licensing bodies do not make it compulsory that the candidates should answer in the new notation. As long as it is optional with the medical student, it will never be perfectly adopted, for pharmacy must sail in company with the practice of medicine. Now we find that in the year 1870 there were in this kingdom 1160 medical students registered, being much in excess of the pharmacists. With the pharmaceutical student the acceptance of the new system is easy; chemistry is his principal and most difficult study. With botany, it constitutes all his science; he must have both a theoretical and practical knowledge of it, or he is no pharmacist. He therefore will not mind a little more trouble, for the new system is a degree and only a degree more difficult. But chemistry hitherto has formed but a small part of the medical student's education, and the little he has learned he has looked upon as a matter of secondary importance. In such a case, if the student be presented with two roads, he will very naturally take the short one. We commend the papers of Messrs. Atfield and Tichborne to the notice of the *Pharmacopœia* Committee of the General Medical Council, on the part of which we shall not be sorry to see a little more obvious activity.

## DEATH-CERTIFICATES.

WE have received a copy of a Manchester paper containing a report of an inquest at Eccles on the body of a man who died suddenly. Dr. Haddon had been attending him, and was summoned at the moment of his death. Dr. Haddon, we believe, was of opinion that the case was one of pyo-nephrosis. An inquest was held, at which it transpired that Mr. Roe, who had not seen him for six months, had given a certificate that death had occurred from heart-disease. We must remark that the responsibility of giving death-certificates without accurate knowledge of the immediately preceding conditions, and absolute conviction arising from that knowledge and from inspection of the body, is a dangerous and improper proceeding. The practice of giving death-certificates, under any circumstances, without seeing the body, is open to abuse. Dr. Burke, Deputy-Registrar of Ireland, related to the Sanitary Commission, in his evidence on this subject, a case in which a well known physician, who had accepted the statements of relatives as to the decease of a patient whom he had been quite recently attending, found that patient next day sitting up in his drawing-room. Sir Dominic Corrigan

has also related instances *ad rem*, in his able paper on the subject of Registration. In the present case there seems to have been a really deplorable and extreme laxity of practice on the part of the giver of the certificate. Dr. Haddon was obviously best able to form an opinion as to the cause of death. To grant a certificate alleging the cause of death for a patient who died suddenly, and who had not been attended for six months by the author of the certificate, is a proceeding so unquestionably wrong, that it is difficult to find an excuse for it. The adverse observations of the coroner were fully justified. It is not necessary to warn medical practitioners against such a course; but it may be well to remind them that their certificates may easily be made the means of dangerous abuses and frauds by designing persons, and to repeat the counsel of extreme caution in granting them.

#### THE MEDICAL TEMPERANCE QUESTION.

A PICTORIAL Drink-Bill of the British Nation, prepared by the Rev. Dawson Burns, recalls, by means of a strikingly clear and effective pictorial chart, the distressing fact that the annual expenditure on alcoholic drinks of the nation amounts directly to the enormous sum of £108,000,000, half as much again as the whole annual government expenditure, more than twice as much as the annual produce of British mines or the annual railway receipts, and £20,000,000 more than the annual exports of British textile manufactures. The total annual loss of the British nation from the expenditure on intoxicating liquors is set down at £216,000,000. These are very startling and distressing figures, and we see no reason to challenge their correctness. The *Medical Temperance Journal*, in its October quarterly number (Tweedie, 337, Strand), contains a very interesting article by Dr. A. H. H. McMurtry of Belfast, on the Duty of Medical Men in Relation to the Temperance Movement. Dr. McMurtry writes very earnestly, very strongly, and with all the fervour of overwhelming conviction of the importance of his subject. And, indeed, looking to the ineffable misery and disaster, the waste, degradation, suffering, and crime, which are constantly wrought in this and most other civilised nations by drink, we are far from thinking that the importance of the subject can be exaggerated. The influence of medical men, if they were united and agreed, might be all powerful on this subject; and we should be glad to see a conference of medical men, including those of the highest class, originated in some really influential quarters, with a view to giving this subject a more thorough discussion than it has yet had. We should like to hear a discussion in which Parkes, Edward Smith, Hughes Bennett, A. P. Stewart, Paget, Jenner, and some of our leading provincial practitioners, would take part, in which the whole subject should be probed. To what extent, if it all, are physicians justified in recognising alcohol as an article of daily food in health? Does the habit of prescribing alcoholic drinks act injuriously upon the morals and welfare of the people? Is it possible or desirable to substitute the more enticing forms of alcohol by medicinal and less alluring forms? We all of us sympathise with the ends which the National Temperance League has in view. A small minority only practically participate in their means of action. Can we in any way, and in what way, help to rescue this nation from the curses which drink brings upon its population?

#### THE RED CROSS IN ENGLAND.

THE *Worcestershire Chronicle* calls attention very truthfully to the leading part taken by Captain Burgess and Captain Furley, as founders of the movement which led to the formation of the English order of St. John (rather a silly device), and the vigorous Aid Society, its offspring, which has superseded the parent. The exertions of Captain Burgess have hardly been sufficiently known to the public, but they are none the less appreciated by the wide order of actual workers in the cause. Burgess and Furley were unquestionably the primary founders, and worked incessantly as soldiers in the army which they originated. Without Colonel Loyd Lindsay, however, it is probable that they would have had but little success in their first operations.

#### IMPROVEMENT OF THE CAM.

THE Cambridge Board of Town and University Improvement Commissioners are on the eve of a discussion materially affecting alike the interest of the ratepayers and the health and comfort of the inhabitants of the borough and the members of the University. It is sought to amend the sanitary condition of the town by diverting its sewage from the River Cam.

#### RE-VACCINATION AT OXFORD.

SMALL-POX is still epidemic, though in a condition of subsidence, at Oxford. There were thirty deaths from it in the past four months. The Vice-Chancellor has very wisely recommended to undergraduates who will come up next term, that every young man who has not been properly revaccinated within the past seven years, or since he attained the age of 17, should submit to the operation before his return on Oct. 13. We heartily hope that the revaccination will be performed *very carefully*, and that proper certificates of the same will be required.

#### HOMŒOPATHIC CONGRESS.

THE following report is published in the daily papers.

"Yesterday about fifty homœopathic medical practitioners assembled at the Randolph Hotel, Oxford, for the purpose of hearing papers read and discussed, etc. Dr. Hughes (Brighton) read a paper on 'Therapeutics in its relation to Modern Physiology', prepared by the President for the year, Dr. Madden (London), who himself was unable to be present, having, unfortunately, recently sustained an attack of apoplexy. Dr. Black (Clifton) read a paper on 'Posology', which led to an animated discussion as to the efficacy of high and low doses—the result of the testimony borne by different practitioners being somewhat indefinite, varying with varying circumstances. Homœopaths would seem to be inclining to meet allopathists half way, the latter on their part having of late years considerably modified the wholesale dosing which was in vogue in bygone days. Other papers were read and discussed. The proceedings concluded with a dinner. The Congress decided that the next meeting should be held at York the first Wednesday in September, 1872. Dr. Black (Clifton) was elected President for the year ensuing; Dr. Dunn (Doncaster), Vice-President; Dr. Pope (London), General Secretary; and Mr. Nankwill, Local Secretary."

This is a method of rattling which is by far more ingenious than ingenious. If the gentlemen who called themselves homœopathic have become convinced of the fallacy of their "infinitesimal" dilutions and dynamised powers, it would be but honest to say so. They only make the sham, which they dignify by a Greek title, more dishonest when they pretend that they are on the way to "a compromise", and that practitioners of rational medicine have on their side modified their doses to meet them. Of course the progress of diagnosis and of science, and variations of type of disease, have changed some of our modes of practice. But a comparison of pharmacopœias of this date and fifty years back will particularly show no change in doses. They have remained more stable than anything else in our progressive art; and our doctrines and practice are, if anything, more directly opposed to the follies of the homœopathic principle now than at any time. The fallacious semblances on which they relied have been nearly all shattered, and the doctrine of elimination was the tombstone of homœopathy. Over the places where they wrote "*Similia similibus*", it writes everywhere "*Tolle causam*."

#### SCOTLAND.

##### UNIVERSITY OF EDINBURGH: ETTLES SCHOLARSHIP.

AT the recent graduation, the Ettles Scholarship, which is annually awarded to the most distinguished graduate, was given to Dr. Urban Pritchard, a student of King's College, London. Dr. Pritchard also gained a gold medal for original researches on the structure of the organ of Corti, conducted by him in the physiological laboratory of King's College.

## RELAPSING FEVER IN GLASGOW.

WE observe that while, during the last fortnight, the health of the city has been quite exceptionally good (the death-rate not quite reaching 25), there is a prospect of an increase in relapsing fever during the winter. Dr. Gairdner, in a report to the Police Board, says: "Looking to the type of disease reported in detail, and to the records of the last three or four months, there seems no reason to doubt that relapsing fever, partially subdued during the heat of summer and in consequence of the open-air life adopted in June, July, and August, by many of the dwellers in our low tenement houses, is again tending to develop itself, in proportion as the nights become colder and overcrowding becomes more favourable to the spread of infection."

## GLASGOW MEDICAL SCHOOLS: THE WINTER SESSION.

THE classes in the Glasgow medical schools will be resumed on October 31st. The students of the University will still be subject to the same inconvenience as last session, of having the University and the Infirmary separated by a distance of over two miles. We believe that last winter this inconvenience was submitted to with perfect good nature on all hands, and we feel sure that the same will be the case this winter. The University authorities are pushing forward the new hospital as quickly as possible; and we understand that an effort will be made to open an out-door dispensary there at the beginning of the coming session.

## THE CITY IMPROVEMENT SCHEME IN GLASGOW.

GLASGOW possesses the unenviable distinction of being the most closely built and densely peopled city in the kingdom; and, we do not doubt in connexion with this, it is one of the most unhealthy. Any one who has ever traversed the central parts of the city must have been appalled at the closeness with which lofty and densely populated blocks of houses were set down, leaving merely narrow lanes, much resembling ditches, between the high walls of the opposite tenements. It was in view of this striking state of matters, and of the high death-rate, which it was impossible not in some degree to associate with it, that, six years ago, the City Improvement Scheme was set going. Compulsory powers of purchase were obtained from Parliament; and the process of buying up properties, the demolition of them, and the opening up of new streets, was at once set about. At first, there seemed to be very little done. At each annual meeting for a number of years, there was the report of large sums of money being expended, and yet no apparent difference was made in the face of the city; and the death-rate kept as high, and even mounted higher than formerly. There was then, of course, the usual outcry against the useless expenditure, and the scheme ran some risk of coming to a premature end. The good sense of the citizens, however, prevailed, and the scheme was proceeded with; and it is with eminent satisfaction, as we think, that the fifth annual report must be viewed by all interested in the sanitary condition of large cities. One who has not visited the parts of Glasgow concerned for a number of years would find it difficult to realise the amount of change which has now been effected in the denser parts of the city. New streets have been formed; densely populated lanes have been converted into wide thoroughfares; and altogether the place has much less of the appearance of squalor than it formerly possessed. During these five years, 1,150 dwelling-houses have been demolished, and a population of about six thousand displaced from the densest part of the city; and the consequence has not, as might have been expected, been an increase in the overcrowding in the central districts, but the people displaced seem ready to have taken the hint and moved their camp towards the suburbs; this being evidenced by the fact that the prosecutions for overcrowding have even diminished in the midst of all this demolition. The efforts of the City Improvement Scheme have been in some degree seconded by the formation of the Union Railway, which was simultaneously buying up and demolishing property in the densest parts of the city. On the whole, there has been a most mani-

fest improvement in the appearance of these parts of the city; and we do not doubt that the praiseworthy efforts of the citizens will be ultimately rewarded by a reduction in the death-rate.

## IRELAND.

## SANITARY AFFAIRS IN DUBLIN.

DR. GRIMSHAW, Physician to the Cork Street Fever Hospital and Steevens' Hospital, writes to us:

"As Dr. Mapother has undertaken the defence of the Dublin sanitary authorities against the charges brought by Mr. Baker and myself, perhaps you will be good enough to allow me to point out what charges have been made, and how far they have been answered. Dr. Mapother has made so many countercharges, and thus so far complicated what was at first a simple enough question, that your readers who do not see the Dublin daily journals may have some difficulty in understanding how the matter stands at present; I therefore offer a few explanations.

"The charges against the sanitary authorities may be thus summarised. 1. The scavenging of the city is so bad that it is (especially in the poorer streets) dangerous to the health of the public. 2. The disinfecting chamber is out of order, and unfit for use; and, if in order, no means have been taken to bring articles thither for disinfection. 3. Houses reported as fever-nests have not been attended to by the authorities; and complaints sent to the City Hall concerning nuisances, etc., are usually not attended to. 4. The authorities have not provided proper privy and ash-pit accommodation for the poor, nor taken measures for the cleaning of such wretched accommodation of this sort as at present exists.

"On the defence side we have: 1. No defence of the scavenging neglect, but a statement that this does not concern the Health Committee, but Committee No. 1 of the Corporation. 2. A denial that the disinfecting chamber is out of order, although proved to be unfit for use by Mr. Baker before, and by the reporter of *Saunders' News-Letter* and me after this denial had been made. 3. No defence has, up to the present, been attempted against the charge of neglecting the reports of fever-nests and other nuisances. 4. No defence has been made of the state of the privies and ash-pits; but this charge has been admitted by the Health Committee, by its issuing (for the first time) a notice 'to all whom it may concern' to cleanse the same at particular times, thus casting the duties of the sanitary authorities on *any one* whom it may concern.

"The rest of Dr. Mapother's defence of his masters consists in bringing charges against other people, bodies or places, as follows: Against Mr. Baker's dispensary district, for being in a worse sanitary condition than Dublin; against other towns generally for being worse than Dublin; against the authorities of Cork Street Hospital, for not providing sufficiently detailed returns to the City Hall, although returns containing all available information are sent to the City Hall twice a week, and are habitually neglected by the Sanitary Committee, as is shown in a letter appearing in the Dublin papers this morning; against the fever-hospitals for not using their cabs as foul clothes-carts for the Corporation disinfecting chamber, although one of these hospitals has no cab, and the other has a disinfecting chamber of its own, built within the hospital in the year 1803; against the commissioner of the *Freeman's Journal*, for making a mistake about the Coombe Hospital, in a very graphic report upon 'The Four Kings' Prisons', although he did not charge any of the defects (if there be any) of the Coombe Hospital to the sanitary authorities; and, lastly, against some one for making a mistake about a cholera ship in the river.

"The most amusing episode of the whole discussion is the threat of the Health Committee to put the law in force against the Scavenging Committee, to remove a nuisance created by the latter committee on the banks of the Royal Canal, and complained of by the Rev. Mr. Duran, P.P., in a letter to the *Freeman's Journal*, as dangerous to the health and lives of the inmates of a large orphan asylum in the immediate vicinity."

## NOTES ON THE ANNUAL MUSEUM.

THE following are a few notes on some of the leading contributions to the Annual Museum at the Plymouth meeting.

**CLASS I. Medical and Surgical Instruments and Appliances.**—Dr. Woodward's obstetric support (No. 7 in the catalogue), exhibited by Mr. Plum of Worcester, is designed for expediting labour and preventing *post partum* hæmorrhage.—Messrs. Arnold and Sons of London, were large exhibitors of some of the latest inventions. Amongst them was Dr. Angove's accident case (17), which would be improved by placing cork partitions between the instruments, or by embedding the instruments in a block of cork. This would add very little to the weight of the case, whilst it would prevent the edges of the knives from being injured.—Mr. W. Miller's instrument, for the cure of bunion (36), attracted attention.—Mr. Jessop of Leeds exhibited an instrument (39) for facilitating the *post mortem* examination of the head, and a somewhat similar contrivance for keeping a patient's head steady during operations on the eye, etc. These useful inventions are described and figured in the JOURNAL of September 2nd.—Messrs. Mayer and Meltzer of London exhibited a very choice selection of instruments. For high-class workmanship they could not be surpassed.—Mr. C. Steele of Clifton exhibited his flexible probes (61), which he has lately compared with Sayre's probes, showing a similarity of design.—Mr. Greenway exhibited several of his inventions. His grasping-splint (62), for severe fractures of the leg, keeps the fragments in position without interfering with the circulation. Fomentations and dressings can be applied to the naked limb without causing any disturbance at the seat of injury. His unilateral limb-suspender (63), described by Mr. Haynes Walton, at a meeting of the Medical Society of London, as "one of the best appliances of modern surgery", attracted the notice of the visitors. This apparatus can be used for the upper or lower extremity, not only in the treatment of fracture, but of inflamed joints or any ailment requiring absolute rest in the limb during the various movements of the patient. Mr. Greenway's unilateral bed-guard (64), although a simple contrivance, has proved of the utmost service in the removal of the weight of bed-clothes from various parts of the body. This, as well as the suspender, being one-sided, the patient is scarcely aware of their presence in the bed. His irrigating apparatus (66), first employed at St. Mary's Hospital, and described in the JOURNAL of September 24th, 1870, was exhibited and placed in position on a bed. Its employment has been attended with the best results.—The ophthalmic suction instruments (67, 68), by the same inventor, were also exhibited. To Mr. Greenway belongs the credit of having made the application of suction, to parts within the eyeball, safe and practicable.—Mr. Ernst of London sent a very valuable collection of orthopædic apparatus (82-98). They were exquisitely finished, and nothing better of the kind could be desired or even obtained.—Messrs. Krohne and Sesemann, of London, also sent a good assortment of instruments (99-120). Some of them were plated with pure nickel, thereby preventing rust, and affording other advantages.—Mr. W. Heath, a Plymouth optician, exhibited a choice collection of microscopes, etc. (121-130). Two were of full size (one of them binocular), with completely revolving glass stages, affording the utmost facility for manipulation and perfect cleanliness in use. These, as well as his student's microscope, were well put out of hand and moderate in price.—Messrs. Maw, Son, and Thompson, sent a contribution (131-139). Their urinary test-stand was very complete and well furnished. Dr. Barnes's excellent apparatus for dilating the os uteri and for injecting perchloride of iron solution is too well known to require comment. Dr. Potter's speculum must be intended for a very capacious vagina. We presume that smaller sizes are made. The latest form of dilating reflectors bids fair to take the place of all glass specula. Mr. Greenway's improved ophthalmoscope is a boon to the student, enabling him to view the fundus of the eye without any difficulty, the position of the mirror and lens being arranged before the observer commences the examination. Dr. Mackenzie's inhaler is an admirable contrivance for administering medicated vapours. Being made of glazed earthenware, it is not liable to become foul or to corrode. Mr. Blackbee's pessary and speculum were also exhibited by this firm. The speculum is more of a dilator than an illuminator, being composed of plated wire so bent on itself as to form a kind of skeleton tube, capable of being compressed or expanded by means of a traversing ring. The Messrs. Maw's sample of spongetents was very good.—Messrs. Wood, manufacturers, of Manchester, exhibited among other instruments Bradley's insufflator (a puff-ball and tube) for dusting the fauces and air-passages with nitrate of silver, alum, etc.; also their vaccination-guards to protect the vesicle. These

inventions only require to be seen to be appreciated.—Dr. Hearder (D. Sc., etc.), a medical and general electrician, of Plymouth, exhibited a few of his medical electro-magnetic coil machines (155). They are very compact, have great extent of power and facility of manipulation, and are graduated accurately and uniformly. The unit of force forming the basis of these graduations being the same in all these instruments, electricians are not only furnished with a common standard for the comparison of the results of their experiments, but with a ready means of electrical diagnosis. Another point in their favour is the moderate price at which they are sold by the inventor.

The special exhibition of fracture-apparatus, suggested and carried out for the first time this year by Mr. Greenway, was interesting, and served to draw forth various comments as to the best mode of treating fractures. The inventions shown in this branch were: Appliances for the upper extremity (40), by Mr. McVail of Alnwick Infirmary; Surgeon-Major Wyatt's battle-field splint (54), by Mayer and Meltzer, an admirable contrivance, not only in cases of emergency, but in routine practice; Mr. Greenway's appliances (62, 63), already alluded to, and his suspender for two broken legs (65). The following (70-81) were shown by Messrs. Weiss: Lonsdale's splint for fractured patella; Weiss's arm and humerus-splint; a set of six-jointed elbow-splints; Weiss's jointed radius-splints; Liston's leg-splint; Fergusson's excision-splint; Busk's thigh-splint; Fergusson's leg-splint; Salter's sling; Weiss's fracture-cradle, with side-splints; and Lawrence's back-splint.—By Mr. Ernst: Wire-splints (98) for fluid dressings—most useful appliances, enabling the surgeon, if necessary, to apply irrigation during the treatment of fracture.—By Mr. G. Cordwint of Taunton, his ingenious apparatus (142) for compound fracture of the lower extremity, allowing dressings to be applied with ease.—By Mr. Jonathan Hutchinson, a side-leg splint with back-piece (145), for the treatment of fractures above the ankle, with displacement of the foot backwards; a splint for the treatment of fractures of the humerus (146); and numerous illustrations of the application of hatter's felt to the construction of splints (147).—By Messrs. Cow, Hill, and Co., of Cheapside, air-splints (153), or inflated India-rubber junks, which serve the purposes of splint, pad, and bandage. These almost unknown appliances, which were invented nearly thirty years ago by the late Mr. Cow of Devonport, deserve the attention of surgeons.—Mr. Greenway was the only exhibitor of drawings of ancient fracture apparatus, he having employed artists specially for the occasion.—Mr. Christopher Heath exhibited two illustrated works on fractures—Hamilton's and Malgaigne's. We hope that Mr. Greenway's idea of a special display in connection with the museum will prove fruitful, and that each year will have its special features.

**CLASS II. New Drugs and Preparations.**—Messrs. Southall, Son, and Dymond, the well-known manufacturing chemists of Birmingham, exhibited a case of specimens of opium and cinchona barks, and the analysis of each. This was very instructive, showing the great inequality in the medicinal value of different specimens of the same drugs, and therefore to what an extent the prescriber is in the hands of the druggist. The difference in the percentage of morphia in the various specimens of crude opium was very great. They also exhibited preparations of opium and of cinchona barks made with drugs of uniform value, and various specimens of, and preparations made from, "quinovia" or cinchona bark without the woody fibre. Their surgical dressing "tenax," a superior kind of oakum, was displayed in bulk. It is being extensively adopted, and in a coarser form has long been held in repute among sailors as a covering for wounds, the tar which it contains forming an important element in its usefulness. We shall have a further word or two to say about these preparations another time.—Messrs. Howards and Sons, the celebrated alkaloid manufacturers, exhibited samples of sulphates of quinine, quindine, cinchonine, and cinchonidine. The name of this firm is a sufficient guarantee for the quality of these productions.—Amongst the drugs exhibited by Balkwill and Son, of Plymouth, was a liquid extract of poppy, proposed to replace the syrup of poppy. As the latter often undergoes fermentation, we consider the proposal a right one.—Mr. S. B. Turney, a Plymouth chemist, exhibited a choice selection of drugs.—Messrs. Calvert and Co., of Manchester, exhibited samples and preparations of carbolic acid. Their soaps are of great value, not only in the treatment of skin-affections, but for ordinary use, especially by members of the medical profession who are frequently exposed to contagion. Their carbolised tow for dressing wounds deserves the attention of surgeons.—Mr. Agnew, of Liverpool, exhibited samples of his "cod-liver oil jelly," with and without pepsine and pancreatine. These preparations will be very acceptable to a large class of patients, but we think they would be improved by simply using lemon as the flavouring ingredient.—The preparations of "koumiss" exhibited by the manufacturer, Mr. E. Chapman, attracted much notice. The virtues claimed for this drink in other countries necessitate its trial by the profession in this country.

**CLASS III. Articles of Diet.**—Messrs. Peak, Frean, and Co., biscuit manufacturers, of London, exhibited samples of various kinds of biscuits suitable for invalids. The purity, composition, and appearance of these articles of diet cannot fail to ensure a large consumption.—Messrs. Dunn, Hewett, and Co., cocoa manufacturers, of London, exhibited various samples of their manufacture. They all possessed good flavour, and were perfectly free from adulteration.—Messrs. Fry and Sons, of London and Bristol, also exhibited various preparations of cocoa. They were pronounced full-flavoured, especially the Caraccas variety, and of great purity. Their quinoa chocolate-drop, each containing one-third of a grain of Southall's quinoa, is an admirable method of administering cinchona to children. This preparation deserves to rank with the lozenges of the *Pharmacopœia*.—Van Houten's "pure soluble cocoa," exhibited by Mr. H. Eschwege, of London, is true to its maker's description. This was the only specimen exhibited by this manufacturer, and a purer or more delicately flavoured article of its kind it would be impossible to procure. For patients suffering from indigestion cocoa is far preferable to tea or coffee, which frequently aggravate the malady.—Messrs. Orlando Jones and Co., of London, exhibited samples of their "entire wheat-flour." As an article of diet, it ought to be universally adopted, not only by invalids, but by the public generally.—Messrs. Summers and Co., of Bristol, exhibited samples of their aerated waters. They were all high-class productions, and remarkable for purity.—Mr. Max Greger, of London, exhibited some of his Hungarian wines. They were all highly approved of, and the "Ruster" was generally considered well-suited for cases of nervous exhaustion arising from fatigue or other cause.—Mr. Verkrüzen, of London, placed before the Association samples of German, French, and other wines. It has seldom fallen to our lot to taste such high-class productions, several of them at a price suitable for hospital consumption. Mr. Cory, the agent in attendance, deserves great praise for the manner in which he introduced the wines to the notice of the members.—The "Essa Brewery Company," Saltash, Cornwall, submitted their pale ale and nourishing stout to the notice of the meeting. Both these articles were very grateful to the palate, and, as specimens of pure malt liquor, reflected great credit on the brewers.

**CLASS IV. Pathological Specimens, Casts, &c.**—This class contained a number of interesting specimens and drawings. Mr. Jonathan Hutchinson, who was the principal contributor, sent a large collection of photographs, coloured sketches, portraits illustrating the occurrence of syphilis and other diseases after vaccination, and pathological specimens. Specimens were also exhibited by Mr. Christopher Heath, Mr. Jessop, Dr. G. Johnson, Mr. J. H. Fuge, Mr. P. W. Swain, Mr. Charles Steele, &c. We shall probably return to this interesting department of the Association on another occasion.

**CLASS V. Medical Literature.**—Numerous works on medicine and the allied sciences were exhibited by Messrs. J. and A. Churchill, Mr. H. K. Lewis, Messrs. Baillière, Tindal, and Cox, the New Sydenham Society, &c.

**CLASS VI. Miscellaneous.**—There were very few objects exhibited under this head. The most prominent were the drawings of Mr. Greenway's proposed plan of hospital construction, by Mr. James Hine, of Plymouth, an architect of good standing in the western counties. As Mr. Greenway read a paper on this subject, and it will shortly appear in the pages of the JOURNAL, we shall reserve our comments for another occasion.—Dr. A. Mackintosh, of Callington, sent his prize Herbarium. For want of space it could not be properly displayed.—A very interesting collection of crystals and fossils was exhibited by Mr. Robert Oxland, of Plymouth.

## POISONING BY ARSENIC IN WALL-PAPERS OF ALL COLOURS.

### II.

The following is from the pen of the correspondent whom we have already introduced to our readers in connexion with this subject.

Having in a previous paper endeavoured to draw special attention to the very serious dangers resulting from the use of arsenic green colouring in wall papers, even where only a spot or line of green occurs in the patterns, it is of no less importance to make known the fact that arsenic is used not only in papers containing green, but frequently and even in large quantities in papers of all colours, even occasionally in some that are nearly white. I state this on the authority of an eminent analytical chemist, late lecturer on chemistry at St. Bartholomew's Hospital, to whom I sent some months since the papers of several rooms, which, although totally free from green colouring, I suspected to contain arsenic,

because of various symptoms in the occupants of the rooms which appeared to me to indicate chronic poisoning by arsenic. The results of analysis proved that in every instance the persons alluded to (including two physicians) were occupying arsenic-papered rooms, not one of which contained even a speck of green. These papers were of many colours—dark-brown, buff, white, blue, and various delicate shades of grey, drab, and mauve. Two were chiefly white; and of these two, very similar in appearance, one contained a very little arsenic, and the other a large quantity, thus proving that it is quite impossible for any one, professional or otherwise, to judge by the eye whether a paper contains arsenic or not, or whether much or little. The indications of arsenical poisoning caused by the papers containing only a little arsenic were clear in each case.

In my former communication, I stated that in my own household great relief followed the removal of the papers containing green. Such was the case. The very dangerous symptoms ceased shortly afterwards, and we hoped recovery would follow, but there continued an under current of chronic irritation which could not be accounted for, and baffled medical skill. The situation of the house was remarkably healthy, the drainage good, and every room well ventilated. But the improvement we had experienced at first did not continue, and, about nine months after the removal of the green papers, the former alarming symptoms threatened to reappear in every case, and aroused my suspicions that we were again suffering from arsenic. I then had the papers analysed, and the result was that arsenic was found in the papers of every bedroom in the house and of one sitting-room. Thus we, who had previously suffered enough to have a wholesome dread of this terrible poison, found that we had unwittingly replaced the papers containing green with other arsenical papers; and, although these latter contained only small quantities of arsenic, the results became very serious after occupying the rooms for a few months. On removing these papers, and colouring the walls with a wash of whiting and size, tinted with safe colours (such as ochre and Indian red), immediate relief followed, and health has been steadily improving since; but spending an hour or two in an arsenic-papered room, or wearing articles of dress containing the slightest trace of arsenic, speedily brings back the former symptoms more or less severely. It is now six months since we removed these papers, and the improvement since then has been decidedly satisfactory; but after many years of severe poisoning, recovery can only be a gradual process, and it is to be feared that some ill effects must last for years, if not for life, especially in the case of those who no longer have youth on their side to assist the reparative process.

One point worth noticing is that, since we have had no papers on our walls, the atmosphere of the rooms has been far purer than before. It appears to be generally the case that where wall-papers contain any arsenic, the atmosphere is more or less close and heavy, and no amount of ventilation or cleansing will prevent this. Directly the windows are shut, the want of oxygen is perceptible, and some persons therefore find it necessary both to sit and sleep with either door or window open, feeling a want of pure air, while ignorant of the cause. But I have also known cases where arsenic-papers so injured the sense of smell, that this closeness was not perceived until the breathing became affected, and then the need of fresh air was seriously felt. It may be well to mention that, in substituting distemper or oil-paint for paper, it is necessary to be very careful as to the composition of the colours, as many of the pigments used both for oil-paints and for distemper appear to contain arsenic, and have proved injurious; in consequence of which the use of arsenic in oil-paint, as well as distemper, has been prohibited in Prussia for the interior decoration of houses. But that subject needs to be gone into by itself. I have lately had some papers analysed, containing chiefly blue-colouring, which proved to be arsenical; and it appears to be very generally the case that persons occupying rooms where there is blue in the paper, suffer from the same class of symptoms as are produced by papers containing green. It was, in fact, my own experience in blue-papered rooms, and observations made in other cases, combined with the fact that cobalt blue is derived from an arsenical ore, which first led me to suspect the presence of arsenic in other papers besides green. "Arsenical cobalt" is the name given to the ore from which both the cobalt and arsenic of commerce are obtained, and is so-called because cobalt is almost invariably found in combination with arsenic. The processes by which the arsenic is separated from the cobalt appear to purify the latter but imperfectly, for I am informed that the dealers in cobalt consider it pure when it retains ten per cent. of arsenic! Consequently the cobalt blue used in wall-papers, distemper-colouring, and oil-paint is probably never free from arsenic, and therefore papers having blue in the pattern should be avoided. Mauve papers likewise appear to be very frequently arsenical. I also know of cases where arsenic was found in red papers, and produced the usual ill effects, no remedies being of any permanent use until the papers were removed,

when the illness ceased. The circumstances were related to me by the physician who attended in one instance.

It is very generally believed that a small quantity of arsenic in a paper is not injurious. Even where there is a considerable quantity, medical men not unfrequently tell their patients that it does good, and say, by way of proof, "You know I have often given it to you as a medicine with great benefit." Granted, that it is a very valuable medicine; but it is quite possible to have too much of even a good thing, and when arsenic is inhaled for hours together, either all night or for some hours in the day, none can tell how much is inhaled, nor, if they did, would there be any power to regulate the dose, which varies according to the temperature of the room. Further, it is stated that "physiologists well know that arsenic is far more deleterious when breathed than when swallowed." The experience of years in this matter has taught me—and every day's experience confirms it more and more fully—that papers containing very small quantities of arsenic are liable to produce most injurious effects in the course of time, although their onset may be completely hidden from casual observers, and even from medical men who have not given special attention to the chronic effects of arsenic upon the healthy body in contradistinction to the disease.

Arsenic, being volatile, is continually giving off poisonous exhalations. In a heated room it is more rapidly volatilised, and its effects are then all the more seriously felt. Dr. Orton, of Stepney, who wrote on the subject some years ago in the *London Review*, and who is quoted in *The Green of the Period*, makes the following remarks, "deduced from a very close and watchful experience": "That the arsenical particles or dust are more to be apprehended in dry weather and in heated rooms, although during summer, from freer ventilation, doors and windows being open, the poison is then comparatively innocuous." Nevertheless, I could give cases of most serious results from arsenic-papers in summer, although doors and windows were open continually. Dr. Orton goes on to say: "That heavy damp weather is the season of most peril, and that then, by a decomposition set on foot, the poison is insidiously conveyed to the system in the form of arsenuretted hydrogen gas; that this poison affects persons of all ages, but that it is remarkably obnoxious to infantile life; that arsenic so absorbed is not uniform in its action, varying from slight, little noticeable, up to serious symptoms; but that the mucous membrane is peculiarly the seat of its attack, as manifested in its simulation of the various forms of diphtheria, in producing ophthalmia, defective vision, nasal irritation, great thirst, short dry cough, even asthma, low fever, great prostration, and faintings." This clear testimony from a physician ought to carry weight when generally known, but it does not appear to have done much towards arousing the attention of the profession, if we may judge by their indifference to the subject ever since it was first brought under their notice fourteen years ago.

It needs to be explained that arsenic possesses the extraordinary properties common to musk and strychnine, of never lessening appreciably in quantity during any number of years, though continually giving off poison into the atmosphere. Hence, a paper which has been up for many years is no less dangerous than a comparatively new paper; on the contrary, it becomes increasingly dangerous with age, because the older it grows the more does the surface pulverise. It is generally believed that no harm results unless the paper powders off perceptibly on friction; but that is an error, for the dust may be so fine as to defy detection, except with the aid of a microscope; and even if there were no dust whatever, evil effects would still result from the evolution of arsenuretted hydrogen, which is stated to be "gaseous at the usual temperature of the air."

The fact that arsenic is frequently to be found in papers of all colours, and in those termed "colourless," can hardly fail to throw light upon many cases where physicians have been baffled by symptoms resembling arsenical poisoning, and yet could detect no visible sign of arsenic in the paper—supposing that they looked for it, which, it would appear very few have done hitherto. The same will apply to cases where green papers have been condemned and removed, but where, as in the instances already given, through great relief followed, recovery has not been satisfactory, for the all-sufficient reason that those papers were replaced by others containing arsenic, though in very much smaller quantities.

It is also frequently the case, that where symptoms occur similar to those produced by arsenic, the paper visible on the walls may prove to be free from this poison, while underneath it are concealed one or more arsenical papers; and the peculiarly volatile nature of arsenic is such that wherever it exists, it escapes and poisons the atmosphere—even when used to preserve stuffed birds under a glass case—a fact stated by a well known physician. I have recently met with an instance of very severe poisoning from a vivid green paper concealed under another paper, which had been the cause of unaccountable illness for several

years. I also know an instance where as many as thirteen papers were thus found, one over the other, in a bedroom, the occupants of which were alarmingly ill. The outer paper being visibly arsenical, I advised its removal, and then was discovered this odious accumulation of papers underneath, several of which were also arsenical. Immediate relief followed their removal. This pernicious habit of putting up new papers over old ones appears to be a very general practice in lodging-houses, to save labour and expense, but also in private houses it is constantly done, from false notions of economy, or else to get a job quickly finished. Even if there were no arsenic-papers in existence, it is an unclean and therefore an unhealthy custom which cannot be too strongly reprobated.

It being, then, proved that arsenic is frequently used in papers of various colours besides green, the only alternative left to those who would keep health, or regain it, is, to have every paper in their houses analysed, and on no account to put up any wall-paper in sitting-rooms, bedrooms, halls, or passages, without obtaining a certificate from some reliable analytical chemist that it contains no arsenic. I would especially caution the public that it is most important to employ a professional analyst, instead of trusting, as too many have done, to an ordinary pharmaceutical chemist, who is not of necessity an analyst by profession. I mention this, because I know instances where pharmacutists have failed to detect arsenic both in paper and in other fabrics, which were afterwards found to contain it in large quantities.

From the facts now given, it will be seen that the evil concerning which I write, is of still greater magnitude than if confined exclusively to papers containing green. In my former communication, I stated that, owing to the very general use of green-colouring, almost every house in the kingdom was probably more or less poisoned with arsenic; but with this additional evidence of the presence of arsenic in papers of all colours, it would appear that in some houses the atmosphere of many rooms (or even of all) may be poisonous. In such dwellings, what chance can the inmates have of health? A lowered condition of vitality and want of nerve-power is understood to be the predisposing cause of all disease, and it would perhaps be difficult to find any agent more capable of producing such results than arsenic. What, then, does this wide-spread system of poisoning tend to but gradual, sure decay and deterioration of the national health? and that by totally unnecessary and preventable means, which the Government of this country is bound on every public ground to deal with promptly and energetically. I have been carefully investigating this subject for nearly two years, having had fourteen years' personal experience in the matter, with special opportunities for close observation of the symptoms developed in the progressive stages of arsenical poisoning during the whole of that time; and I have no hesitation in saying that I believe every medical man in the kingdom is treating day after day numerous cases of disease, originating in irritation of the mucous membrane, which simulate almost every morbid condition under the sun (brain, heart, lungs, liver, kidneys and other organs being affected in turn), the true diagnosis of which would be "arsenical poisoning."

It must not be supposed that I would attribute all disease to one cause. There are, alas! only too many others at work besides; but it will at least be allowed that this constant inhalation of poisoned air, by lowering vital power, paves the way for the invasion of every conceivable ill to which flesh is heir, and may therefore be said to tend indirectly to produce illness of all kinds (as well as directly, by irritation of the mucous membrane), while it also aggravates very seriously diseases that have arisen from other causes. The facts I have given speak for themselves, and may serve to show how serious an amount of atmospheric poisoning and consequent injury to health, and even destruction of life, are going on in our midst, slowly but surely. It is to be hoped that public feeling may be speedily aroused, and universal indignation expressed that such wholesale murder, for it amounts to nothing less, should have gone on unnoticed and unchecked during the greater part of this century, in a country which considers herself foremost in the ranks of civilised nations. Its effects may justly be described, to use the words of a writer upon another subject connected with social science, as "the lowering of the physique of the nation, the deterioration of our constitution." According to the purity or impurity of the air we breathe, so are human beings influenced both physically and morally; crime itself lurks in poisoned dens; and if we surround man, woman, or child with a poisonous atmosphere, from whatever source, we hinder healthy development, lessen the capability as well as the desire for employment, and sow the seeds of physical and mental incapacity for every avocation of life.

DR. MICHAEL BEVERLEY has been presented with a handsome biscuit-caddy by the nurses of the Norfolk and Norwich Hospital on retiring from the office of House-Surgeon.

## ROYAL COLLEGE OF SURGEONS.

FROM the annual report of the receipts and expenditure at this institution from Midsummer-day 1870 to Midsummer-day 1871, which has just been published, it appears that the former amounted to £11,752 : 2 : 3, and the latter to £11,759 : 14 : 1, being an excess of £7 : 11 : 10 over the receipts. In the account of receipts, the largest amount is derived from fees paid for the several diplomas, amounting to £9,279 : 11. The next largest amount, £1,907 : 1, is derived from rents (£845 : 1) and dividends on investments (£36,000) £1,062. Elections into the Council, Court of Examiners, and Fellowship, yielded £262 : 10. The Trust Funds produced £290 : 3 : 2, and are included under the following heads:—Hunterian, £49 : 13 : 8; Jacksonian, £10 : 2 : 10; Blicke's bequest to the Library, £8 : 17; Blane's Naval Medals, £8 : 17; Gale's Annuity, £20 : 7; Clift Fund, £44 : 15 : 8; Erasmus Wilson Fund, £147 : 10.—The disbursements, which amounted to £11,759 : 14 : 1, were principally on account of fees paid to members of the Council, Courts and Boards of Examiners, viz., £4,377 : 18 : 6, and salaries and wages £3,387 : 8 : 10. The sum of £974 : 17 : 7 was paid for taxes, rates, and stamps, exclusive of postage. Pensions are put down at £457 : 3. Subjects, patients, bandages, and refreshments, £158 : 3 : 11. Law expenses, £146 : 10 : 10.

In analysing the list of Fellows, Members, etc., we find that there are now 192 Honorary Fellows, 434 who have attained that distinction by examination, 706 by election, and 2 *ad eundem*, viz., Messrs. Kelburn King and Wm. MacCormac, making a total of 1,334, in whom the elections into the Council are vested. There are nearly 15,000 Members, 1,014 Licentiates in Midwifery, and 314 Licentiates in Dental Surgery.

To those about to undergo their examinations, the *Calendar* will be useful as giving all the questions submitted to the several candidates during the past year, whether for the Fellowship or Membership, together with much information.

## ASSOCIATION INTELLIGENCE.

## SHROPSHIRE ETHICAL BRANCH.

THE annual general meeting of the above Branch will be held at the Lion Hotel, Shrewsbury, on Friday, October 6th, at 1 P.M.; A. G. BROOKES, Esq., President, in the Chair.

Dinner will be served punctually at 3.30 P.M., for the convenience of the country members.

Gentlemen intending to read papers, or to be present at the dinner, are requested to notify their intention at their earliest convenience to

JAMES STYRAE, } Hon. Secs.  
EDWIN ANDREW, }

Shrewsbury, September 25th, 1871.

## SOUTH MIDLAND BRANCH.

THE next meeting of the above Branch will be held at the Town Hall, Worthingborough, on Tuesday, October 10th, at 2 P.M.

Gentlemen who intend to read papers or cases, are requested to forward the titles of the same forthwith.

J. M. BEVAN, M.D. } Honorary Secretaries.  
WM. MOXON, }

Northampton, September 11th, 1871.

## WEST SOMERSET BRANCH.

THE autumnal meeting of the above Branch will be held at the Railway Hotel, Taunton, on Tuesday, October 3rd, at 5 P.M. Dinner on the table at 5.15 punctually. Tickets 3s. 6d. each, exclusive of wine and waiter.

The following resolution was passed at the annual meeting:—"That with a view to choosing from members of the Branch their opinion, and to this effect, distinctly on special points of interest, a notice be sent to each member, at least one month before a general meeting of the Branch, of a question on a medical or allied subject to be proposed by the Council, on which at the said meeting each member will be expected to express his opinion; but having regard to the number of questions it is sought to elicit, no argument in supporting an opinion shall exceed five minutes in delivery, whether read by the writer, or dictated, or spoken extemporaneously."

The following question has been sent by the Council as the one on which opinions should be now asked:—"Does the application of Carbolic Acid favour the healing of wounds?"

Gentlemen intending to be present at the dinner, or to read papers afterwards, are requested to give notice to the undersigned, so that he may make the necessary arrangements.

W. M. KELLY, M.D., *Honorary Secretary.*

Taunton, September 11th, 1871.

## SOUTH EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE forty-first meeting was held at the Church Institute, Ramsgate, on Thursday, September 14th, 1871.

The following papers were read.

1. Mr. R. Hicks: Selection of Surgical Cases, with Remarks. [See page 383.]

2. Mr. S. Woodman: Case of Abdominal Aneurism, with Gangrene of the Right Leg. [See page 380.]

3. Dr. Parsons related a Case of Laceration of the Vagina from Fracture of a Glass Injection-Syringe, in which he had removed numerous fragments at intervals during a period of twenty-two months. He also exhibited a Syringe by Maw and Son, with a collar of vegetable ivory, which effectually prevented the advance of the piston through the nozzle, which was the cause of the accident in this instance.

Dinner.—The members and visitors afterwards dined together at the Granville Hotel.

## CORRESPONDENCE.

## THE NEW HOG-PARASITE.

SIR,—As in January last you were good enough to insert a letter from me in reference to the occurrence of a rare and remarkable entozoon in the hog, I feel sure that the record of some additional facts in relation to this subject will not fail to be of interest.

At p. 50, No. 254, of the JOURNAL, I have stated that the parasites discovered by Professor Fletcher, of Indianapolis, were examples of *Stephanurus dentatus*; but it will not surprise you to learn that other persons who have seen the worm have supposed it to be a new species of helminth. Thus, Professor A. E. Verrill, the distinguished zoologist, of Yale College, New Haven, Connecticut, has described it under the name of *Sclerostoma pinguicola*. His communications will be found in the September number of the *American Journal of Sciences*, for 1870, and in the more recently published "Report of the Connecticut Board of Agriculture." This Report has also been issued as a separate brochure by the Smithsonian Society, and is entitled *The External and Internal Parasites of Man and the Domestic Animals*.

But the most interesting fact which remains to be told is, that the *Stephanurus* has just turned up in Australia, in confirmation, as it were, of the anticipations expressed in the editorial notice of the JOURNAL, recorded at p. 44.

Through the kindness of Mr. Slack, President of the Royal Microscopical Society, I have had an opportunity of examining nineteen slides of unnamed entozoa, recently received from Sydney. They have been transmitted by the Secretary of the Agricultural Society of New South Wales, requesting that the various forms might be identified. A valuable paper by Mr. William Morris is also sent with them, describing the worms. This paper will be read before the Royal Microscopical Society at their next meeting on October 4th.

Having identified and named all the specimens, I am in a position to say that the *Stephanurus dentatus* is amongst their number, and that the facts thus brought out, in relation to the structure, development, geographical distribution, and obscure form of disease produced by this singular parasite, are of the highest interest, not alone to helminthologists, but also to practical agriculturalists and veterinarians, as well as to the scientific body of the medical profession.

I am, etc.,

T. S. COBBOLD, M.D., F.R.S.

Wimpole Street, September 1871.

## OBITUARY.

DUNCAN GREENHILL, L.F.P.S. GLASGOW, RUTHERGLEN.

ON August 20th, Mr. Duncan Greenhill, Surgeon, died at the age of 46 years. From the time when he received his licence, in 1855, he settled in the town of Rutherglen, and pursued his profession quietly and unobtrusively, securing for himself the esteem and confidence of those who sought his advice. In everything relating to the interests of the borough, and likely to benefit the people, he was ever forward in offering his aid.

## SAMUEL SOLLY, F.R.S.

THE many old pupils of St. Thomas's Hospital will hear with regret that their old teacher and friend expired suddenly on Sunday last, the 24th instant, at the residence of his daughter, Mrs. Money Wigram, in the 66th year of his age. After receiving an excellent preliminary education, he commenced his professional studies under the immediate auspices of Mr. Benjamin Travers, surgeon to St. Thomas's Hospital, to whom he was articled at the Royal College of Surgeons on May 3rd, 1822, in those "good old times" when hospital surgeons could take as many apprentices as they liked, and nearly always on the same terms, viz., payment of a premium of one thousand guineas to reside in the house, or half that amount if living out. Mr. Solly's father preferred the latter, and accordingly paid £525. Besides other advantages, it was generally considered that the pupil might look forward to becoming attached to the staff, and ultimately succeeding, as in the present case, to the higher surgical offices by seniority. On the completion of his apprenticeship, Mr. Solly was admitted a member of the College of Surgeons on May 9th, 1828. When the new charter was granted to that institution, he was one of the first elected a Fellow (December 1843). In 1856, he was elected a member of the Council of the College. In 1862, Mr. Solly was chosen Professor of Human Anatomy and Surgery, but did not continue his course beyond one year.

On the resignation of Sir William Lawrence as a member of the Court of Examiners, the Council, on May 27th, 1867, elected Mr. Solly his successor. In time, he became junior, and then senior, Vice-president; but, at the election of President, he was passed over in favour of Sir William Fergusson. There is no doubt the Council felt that, in such excited times as they were then passing through, they required the more powerful assistance of Her Majesty's Sergeant-Surgeon. Soon after this, Mr. Solly's health broke down, rendering it necessary for him to resign his chair as an examiner, and, we believe, also some of those lucrative appointments which he held in the city where he had long practised his profession. In 1866 and 1867, he was President of the Royal Medical and Chirurgical Society.

Mr. Solly was deservedly well known and esteemed from his numerous and valuable contributions to the advancement of medical science, especially by his work on the *Human Brain*, his *Surgical Experiences*, an analysis of Müller on the *Glands*, and many papers and lectures on surgery, etc., in the journals. By his death, a vacancy is created in the Council of the Royal College of Surgeons, which will not, however, be filled up until the annual meeting in July next.

Mr. Solly leaves a widow and family of sons and daughters to deplore his loss.

## ALEXANDER MACDOUGALL, M.B., C.M.

DR. MACDOUGALL died in the Edinburgh Royal Infirmary on September 5th, of diphtheria, after an illness of nine days. He was the son of the late John Macdougall, D.D., Minister of Lochgoilhead, and came to Edinburgh to study medicine, where, after a distinguished career as student, he graduated in August 1870. The following winter he obtained by competitive examination the post of resident-physician to the clinical wards of this Infirmary. Here, by his assiduity, kindness, and gentleness, he won the esteem and respect of all with whom he came into contact. In the same winter he was elected president of the Royal Medical Society, whose good he had ever at heart, and from which, he said, he had gained many advantages.

## RICHARD FILKIN, M.D., RICHMOND, SURREY.

RICHARD FILKIN was born at Great Berkhamstead in November 1775. His father was Lieutenant Filkin, R.N. In July 1790 he commenced his medical education under Mr. Dundas (afterwards Sir David Dundas, Bart.), Sergeant-Surgeon to King George the Third. Seven years later, Richard Filkin entered on his medical and surgical studies at St. George's Hospital, and passed as Member of the Royal College of Surgeons in 1803. He then entered the army, and ultimately became Surgeon of the North Gloucester Militia; and in 1815, the regiment having been disembodied, he was placed on half-pay, which he retained to the time of his death.

Being relieved from military duty, he settled in private practice at Tetbury in Gloucestershire, where he resided about fourteen years. After he had left Tetbury he went to Glasgow, and took his degree of M.D. at the University. He never practised after this, but occupied his leisure in travelling on the continent of Europe. He eventually settled at Richmond, and where he died on the 15th inst., in the ninety-sixth year of his age.

Dr. Filkin was a man of considerable intelligence and of agreeable

conversation. As a medical officer of the army, his zeal and energy occasioned him to be well thought of at the Army Medical Board, especially for his *Code of Diet for the Army*.

## WILLIAM HENRY WRIGHT, M.R.C.S.E.

MR. W. H. WRIGHT was born in Hackney in 1822. After studying at Guy's Hospital, he became a member of the Royal College of Surgeons and a licentiate of the Society of Apothecaries in 1845. He subsequently settled in practice in Clapton Square, and held the appointment of Divisional Surgeon to the Hackney Police, having also a very extensive private practice in the neighbourhood of Hackney. In private life he was much respected, being a most genial and kind-hearted man, and in his profession he enjoyed the confidence of all those whom he attended. Mr. Wright left his residence on September 19th for the purpose of taking a short tour through North Wales. On the 22nd, whilst in the neighbourhood of Festiniog Falls, he was walking upon the cliffs, and had descended a little below the summit of the precipice overhanging the Falls, when, the ground giving way, he was precipitated into the waters below, a depth of fifty feet. Seven wounds upon the head testified to his having struck against the rocks. An inquest was held on Monday the 25th, when the following verdict was returned. "Accidentally killed by a fall from a precipice at Cymfael Falls, Festiniog."

## MEDICAL NEWS.

## MEDICAL VACANCIES.

THE following vacancies are announced:—

ATCHAM UNION, Salop—Medical Officer for the St. Mary's District.  
BRISTOL, City of—Medical Officer for District No. 2.  
CHARING CROSS HOSPITAL—Assistant Physician.  
CORNWALL LUNATIC ASYLUM, Bodmin—Assistant Medical Officer.  
COTON HILL INSTITUTION FOR THE INSANE, near Stafford—Assistant Resident Medical Officer.  
GAINSBOROUGH DISPENSARY—House-Surgeon.  
GREAT WESTERN RAILWAY—Surgeon for the Leamington District.  
GUEST HOSPITAL, Dudley—Resident Medical Officer.  
INSPECTOR OF ANATOMY for the Provinces.  
LIVERPOOL INFIRMARY FOR CHILDREN—Honorary Assistant Medical Officer.  
LIVERPOOL NORTHERN HOSPITAL—House-Surgeon.  
MACCLESFIELD—Certifying Factory Surgeon for.  
MACCLESFIELD DISPENSARY—Medical Officer.  
MANCHESTER ROYAL INFIRMARY—Physician's Assistant.  
MAYO INFIRMARY—Surgeon.  
NEATH UNION, Glamorganshire—Medical Officer and Public Vaccinator for the Llangoyd District.  
NORTHERN HOSPITAL, Liverpool—Physician.  
OMAGH UNION, co. Tyrone—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Eastern Division of the Omagh Dispensary District.  
PEMBROKE UNION—Medical Officer for District No. 5.  
POCKLINGTON UNION, Yorkshire—Medical Officer and Public Vaccinator for the Pocklington No. 1 District.  
QUEEN ADELAIDE DISPENSARY, Bethnal Green—House-Surgeon.  
RATHDOWN UNION, co. Dublin—Medical Officer for the Killiney Dispensary District.  
ROYAL INFIRMARY, Edinburgh—Resident Physician, Clinical Wards.  
ROYAL ORTHOPÆDIC HOSPITAL, Oxford Street—Resident House-Surgeon and Apothecary.  
SHROPSHIRE EYE AND EAR HOSPITAL, Shrewsbury—Physician.  
UNST, Shetland, Parish of—Medical Officer.  
WARMINGHAM UNION, Wilts—Medical Officers and Public Vaccinators for the Corsley and Warmingham Districts and the Workhouse.  
WARNEFORD HOSPITAL, Leamington—Surgeon.  
WARRINGTON DISPENSARY—Resident Surgeon; Apothecary.  
WESTMINSTER HOSPITAL—House-Physician.  
YORK COUNTY HOSPITAL—House-Surgeon.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

CORSCADDEN, Mr., appointed Apothecary to the City of Dublin Hospital.  
HENRY, E., M.D., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Aughnacloy Dispensary District of the Clogher Union.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

## DEATH.

TOONE, Henry, Esq., Surgeon, at Whitwick, Leicestershire, aged 38, on Sept. 12th.

THE MARQUIS OF HERTFORD has been elected President of the General Hospital, Birmingham, for the ensuing year.

THE LORD BISHOP OF RIPON will preach the anniversary sermon on behalf of the Derbyshire General Infirmary.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.

**WEDNESDAY** ..... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY** ..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.

**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY** ..... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**WEDNESDAY**.—Obstetrical Society of London. 7.30 P.M.: Council Meeting. 8 P.M.: Dr. Copeman, "On Cases in Practice"; Dr. Braxton Hicks, "On the Contractions of the Uterus throughout Pregnancy: their Physiological Effects, and their value in the Diagnosis of Pregnancy."; and other papers.

## EXPECTED OPERATIONS AT THE HOSPITALS.

**LONDON HOSPITAL**, Wednesday, October 4th, 2 P.M. Removal of Tumour occupying the Nostril, Orbit, Temporal and Zygomatic Regions of Left Side, by Mr. Maunder.—Removal of Naso-pharyngeal Polypus; Operation for Ununited Fracture of Femur, by Mr. Couper.

## NOTICES TO CORRESPONDENTS.

**All Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.**

**CORRESPONDENTS**, not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS**.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**J. X. (Barnes)**.—It would hardly be advisable to comply with our correspondent's request. The honour in question is reserved for men of the very highest eminence, and for them only.

**Mrs. THOMAS MORGAN (Madeley)**.—Apply to Mr. Becke, Northampton; or Dr. Ford Anderson, 28, Buckland Crescent, Belzize Park, London, N.W. Mr. Fairlie Clarke's address is 2, Curzon Street, London, W.

## GEOGRAPHY OF PHTHISIS: A DISCREPANCY.

**Sir**,—Your article on the Geography of Phtisis, and abstract of Dr. Charlton's interesting paper, in the JOURNAL, afford materials for much reflection. Although the causes which procure for certain localities a complete or partial immunity from phthisis remain as yet unknown, we may still hopefully avail ourselves of our limited knowledge in the hygienic treatment of those patients whose history leads us to fear the development of some constitutional taint. If it should prove that a residence in such a favoured locality tends to arrest this development, we shall have discovered a fact in preventative medicine of great value to the inhabitants of those islands. As, however, it would be impossible to send the mass of our correspondents to Iceland, the Andes, or the Kirghis steppes of Russia, it becomes expedient to inquire what places in our own isles hold out the greatest chance of escaping from this malady. The investigations of Dr. Edwards Crisp and Mr. Haviland promise to render us great assistance in this matter. Referring to an article on the Influence of a Moist Atmosphere in the Production of Pulmonary Consumption, published in the *St. Andrew's Transactions* for 1869, Dr. Crisp there states "Great Ouseburn, in the county of York, is one of the places in England where phthisis is most prevalent." Turning to Mr. Haviland's coloured map, published in the JOURNAL at the beginning of this year, a considerable portion of that Union is found to be shaded dark, indicating a district where phthisis is not below the average frequency. If investigations into the geography of disease are to be made available for its prevention or cure, it seems of the first importance that the facts obtained should be most carefully sifted and recorded. This discrepancy, existing as to the very threshold of the inquiry, seems worthy of remark. Perhaps Mr. Haviland or Dr. Crisp, who have evidently bestowed much labour and study on this subject, can assist us to a satisfactory explanation. I am, etc., LEONARD ARMISTEAD.

**ARMBRISTAL PAPER**.—Early Hart's well and another communication on this subject in this day's JOURNAL. The author of the paper is, as we have stated, not a professional man, but the influence of his statements is touched by an eminent physician. Our correspondents might apply to Dr. Apjohn or Dr. Cameron, Dublin.

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

## MEDICAL WOMEN.

**SIR**,—Your article headed "Minerva Medica" is so fair in spirit and so wise in its counsels to lady aspirants for medical work, that I ask leave to add a few remarks; and having been for seven years Honorary Secretary to the Female Medical Society, I may be able to throw some light upon the question.

1. I would correct your writer in one point of fact, when he says that the seven ladies now studying medicine at Edinburgh have practically testified their opinion of the Obstetrical College of the Female Medical Society by keeping away from it. So far is this wrong, that two of those seven ladies are old students of our College, and took the highest honours of their years. One of them, Mrs. Thorne, subsequently practised as an *obstetric* in Bedford Square; but, when the opening for further study occurred at Edinburgh, she became one of the *septem contra Edinam*. Mrs. Thorne has done much in publicly pointing out the value of midwifery as a specialty for educated women, and the usefulness of our College in enabling women to fit themselves for the work. The other lady is the sister of Mr. Holroyd Chaplin, a well-known London solicitor, who is now one of the most active and useful members of the Executive Committee of the Female Medical Society.

2. I enclose prospectus of the College courses for its eighth annual session, from which you will see that the scheme of study is, so far as it goes, a sound and adequate one for "midwifery and the accessory branches of medicine"; and that the various subjects are taught respectively by medical gentlemen of adequate standing and ability.

3. The Female Medical Society would have done anything further that seemed feasible. In 1866, I applied to the Apothecaries' Company, but could get no encouragement whatever, and practically little information. I persevered until I was privately told by a member of the Court of Examiners that they meant to make it as difficult for the women as possible, and that they had made a mistake in letting Miss Garrett up. We understood that a full school, if organised for women, would be refused recognition on any practicable basis—such, for instance, as that on which the "Grosvenor Place School" worked for many years. The following are extracts from official letters which I obtained after some importunity from the Secretary:—

"No lectures are acknowledged by the Court of Examiners which are not delivered at a recognised medical school and to which is attached an hospital of at least a hundred beds." \*\*\*

And in another letter:—

"No lecturer will be recognised who is not connected with a recognised medical school. A medical school is not recognisable without a complete staff of lecturers, nor is the course of lectures acknowledged if delivered in a private room." \*\*\*

Such a school would require large means for its establishment, and a large income for its support; and as, in my opinion, there were not lady-students enough in the country to support it if established, I made no effort in that direction. Nor do I think that a charitable school is more required for women-physicians than for men-physicians. Even now I am of opinion that a complete medical school for women, if established, would stop for want of students. Numbers of ladies come to me about "entering the profession"; and when I advise them to set to work to pass the Arts examination at the Hall, or the preliminary women's examination at the London University, they disappear, and I hear no more of them.

4. Our Committee have never been able to adopt the notion of mixed classes; and on that and some other grounds we have not met with the co-operation of those who hold what are called more advanced ideas upon the subject. If there were any reasons of another kind for this absence of co-operation, your columns would be a proper place for these reasons to be stated and discussed.

4, Fitzroy Square, W., September 26th, 1871. I am, etc., JAMES EDMUNDS.

\* \* \* We read this as a total surrender of every material point at issue. 1. The prospectus forwarded is, in our opinion, absolutely farcical in its meagreness. The number of lectures in each course is not stated; there does not appear to be an adequate museum or a hospital attached; and there is a fatal failure to fulfil all the principal points which we described as compulsory for all recognised medical schools. The necessary full facilities for illustrating the lectures would seem from the prospectus to be non-existent. The Colleges cannot recognise what does not exist. 2. Dr. Edmunds's opinion apparently concurs with our own, that there are not enough lady-students in the whole country to support one ordinary medical school, on however small a scale. *Cadit questio*. An average of twenty students a year will keep a medical school in working order, as the experience of Lane's school, the Westminster, and others, shows. If there be not so many to be got together in the three kingdoms, our conclusion that this is really a very small question, magnified by loud talking and the spouting of frugal sympathisers, seems to be fully justified. No advocate ever dealt a more fatal blow to his own cause than the writer of this letter.

## MEDICAL RESPONSIBILITY.

**M. G. H. R.** puts the following curious case as a query. There are three of us practising medicine in this village. A farmer's wife was taken in labour, and the husband came for No. 1, who declined attending, as he was engaged for a shooting party, and did not wish to be detained. He then went to No. 2, and took him out to his house, about a mile distant. After being about an hour away, the doctor came back, and went to bed, it being about half-past five in the morning, the farmer leaving him on a saddle-horse. As our houses are close adjoining, I heard the whole transaction. About half-past six, the same man came for me, and I declined going, and told him to get the man he already had out. He said he would rather have me, as the other occasionally drank too much. There is no doubt this is quite true and notorious; but he was quite sober when he was called from bed that morning, and able to ride out and in again to and from his patient's house. I most positively refused to interfere in the case; and the man was obliged to keep to the practitioner he wished to throw over. Everything went on satisfactorily, although it turned out a breech presentation.

My reason for troubling you with these details is, that I wish to know—Could I have been compelled to go to this case? or could I have been held responsible for anything untoward that might have occurred? I think not; but the farmer, in conversation some time afterwards, was of the contradictory opinion. I would be glad to have your decision on the point in your answers to correspondents, at your convenience.

\* \* \* As there was a practitioner already in attendance, M. G. H. R. would clearly be absolved from occupying the delicate and unsatisfactory position which it was sought to impose on him.

**DR. STYRAP** (Shrewsbury).—The printer's notice has been called to Dr. Styrap's observation.

**CHIRURGUS SINE LIBERIS** entrusts us with the somewhat delicate mission of putting him in the way of obtaining a female orphan child to bring up and adopt. He will have no difficulty, we believe, if he address himself to one of the boarding-out committees established under the recent order of the Poor-Law Board; and we will, if he have his permission, forward his letter to Miss Hill, who has taken an active part in founding such a committee in the neighbourhood of which he speaks.

**MR. HAUGHTON**.—On this occasion, we fear we shall not be able to oblige Mr. Haughton, who makes his request in a somewhat unusual and inconvenient form.

TREATMENT BY CONDENSED AIR.

**SIR**.—Could I, through the medium of your JOURNAL, get information as to where and at what cost I could obtain a "pneumatic chamber" for the treatment of pulmonary affections by condensed or rarefied air? I should further like to know whether and with what results this mode of treatment had ever been tried in this country? I am, etc., ADOLPH WAHLTUCH, M.D.  
280, Oxford Street, Manchester, September 19th, 1871.

MEDICAL WITNESSES' FEES.

**SIR**.—When I am called on, by a policeman, to give an opinion (in writing or verbally) of a patient under my care, or to attend to give evidence at Petty Sessions, I forward a statement of the facts, and a claim of one guinea for each opinion or attendance, to the chief Secretary of State; and in every instance the claim has been allowed. I would suggest to your correspondent to try a similar mode of proceeding. I am, etc., J. R. SWANTON, M.D.  
Bantry, co. Cork, September 1871.

A FOREIGN HOSPITAL.

ACCORDING to the *Pall Mall Gazette*, the hospital at Kestel, where many British subjects are sent, seems to be a horrible place. Consul Barrow is almost a daily visitor there, and from all he hears the same complaint—scarcity of nourishment bordering on starvation, and an utter want of feeling or sympathy for the sick among the attendants. A portion of bread, under a pound, is given to the patients for twenty-four hours; the soup and meat are unfit to eat; if an application be made for a cup of water during the day, it is sternly and rudely refused; a towel is allowed to each patient, in the which he envelops his bread, washes his face, and wipes off from time to time any suppuration from a wound. The mattress allowed is a thin layer of straw in a sack laid on crossbars, forming the bottom of the bed. There is no pharmacy in the hospital, but the purchase of required medicaments is entrusted to the *infirmiers*.

DEGREES BY EXAMINATION WITHOUT RESIDENCE.

A PHYSICIAN asks.—Which continental degree of Doctor of Medicine is the best? I mean, of course, those of recognised Universities, where an examination is necessary. I have been informed that Brussels takes the first place; but should be glad of further information on the points. As the English Universities now require residence, it is quite impossible for any one in practice to obtain a degree from them.

A COUNTRY MEMBER.—Mr. George Busk is the President, and Messrs. H. Hancock and T. B. Curling are the Vice-Presidents of the College.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH: PRELIMINARY EXAMINATIONS.**—At the Preliminary Examinations in General Education, held by the Royal Colleges of Physicians and Surgeons of Edinburgh, for 1871-72, the following will be the books from which translations will have to be made:—In Latin, for the 21st October and 4th November 1871, as formerly, the 1st *Oration of Cicero against Catiline*, and the 2nd book of the *Æneid* of Virgil; for the 20th April and 20th July, 1872, *Cicero de Senectute et de Amicitia*; *Horatii Carmina*, Lib. II et III. The candidate, on each occasion, besides selecting one of the prescribed books, will be required to translate a passage from an unprescribed author. In Greek, for the 21st October and 4th November 1871, *Xenophon's Anabasis*, Book III, and *Homer's Iliad*, Book I; for the 20th April and 20th July, 1872, *Herodotus's History*, Book I, and *Homer's Iliad*, Book II. On each occasion, translation from both the books prescribed is required, also parsing and derivations of English words from the Greek. In French, for the 21st October and 4th November 1871, *La Fontaine's Fables*; and for the 20th April and 20th July 1872, *Voltaire's Henriade*. In German, the books required are, for the 21st October and 4th November 1871, *Schiller's Wallenstein's Tod*; and for the 20th April and 20th July, 1872, *Schiller's William Tell*. Parsing, and translation of short sentences from English into French and into German are also required.

THE RESULTS OF PRIMARY OPERATIONS IN MILITARY SURGERY.

**SIR**.—In the BRITISH MEDICAL JOURNAL of August 26th, in alluding to Mr. Mac Cormac's Notes on Ambulances, I am reported as stating that "primary amputation and excision of joints almost invariably failed." What I intended to convey was, that my experience in the Franco-German war enabled me to confirm the remarks which Mr. Mac Cormac had made relative to the failure of excision of the knee-joint, and the fatality attending secondary operations as compared with primary.

I may now add, that German surgeons at first were very conservative in their treatment of gun-shot wounds implicating the knee-joint; but at the close of the war the general opinion I heard expressed by them was, that in all such cases amputation should be done without delay.

Excisions of the elbow- and shoulder-joints often did well when the patients were placed under anything like favourable sanitary conditions.

I am, etc., G. W. McNALTIV.

Military Hospital, Stoke, Devonport, September 20th, 1871.

PILL-MAKING.

**SIR**.—Those of your readers who dispense their own medicines, will feel interested in knowing what a valuable medium the "glycerinum amyli" (of the present *Pharmacopœia*) is for working up drugs into pill mass. Sapo mollis, mucilage, or confectio senneæ, especially the latter, are all very well in their way; but when a medium is required which shall add scarcely anything to the bulk of the mass and yet shall hold together the most obstinate materials, there is none equal to this new one. It also possesses the desirable quality of keeping the pill from becoming dry for a longer time than others, and so the drugs are swallowed in a more active state. A marvellously small quantity suffices; the mistake is to use too much, when the pills will certainly run together. Hoping that these remarks may be of service to some. I am, etc.,

Lichfield, September 7th, 1871.

HERBERT M. MORGAN.

**NOTICE TO ADVERTISERS.**—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

**MR. H. CRIPPS LAWRENCE** (London), Dr. W. T. Greene (London), Dr. Horace Swete (Leamington), Dr. John Ogle (London).—As soon as possible.

POOR-LAW LUNACY FEES.

**SIR**.—In my opinion, "Medical Officer" has no claim for an extra fee in the case referred to by him, simply on the ground that no reference was made to lunacy in the order. I hope that, when next he has a clear case in hand, he will not take less than the usual fee of one guinea, which I consider is honestly earned by the responsibility incurred. I believe that the "Alleged Lunatics Friends Society" is still in existence, and that they would soon pounce upon any "medical officer" for any error in the certificate. As an examiner of lunatic paupers in a large town, I occasionally refuse to certify; but I invariably am paid for my attendance, and so I consider would "Medical Officer" be if the nature of the case had been mentioned on the order, as I conceive it should have been. I am, etc.,  
September 1871. A MEMBER.

**DR. THOROWGOOD** (London).—Thanks.

SUPERANNUATION OF POOR-LAW MEDICAL OFFICERS.

**WILL** the Editor, in his answers to correspondents, be good enough to inform an Associate whether the Poor-law Guardians have power to superannuate their medical officers as well as others? If so, at what age, and after how many years of service, or under what circumstances?

\*.\* The Poor-law Guardians can recommend for superannuation at two-thirds of his gross salary (*i.e.*, including extras, where extras are allowed) any poor-law medical officer who is incapacitated by ill health or advanced age from performance of his duties.

THE MIDDLESEX HOSPITAL.

**SIR**.—In the list of candidates for the Assistant-Surgeoncy to Middlesex Hospital, my name was, I presume accidentally, omitted. I am, etc.,  
London, September 26th, 1871. GEO. CHAS. COLES.

**WE** are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The New York Medical Gazette, Sept. 23rd; The New York Medical Record, Sept. 16th; The Boston Medical and Surgical Journal, Sept. 16th; The Madras Mail, July 15th; The Shield, Sept. 23rd; The Philadelphia Medical Times, August 7th; The Philadelphia Medical Independent, Sept. 9th; The Newcastle Daily Chronicle, Sept. 25th; The Preston Herald, Sept. 23rd; The Anti-Vaccinator, Sept. 30th; The Western Daily Mercury, Sept. 27th; etc.

**COMMUNICATIONS, LETTERS, ETC.**, have been received from:—

Dr. H. Charlton Bastian, London; Dr. J. Crichton Browne, Wakefield; The Medical Officers and Lecturers of the Westminster Hospital School of Medicine; Mr. Walter Rivington, London; Mr. Spencer Clarke, Whitchurch; Dr. W. T. Latham, Cambridge; Dr. Bradbury, Cambridge; Mr. Christopher Heath, London; Mr. Reginald Harrison, Liverpool; Mr. G. C. B. Hart, Clifton; Dr. T. M. Greene, London; Dr. Thorowgood, London; Mr. H. Allen, Sheffield; Mr. Richard Adams, Bodmin; Mr. Scattergood, Leeds; Mr. Hicks, Ramsgate; Dr. Parsons, Dover; Lady Hartry, Dundrum, Dublin; etc.

BOOKS, ETC., RECEIVED.

A Treatise on Physiology and Hygiene, for Educational Institutions and General Readers. By Joseph C. Hutchinson, M.D. New York: 1871.

On the Relative Powers of Various Substances in Preventing the Generation of Animalculæ or the Development of their Germs; with special reference to the Germ-Theory of Putrefaction. By John Dougall, M.D. London: 1871.

Thoughts, Philosophical and Medical, selected from the works of Francis Bacon; with an Essay on his Health and Medical Writings. By John Dowson, M.D. London: 1871.

A Complete History of the Case of the Welsh Fasting-Girl (Sarah Jacob), with Comments thereon, and Observations on Death from Starvation. By Robert Fowler, M.D. Edin. London: 1871.

An Introduction to Pathology and Morbid Anatomy. By T. Henry Green, M.D. London: 1871.

## Leeds School of Medicine.—

The WINTER SESSION will commence on Monday, and October. The Introductory Address will be delivered by T. CLIFFORD ALLBUTT, Esq., M.A., M.D., at twelve noon.

### LECTURES AT THE SCHOOL.

Anatomy—Mr. James Seaton, Dr. R. T. Land, Mr. J. A. Nunneley.  
Physiology including the Practical Course—Messrs. C. J. Wright and James Walker.  
Medicine—Dr. Chadwick, Dr. Heaton, and Dr. Allbutt.  
Surgery (including the Practical Course)—Messrs. Claudius G. Wheelhouse, F.R.C.S.; T. Pridgin Teale, F.R.C.S.; and T. R. Jessop, F.R.C.S.  
Chemistry—Mr. J. Chapman Wilson.  
Materia Medica—Dr. John Edwin Eddison.  
Midwifery—Mr. William Hall.  
Forensic Medicine—Mr. Thomas Scattergood.  
Botany—Mr. Edward Atkinson.  
Comparative Anatomy—Mr. C. G. Wheelhouse, F.R.C.S., and Dr. Allbutt.  
Demonstrations of Anatomy—Messrs. R. P. Oglesby, Charles Richardson, and John Horsfall, F.R.C.S.

Clinical Lectures are given by the Physicians and Surgeons to the Infirmary.

Ophthalmoscopic Demonstrations are given by Mr. T. P. Teale.

Demonstrations in Operative Surgery are given by Mr. Wheelhouse and Mr. Teale.

Demonstrations of Skin Diseases are given by Dr. Allbutt in the Infirmary.

Instruction in Vaccination is given by Mr. Holmes, one of the Public Vaccinators.

Besides the Infirmary, there is a large Dispensary and a Fever Hospital, both of which are open to Students of the School.

Special Prizes of the value of £10 each are given in the classes of Clinical Medicine, Clinical Surgery, and Forensic Medicine.

Silver and Bronze Medals are given in the Class Examinations.

Composition Fee, entitling to attendance upon all the required courses of School Lectures, forty-four guineas. The Fees for attendance upon the Medical and Surgical Practice of the Hospital are twenty guineas each for three years, and proportionally less for single sessions.

All applications for Tickets should be made to the Treasurer, Dr. HEATON, Clermont, Leeds. The Prospectus, and any further information about the School, may be obtained from the Secretary, Dr. EDDISON, 19, Park Square, Leeds.

## Tasteless Pills.—Cox's Patent.

Surgeons and Chemists supplied with an excellent Aperient Pill (the formula for which will be forwarded), coated with a thin non-metallic film, rendering each pill perfectly tasteless, it is felt a gross. Postage ad. They present an elegant pearl like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving in a short time, even in cold water. Any formula dispensed and covered, and samples, with a box of pills, from our collection which are kept in stock, for sending free on application.

Now ready a strong anti-acid coated Pill Case, resembling a pocket book, filled with Tasteless Pills (each 7 grains), from 14 daily used formulae, sent on receipt of remittance for £1 10s. Empty, 10s.

Cox, Dean, and Co., Tasteless Pill Manufacturers, Brighton.

## Dr. Durand's Medicated

FLANNELS.—See report of Dr. Bonington of Bromsea. "I hereby testify that I have examined Dr. Durand's Medicated Flannels, and fully tried its efficacy in cases of Rheumatism, Neuralgia, Strain, Paralysis, Lumbago, &c., and I confidently recommend it both as a preventative and curative of these ailments."—A. BONNIE.

Descriptive Catalogue of Dr. Durand's Health Bands and Medicated Flannels sent free of charge. MANTON and Co., 27, Cannon Street, E.C.

## Private Asylum for the Insane

of the MIDDLE and UPPER CLASSES, recently established at KIRKLANDS, BOTHWELL, LANARKSHIRE, within 14 miles of the Glasgow station of the Caledonian Railway. Is now ready for occupation, and has ample accommodation for more than One Hundred Patients.

Proprietor and Resident Physician, WM. DEAN FAIRBairn, M.D., formerly Medical Superintendent of the Old Royal Asylum, Montrose.

## St. George's Hospital Medical

SCHOOL.—The WINTER SESSION will commence on MONDAY, and OCTOBER, with an Introductory Address by Dr. JOHN CLARKE, at 2 p.m., in the Hospital.

Consulting Physicians—Dr. Wilson, Dr. Bence Jones, Dr. Pitman.

Physicians—Dr. Fuller, Dr. Barclay, Dr. John Ogle, Dr. Wadham.

Assistant-Physicians—Dr. Dickinson, Dr. William Ogle.

Physician-Accoucheur—Dr. John Clarke.

Consulting Surgeons—Mr. Caesar Hawkins, Mr. Cutler, Mr. Tatum.

Surgeons—Mr. Hewett, Mr. Pollock, Mr. Henry Lee, Mr. Holmes.

Assistant-Surgeons—Mr. Rouse, Mr. Pick.

Orthopaedic Surgeon—Mr. Brudenell Carter.

Orthopaedic Surgeon—Mr. Brodhurst.

A Maternity Department and Departments for Ophthalmic and Dental Surgery are arranged in connexion with the Hospital School.

### LECTURERS.

Descriptive and Surgical Anatomy—Mr. Rouse.

Physiology and General Anatomy—Dr. Wm. Ogle.

Physiological Histology—Dr. Cavafy.

Chemistry—Dr. Noad, F.R.S.

Physiological Chemistry—Medicine—Dr. Barclay.

Psychological Medicine—Dr. Bradford.

Surgery—Mr. Holmes.

Ophthalmic Surgery—Mr. Brudenell Carter.

Orthopaedic Surgery—Mr. Brodhurst.

Operative Surgery—Mr. Pick.

Pathology and Morbid Anatomy—Dr. Dickinson.

Midwifery—Dr. John Clarke.

Materia Medica—Dr. Dickinson.

Forensic Medicine—Dr. Wadham.

Dental Surgery—Mr. Vasey.

Botany—Mr. Child, F.L.S.

Comparative Anatomy—Dr. Cavafy.

Clinical Lectures by the Physicians and Surgeons every week.

A Medical Tutor is appointed to superintend the studies of the Pupils, and to hold periodical examinations.

On payment of one hundred guineas at entrance, a Pupil becomes perpetual to the Hospital Practice and all the Lectures.

Compounders pay forty guineas on admission, forty guineas for the second year, and ten guineas for each subsequent year, until their payments shall have reached one hundred and ten guineas, when they become Perpetual Pupils.

Gentlemen may enter separately to Medical or Surgical Practice, or to any single course of Lectures.

Dental Pupils are admitted on payment of £45.

Special Demonstrations of Skin Diseases and Lectures on Public Health will form part of the course of Lectures on the Practice of Medicine; and Students will be required also to attend the separate courses of Lectures on Pathology and on Psychological Medicine.

In connexion with the Lectures on Surgery, Demonstrations will be given on the Use of the Laryngoscope.

A separate course of Lectures on Diseases of the Eye, with Demonstrations of the use of the Ophthalmoscope, will be given, as well as Lectures on Orthopaedic Surgery, with Illustrations of Deformities and their Treatment.

Attendance on each of these courses will be required of Surgical Pupils.

In the Maternity Department, special Clinical Instruction will be given on Diseases peculiar to Women, and Practical Instruction in Vaccination to those who require certificates of proficiency.

The Appointments of House-Physician and House-Surgeon, which are held for twelve months, are filled up half-yearly from among the Senior Students, according to merit. These Officers also receive their Board and Lodging Fee, and no payment is made for the Appointment.

Clinical Clerks and Drivers are also appointed without payment, and provision is made that each Student should have the opportunity of holding these offices during his attendance.

The Office of Obstetric Assistant, Curator of the Museum, Medical and Surgical Registrars, and Demonstrator of Anatomy, with salaries of from £50 to £100 attached to each, are held out for competition annually.

The William Brown Exhibition of £50 per annum, tenable for three years, is bestowed after a competitive examination.

General Prizes are offered annually by Sir Benjamin Rossie, Dr. Ashall, and by the Treasurer of the Hospital. Sir Charles Clarke's "Good Conduct" Prize, the Thompson Medal, and the Johnson Memorial Prize, are also to be competed for each year.

A general examination of all the Students is held at the end of the Session, and Prizes and Certificates of General Proficiency are given to the most deserving.

Further information may be obtained from Dr. BARCLAY, the Treasurer, or Dr. WADHAM, the Dean of the Medical School, and from any of the Lecturers and Medical Officers of the Hospital.

## Middlesex Hospital.—The

WINTER SESSION for 1871-72 will be opened on Monday, October 2nd, at Three o'clock, with an Introductory Address by Dr. JOHN MURRAY.

### LECTURES FOR WINTER TERM.

Medicine—Dr. Greenhow, F.R.S. Surgery—Mr. De Morgan, F.R.S. Practical Surgery—Mr. Hulke, F.R.S.; Mr. Lawson; Mr. Henry Morris. Diseases of the Eye—Mr. Hulke, F.R.S. Physiology—Mr. Lowne. Anatomy—Dr. R. Liveing, M.A. Cantab. Chemistry—Mr. Heisch. Pathological Anatomy—Dr. Cayley. Anatomical Demonstrations—Dr. Liveing. College Tutor—Dr. Liveing.

Consulting Physicians—Dr. F. Hawkins; Dr. A. P. Stewart.

Physicians—Dr. Goodfellow; Dr. Thompson; Dr. Greenhow, F.R.S.

Obstetric Physician—Dr. J. Hall Davis.

Assistant-Physicians—Dr. R. Liveing, M.A. Cantab.; Dr. Cayley; Dr. John Murray.

Consulting Surgeon—Mr. Shaw.

Surgeons—Mr. De Morgan, F.R.S.; Mr. Nunn; Mr. Hulke, F.R.S.

Assistant-Surgeons—Mr. Lawson; Mr. Henry Morris.

Dental Surgeon—Mr. Tomes, F.R.S.

Assistant Dental Surgeon—Mr. Turner.

The Hospital contains 305 beds; there are special departments for Cancer (36 beds), for Diseases of the Eye, Diseases of Women and Children, and Syphilis. Demonstrations are given during the Summer Session on Diseases of the Skin and the use of the Laryngoscope. Three Clinical Prizes, including the Governors' Prize of twenty guineas, are awarded to those students who pass the most satisfactory examination at the bedside and in the post mortem room. Class Prizes are also given. There are likewise valuable rewards in the form of Six Resident Clinical Appointments. Students can avail themselves, free of charge, of the assistance of the College Tutor, and thus avoid, when preparing for the examinations of the Licensing Boards, the necessity of any private teaching apart from that of the Medical School.

General Fee for attendance on the Hospital Practice and Lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries, £90, which may be paid by instalments.

Fee for Dental Students, 25 guineas for the first year, and 15 guineas for the second.

Some of the members of the staff receive Students to board with them.

Further information may be obtained on application to the Treasurer, Dr. GREENHOW; the Dean, Dr. CAYLEY; or to Mr. LUCAS, the Resident Medical Officer, at the Hospital.

## Charing Cross Hospital

### MEDICAL SCHOOL.

#### SPECIAL EVENING CLASSES.

The Operations of Surgery—Edwin Canton, F.R.C.S.

Anatomical Demonstrations and Surgical Anatomy—Edward Bellamy, F.R.C.S.

Advanced Chemistry—C. W. Heaton, F.C.S.

Examination of the Urine, and the Clinical Use of the Microscope—Alexander Silver, M.D.

Auscultation, and the Physical Examination of the Chest—T. Henry Green, M.D.

These Classes are especially intended for gentlemen already engaged in Practice, and for advanced Students preparing for the higher examinations. For further information apply to the Dean at the Hospital.

A. J. POLLOCK, M.D., Dean.

## General Hospital, Birmingham.

### CLINICAL SCHOOL.

Perpetual Fee for Medical and Surgical Practice, Thirty Guineas.

Special Instruction will be given in Diseases of Women, and of the Skin; in the Use of the Ophthalmoscope and of the Laryngoscope; in Microscopy; Minor Surgery and Bandaging.

Opportunities of attending Midwifery Cases will be afforded. Fee £2 2s.

Prizes are awarded by the Medical Committee, and valuable Resident Appointments are filled by Students selected by Examination.

To enter, apply to Dr. WADE, Treasurer to the Medical Committee, 24 Temple Row, Birmingham.

## Berkhamsted School, Herts,

twenty-eight miles from Euston Square. There are Four Exhibitions from this School, each of the annual value of £60, tenable for 4 years at any Educational Institution. There are also Scholarships of £10 each tenable in the School.

Prospectus sent on application to the Head Master.

## INTRODUCTORY ADDRESS

DELIVERED AT

ST. THOMAS'S HOSPITAL, LONDON,

On October 2nd, 1871.

By F. LE GROS CLARK, F.R.C.S.,

Senior Surgeon to the Hospital; Member of Council and of the Court of Examiners in the Royal College of Surgeons of England; etc.

MR. TREASURER,—It is now many years—I do not care to say how many—since I exchanged my school-days for an artied student's life within the walls of our venerable Hospital. I may, even then, have indulged in the fond anticipation that, at some long distant future, I might realise the promotion which every hospital-apprentice of my time hoped for, but few attained. Yet I knew that unremitting exertion was needed in this competitive race, and I sought with others the mental relaxation and physical bracing which exercise on our river afforded. We used to come to Stangate; and many a time have I tripped, in the lightness of heart which the young and unwarped spirit alone knows, over the long shelving shore at low water to launch my boat. Even the ready credulity of boyhood would have rejected, as absurdly improbable, the suggestion that each flood-tide was then flowing over the site of the Hospital of future ages. Yet so it is; and I stand, with mingled feelings of deep emotion, on this spot to inaugurate the first session of a new era in the history of our old and honoured school.

It would ill become me, on an occasion like the present, to yield to those reflections, which naturally claim their influence over the mind of one who has passed the meridian of his days. It is the penalty of survivors to lament over the graves of those who are gone before; and how few of the number who began their career with me still remain, whilst all my honoured teachers have departed. How distant the prospect of the future was long years ago, yet how brief in retrospect. It scarcely needs an effort to carry me back to the time and scenes when, with buoyant hope and earnest purpose, I listened to the words which fell from the lips and watched the hand-skill of those I revered, ambitious to tread in their footsteps. Their place knows them no more; and in paying a passing tribute to their memory I am reminded that I am now the oldest teacher in this school, and the oldest officer or servant of the institution; and I am sensible how closely the next generation is pressing on—how soon I must give place to others, happy if, perchance, I linger still in the memory of some whose early promise I have hailed, and whose future career I shall continue to watch with abiding interest.

I have been led into this train of reflection by a consciousness that lapse of time has gained for me the privilege of addressing you on this interesting occasion. I shall not, however, indulge myself by giving further expression to meditations in which my younger hearers cannot be expected to sympathise. We are met together to celebrate a new birth, to inaugurate a new era, to renew our association with the familiar waters of our old river, from whose banks we have been divorced so long. He will not resent our presence, for, though we have encroached upon his bed, he flows by us with increased vigour, and in a purer and more wholesome current than of yore. All hail to our noble river, which secures to us immunity from encroachment, and an animated scene and health-giving breezes for our patients.

We have a noble Hospital, and the local habitation of its fitting accompaniment—a great Medical School. To you, Sir Francis, I offer, on behalf of my colleagues, our congratulations on the completion of this great work, which owes so much to your unflagging energy and devotion, and to express at the same time our appreciation of the enlightened spirit which has prompted the governors to make such admirable arrangements for the medical school. I believe, sir—nay, I have no misgiving—that our success will be commensurate with these preparatory advantages, and will leave no room for regret that this impulse has been acted on so liberally.

Although deputed to inaugurate a new era in the history of our Hospital School, I cannot be unmindful that there are many present on this occasion who sympathise with me in the memories of the past, and I may be excused if I devote a few moments to the retrospect; such indulgence—sentimental if you please so to call it—may not be without its apology, and even its useful application, in this utilitarian age.

The dawning history of St. Thomas's Hospital was not such as to promise the vigorous adolescence which it has since attained. It was

early in the thirteenth century—viz., in 1207—that an accidental circumstance gave birth to it. The canons of St. Mary Overy were burnt out of house and home, and took refuge in a building which they erected near at hand till their monastery was rebuilt; and the subsequent appropriation of this building for charitable purposes is the origin of our Hospital. A few years later, when under the patronage of the Bishop of Winchester, the ruins of whose palace still survive by the river-side in Southwark, it was scantily endowed by him.

The derivation of our name is somewhat obscure. It would appear, however, from the careful researches of Dr. Stone, who has contributed a *Short History of Old St. Thomas's Hospital* to our Reports, that the spital was first dedicated to St. Thomas, the martyr of Canterbury; and afterwards, with more orthodoxy, to St. Thomas the Apostle. The annual income of the Hospital towards the close of the fifteenth century was £343; and this was dispensed by a president, master, and brethren, the foundation being limited in its usefulness, and employed as an almshouse for the needy and infirm to die in, rather than as a refuge wherein the sick and wounded could be made whole. Nurtured thus through a prolonged infancy of more than three centuries, the institution was at last claimed by our orthodox and excommunicated King Henry VIII as church property, and was subsequently adopted and endowed by his youthful son Edward, who, shortly prior to his death, appointed the Lord Mayor and commonalty of the city for the time being as governors in perpetuity of the four royal foundations of St. Thomas, St. Bartholomew, Bridewell, and the Blue-coat School. Under their sheltering wing our Hospital has flourished and been enriched during the succeeding reigns. The old structure survived the great fire of London in 1666, and likewise a succeeding conflagration ten years later in Southwark; but towards the close of that century it was replaced by a new building, nearly £40,000 being subscribed for that purpose; and the statue of Sir Robert Clayton, which still graces our grounds, was then erected in commemoration of his liberal benefactions.

My own early memory of our Hospital dates back to a period prior to the erection of the two noble piles of building which flanked the new front square, in the midst of which the beautiful statue of our sixth Edward stood; and I used to traverse the old London Bridge from my city home, and listen by night, on my way from lecture, to the mysterious music of the water-works as the tide rushed through them with deafening noise; and little, indeed, did we then wren of the possibility that any power could arise of such influence as to compel our removal to another site. The interval of our abode in our late temporary refuge has been one of partial suspension of animation, and will, doubtless, ere long, be regarded as a blank in our existence, when the life we now renew shall be fully established and developed.

In the chronicles of our Hospital there are recorded many curious and interesting facts and events, as well as the names of both physicians and surgeons who were not only famous in their own day, but whose reputation has survived to the present time. Amongst the records, for which I am much indebted to our Medical Secretary, Mr. Whitfield, I find references to some singular customs and circumstances, which mark the changes that time has wrought in us and in our establishments. Thus towards the close of the sixteenth century, inmates of the Hospital, of notoriously bad character, were ordered to be punished at the cross erected within its walls before they were discharged; and we have an actual recital of punishment by whipping at the said cross being inflicted for misdemeanour in 1567. We also find that, in 1573, the morals of the patients were further cared for by a hand-mill being provided for them wherein to grind corn, that they might thus “be kept from idleness.”

In 1698, Mr. Elton, one of the surgeons, was suspended from his office for assaulting and beating one of his colleagues; and in consequence thereof an order of the Court of Governors was passed—which I presume is still in force—that in future if any officer strike or beat another officer he shall be expelled. This was certainly a vulgar way of resenting an offence, and is suggestive of the hybrid character of the barber-chirurgeon of that epoch. But it is recorded traditionally that the more polished physician, whose status in society permitted him to carry a rapier by his side, was also guilty of professional squabbling, ending in deadly feud, for Mr. Whitfield has in his possession a gold-headed cane, which was presented by one of our medical staff to his grandfather, in recognition of his services in arresting a mortal combat across his table by two of the physicians of this establishment.

I find the practice of specialties is recognised in the register of events for 1638, when £20 a year was voted to a surgeon—I suppose the Wilson of his time—for the special care and cure of scald-head. But the governors of that period showed a wise discretion in another allied act. It is well known that, before the great Cheselden lived, and adorned alike the profession and our Hospital, one of the most terrible

diseases to which the human frame is subject was rarely cured, because of the ignorance and incapacity of those who undertook the only means of affording effectual relief by operation. Now it appears that in the year 1700 a certain Dr. Cypriano, a native of Amsterdam, and educated at Utrecht, had acquired a reputation for this operation; and the General Court of the Hospital, prompted by a humane feeling, and careful also of the honour of their officers, requested the President to treat with this gentleman, with a view to his instructing two of their surgeons in his special operation. It is recorded that on several occasions he performed the operation in question at our Hospital with great success, and without fee or reward; but we do not learn whether his instructions were serviceable to his two pupils. I should think it doubtful, for little is learned in a complex operation, almost every step of which is out of sight, and in which an appreciation of all the attendant difficulties can be acquired only from an accurate acquaintance with the anatomy of the parts concerned. But anatomy was not then studied as it now is; and the benevolent object of the governors would have been more effectually attained had they rescinded an order of the court, issued a short time previously, that "no dead corpse should be dismembered."

The first impulse in the right direction, in the performance of this operation, was given by a French priest, Frère Jacques, in 1697, who acquired an European fame, but it remained for Cheselden to place it on the sure foundation which I have indicated; and it is much to say of our great surgeon, that his work on the subject, published in 1723, deserves to be a text-book still, and that, in every essential particular, this operation remains what he left it a century and a-half ago. What worthier subject, then, could be found for the sculptor's chisel, or to be held in cherished remembrance by the old St. Thomas's students? And beautiful as a work of art is the marble effigy of this fine old English surgeon, which now graces our entrance hall, the gift of those who delight to honour the great and good associated with their hospital and school.

At this period of our history a regular registry of the surgical pupils was kept by the apothecary, and the useful order of dressers existed. It may not be uninteresting to the gentlemen now holding that responsible office, to learn that they were then called "cubbs" in our establishment.

I have said that we can boast of many names of celebrity in the annals of our hospital. Thus, one of our physicians, Dr. Prujean, received special marks of honour at the court of Charles II, whose Queen he attended in a severe attack of fever. Dr. Richard Mead, whose courtly bust (also the gift of our old students) presents an interesting contrast to the artless and almost rude attire of his great surgical colleague, was an accomplished physician and a man of letters; and whilst an officer of our hospital he condescended to read lectures on anatomy to the Company of Barber-Surgeons. Engaged in a large and lucrative practice, the medical attendant of Queen Anne in her last illness, and the court-physician of George II, we learn that he was "highly respected, and as the patron and friend of the learned, universally admired."

It is recorded that Cheselden gave lectures on anatomy and surgery at the Hospital, but it was not until later, viz., in 1768, that Joseph Else, one of the surgeons, was officially appointed to lecture; and it may be said of him, that he was the founder of the systematic teaching of anatomy in St. Thomas's Hospital.

Dr. Mark Akenside was likewise an accomplished physician, and, in addition to being one of the officers of our Hospital, held the highest court appointment at the commencement of the reign of George III. But his reputation as a poet has survived his professional fame, and there is much of elegance and rhythm in his verses, and his language is choice and classical. But few can read his *Phaenons of Imagination* without some sense of weariness at the pompous and somewhat pedantic diction in which his really beautiful imagery is clothed.

In 1770, Dr. Foadye, whose portrait we possess, set us an example of diligence which I think few of my colleagues would be disposed to follow. He used to lecture daily on three subjects, viz., chemistry, materia medica, and the practice of physic; and these lectures, given at his own home, were delivered in three successive hours, commencing at seven o'clock in the morning.

Dr. Reynolds was a court physician of his time at the close of the last century; and Sir Gilbert Blane, another of our physicians, held a similar position in the next reign, and acquired much credit for his recommendation of a plentiful supply of lemon-juice to our troops engaged in the unfortunate Walcheren expedition.

The names of the last Ladies (whose age I, benevolent as I can just recall), and of Wells, the author of the elegant and conclusive monograph on the "Fermentation of Dew"; of Carrey, Chandler, and the Chines, bring me to the period of my own personal recollections, when

my honoured master, Mr. Travers, with Mr. Green and Mr. Tyrrell, were the surgeons, and Dr. Williams, Dr. Elliotson and Dr. Roots, were the physicians of our Hospital. They are all gone; and I can but record the great esteem in which they were held by all who knew them, as men of high scientific attainments, whose teaching and example have left their impress on the minds of many scattered throughout the length and breadth of this land. Of my own more immediate contemporaries, some are gone and some still survive, though they have withdrawn from amongst us. The grave has scarcely closed over one; and many will have learned, with grief but scarcely with surprise, of the death, one short week since, of Samuel Solly. I have known him since my boyhood, and we have been allies and colleagues throughout life; and I cannot recall a single hour during which the harmony of our intercourse has been interrupted. His compulsory retirement from professional duties, in consequence of ill health, occasioned our premature loss of his services here, and he carried with him the sympathy and kindly feeling of all his colleagues.

I may, perhaps, be permitted to express the excusable pride I feel in having now associated with me many of my former pupils, who have already made a name for themselves in the world of science; and even in the rising generation, St. Thomas's has no need to be ashamed of her children, and we both hope and expect she will rear many worthy successors of those I have named.

The last few words I have spoken remind me of the change which has come over the guiding principle of election to the offices of this Hospital since I was an arted student. Then an apprenticeship to one of the surgeons was deemed a necessary first step towards obtaining the appointment of Surgeon to the Hospital; and I have, naturally, a vivid recollection of all my contemporaries, who were competitors at the early start. Just as on the racecourse, one by one fell away from various causes; and speculation as to the future was often falsified by unredeemed promise or inability to stay. He who had the good fortune, as it was mine, to get an early start, might hope to win; but the necessary exertion was arduous and unrelenting; for, since the age of twenty, I have not ceased to take part in the teaching, though not the less a learner, in our hospital school. I mention this circumstance to exemplify the trying nature of the long probation and deferred promotion which attended this arrangement. The principle of free choice which now prevails—partly the cause, and in part the consequence, of the comparatively obsolete usage of apprenticeship—carries its own commendation with it; yet, I am free to admit that my conservatism does not allow me to dismiss this custom of other days without a word of apology for it. If we may judge by results, certainly the names of my immediate predecessors and teachers, and of their contemporaries at the sister hospital where the same usage prevailed, are some justification of that system. The training of the young men, who claimed their privileges from an apprenticeship of six years at the hospital, was such as to constitute a special preparation for their future duties, if they were naturally qualified to avail themselves of their peculiar advantages. Living for a lengthened period in the dissecting-room and wards of the hospital, they could not fail to acquire that familiarity with their after engagements, which no other training could so well supply. Indeed, the change in the practical working of the old system of apprenticeship is not, to my mind, an unmixed advantage. When practitioners in the country conscientiously performed their duty towards their apprentices, during their more protracted sojourn with them, our students used to come to London already in possession of preliminary information, and what I may term conventional details, in their profession, which are not so well acquired in our schools.

But times are changed, and with them the rising generation; and I neither expect nor desire to see a recurrence to the bygone system to which I have referred. Yet, I would venture to plead on behalf of the students whom we educate at our school; other things being equal, their prior claim to preferment is just and natural, and should never be ignored. In reputation, a hospital and its school are essentially linked together; the indirect advantages to the public derived from the latter are scarcely subordinate to the benefits directly flowing from the former; and the fame of a hospital must ever be commensurate with the reputation of its officers, as trustworthy teachers of the scientific practice of their profession.

But both teachers and pupils have their special responsibilities; and by their reciprocal fulfilment only, can successful teaching be secured. I believe that the public generally have but a very imperfect appreciation of the complex and extended course of instruction which medical education now embraces; and it is this increasing complexity which continually enhances the difficulty of the problem that is presented by the necessity of having some definite limit to the acquirement which a qualification to practise demands. It is not given even to the most gifted to become proficient in all the required subjects within the limit

of time which is assigned to study; and therefore it is obvious that a standard must be adopted which shall supply a numerical sufficiency of qualified practitioners. Whilst it is my sincere conviction that the College of Surgeons has honestly and faithfully fulfilled its functions, I have hailed with satisfaction, as I have sought to forward by my feeble influence, that scheme of conjoint examination which offers to the candidate one common portal by which he may enter the profession with a qualification to practise; whilst it leaves to our English colleges and universities the special privilege of conferring honorary degrees, after exacting proof of more advanced attainments.

I said that teachers have their responsibilities; and without presuming to dogmatise on this subject, I will briefly indicate the method which my own experience has taught me to regard as the most profitable, if not the most acceptable, mode of imparting professional knowledge. Teaching may be either exhaustive or suggestive; the former method, even if well and fully accomplished, can but instruct the student in facts, and supply him with reasons—good or bad—for the conclusions drawn from those facts. But this is not education, which consists less in supplying the learner with thoughts, than in stimulating him to think for himself. For

"Knowledge dwells  
In heads replete with thoughts of other men;  
Wisdom in minds attentive to their own."

Bishop Butler has remarked that the best writer—and, *à fortiori*, I should say the best *viva voce* teacher—is he who simply states his premisses, and leaves his readers to work out the conclusions for themselves. It is true that much of our teaching relates to facts; but these facts are, or ought to be, associated with principles; and the business of the teacher should be, in my apprehension, to exercise the mind of his pupil to work out for himself the relation between a principle enunciated and the facts by which it is supported. Trituration and digestion are as essential to healthy assimilation by the brain as by the stomach; and I am disposed fully to concur with an apologist of Coleridge's disjointed style of writing, when he eulogises its highly suggestive character, as contrasted with such exhaustive teaching as alone will satisfy him "who thinks that the epithets *teres atque rotundus* are the highest that can be applied to a scientific work; or who expects an author to furnish him with a complete system which he can carry away in his memory; and after it has received a few improvements from himself, may be hawked about to the public or to a set of admiring disciples."

I cannot help lamenting that there is much in the present method of teaching which is subversive of this suggestive principle for which I plead. Circumstances have, no doubt, conduced to this result; and chiefly the multitude of subjects crowding upon the attention of the student, which create a demand for the supply of information in such a form that it can be appropriated by an exercise of memory, without the invigorating effort which suggestive teaching stimulates. The results of such mechanical learning are not satisfactory; and the stereotyped acquirements of our students have induced the examining bodies wisely to modify their examinations, by rendering them as practical as possible; in order that the possession and exercise of a retentive memory may not be the chief qualification on which a student can rely for obtaining his diploma.

If, then, it be the duty of the teacher to stimulate the student to think for himself, it is no less incumbent on the latter to cultivate a spirit of self-reliance in learning his profession. He must, in short, educate himself, with the assistance and direction he will obtain from his teachers; and he will find that an infusion of enthusiasm into his work, will impart a pleasurable life and activity to the laborious details of his scientific pursuits, and render attractive that which would be otherwise irksome or repulsive in his studies.

I would now address a few words especially to those who are about to commence their hospital career. Your sojourn amongst us is fraught with momentous consequences to you, both moral and intellectual. The new life you enter upon and the new scenes you become conversant with, must leave their lasting impress on you for good or evil. Familiarity with suffering and death, in all their varieties and forms, constitutes a school of moral training which cannot fail to refine or to debase the moral sense—to strengthen or to enervate the character. Your future career will afford ample opportunity for applying the lessons of sympathy here inculcated; and of patient forbearance and gentleness in your relation with the sick and sorrowing, with whom so much of your life will necessarily be spent. These are grave responsibilities which will be yours, the importance of which you cannot too soon realise;—confidence of the most sacred character entrusted to your keeping; and opportunities for good beside and beyond your mere professional duties, from availing yourselves of which, no false humility, no mistaken apprehension should tempt you to shrink;—and which

you cannot evade without a compromise of truth, if you indulge the restless hope of restored health or of prolonged life, when you know that hope is vain. It is unnecessary I should pursue this subject further; if you obey the prompting of your better nature, and speak the truth with gentleness and candour, you will have your reward in peace of conscience; whilst it is beyond your ability to estimate the consequences to the dying sufferer who hangs upon your lips.

If I have paused to point out these as some of the moral lessons to be studied here, it is scarcely requisite that I should dwell on the necessity of improving every opportunity of mental culture now placed within your reach. The book of Nature is spread out before you in the dissecting-room, the laboratory, the wards, the museum; its pages are to be supplemented—not superseded—by the teaching and recorded opinions of other interpreters of the great Original. Drink deeply at the fountain-head; and gradually each new phenomenon or insulated fact will assume its true relation to others, as you view them blending harmoniously, and acting under laws, alike grand in their conception and simple and uniform in their operation, and thus bearing the impress of the infinite Intelligence and Goodness which planned them. It is thus, I venture to believe, that you will best cultivate the self-reliance and freedom from the slavery of authority, which are such essential qualifications for philosophical inquiry, and which are quite consistent with—indeed, ought to be the offspring of—true humility; for, that independence of character which has taught its possessor to scorn servile imitation, and to bow obsequiously to no man's dictum, should prompt him likewise to follow meekly the steady light of Truth, and to be the ever-ready servant and interpreter of Nature. I do not say your path is easy; but you may make it pleasant, by opening wide your heart in sympathy with your fellow men, and by cultivating your profession in an enlarged and philosophic spirit, instead of resting satisfied with the minimum of knowledge as your trading capital, acquired only for the pecuniary return it promises. You owe this to the noble calling you are about to follow; for, though I am aware that it has been said—and I fear with some truth in its application to the present time—that the "age of chivalry is gone, and that of sophisters, economists, and calculators has succeeded", yet is my faith unshaken in the elevating tone and influence of scientific pursuits, and in the full though tardy recognition of their claims, at length forced on the promoters of public education; unshaken also in the manly sentiment and independent principle which pervade the mass of my profession.

A few words more of personal application I am constrained to speak to my younger hearers, who will bear with me if their triteness deprives them of their relish. Most of you must be aware that your sojourn amongst us entails sacrifices on those who have sent you here,—sacrifices in the anxiety consequent on your being thrown alone amid all the temptations, frivolities, and dissipation of this great city; and a pecuniary sacrifice for your best and permanent interest. Confidence is placed in your redeeming the tacit or spoken pledge of honest and upright conduct. Will you abuse and betray that trust? Yet, wasted time and misemployed talents, and the indulgence of low tastes and vicious habits will be such betrayal, and bring grief and disappointment in return for self-denying love.

In fulfilling your obligations, I would simply ask you to be manly; and I will tell you briefly my interpretation of that comprehensive word. I should be untrue to my own instincts, and to the position I occupy as President of the United Hospitals Athletic Club, if I did not bid you cultivate manly exercise and sport. I admire the strong arm, the swift foot, and the bold bearing of the athlete. Yet these pastimes must be your recreation, not your occupation. But there is a higher phase of manliness, to which I especially refer. It is manly to be severe with yourself, and to deal lightly with the failings of your fellow-men. It is manly to admit, rather than to justify, either ignorance or error. Self-sacrifice is manly; but there is no element of manliness in the untruthful, the selfish, and the impure mind. It is both gentle and manly to esteem others better than yourselves, and to claim the respect which is your due by that courteous consideration for all around you which never fails to characterise the true gentleman. Above and beyond all, if you value your Bible, it is manly to avow it, and, by patient endurance of contradiction, and consistency of conduct, to prove that your faith is a real and living principle, regulating primarily your own deportment, and thus influencing your relations to all around you.

"To thine own self be true;  
And it will follow, as the night the day,  
Thou canst not then be false to any man."

But it is time that I bring to a close my brief tribute to the memory of the past, and the vindication of my confident hope in the future, of our ancient and royal foundation. Once the refuge of a few obscure monks; now reopened amid the pomp and glittering pageantry of State

officials, and graced by the presence of the noble and gentle in the land, and of our beloved Queen, who sympathises in the early interest the good Prince Albert took in our future home: nurtured erst in poverty, and restricted in usefulness; now possessed of a princely income, and folding within her wide-spread arms the destitute sick and maimed, whose only passport is suffering and want: yielding formerly her pittance of empirical skill and nursing to the few who sought it; now rich in the memory of so many whose labours within her walls have indelibly allied their names with some of the most enduring achievements of medical science; and (shall I not add?) proud of association with the imperishable name and work of the self-denying and gentle Nightingale:—such, in brief, is the history of this noble institution; and such are the children she has nurtured, who have repaid her fostering care by shedding a lasting lustre on our profession.

And what is the moral to be laid to heart from this history and these names? Shall we shrink in timid indolence from sustaining the weight of reputation thus transmitted to us? Shall we plead, with deprecating humility, that “there were giants in those days”, and sit down in listless indifference beneath the laurels they planted? Nay, not so. Let each and every associate in the work, with unselfish and untiring energy, devote himself to his allotted task. Let the substantial token of our affection for our Alma Mater, placed within her chapel-walls, be the pledge and symbol of that harmony of action for the common weal which no jarring note of discord shall disturb. Let private advantage and individual preferment ever yield, as in truth and honesty they should, to the fulfilment of the sacred trust to which every officer of this establishment is pledged when he takes office here. Let this be done earnestly, heartily;—I speak, sir, as one who has journeyed through weary years of discouragement, and is permitted, by grace, and not by right, to tread a few steps within the boundary of the promised land; let this, I say, be done earnestly and heartily, and who shall gainsay the confident anticipation, which it may be, perchance, my happiness to witness, though not to share in, that our ancient foundation, both hospital and school, shall emerge from its temporary eclipse, to shine with more than pristine brightness.

And, standing thus on this border-land, once more beside the old familiar river, from whose almy bed this stately edifice has arisen as if by magic; surrounded, too, by my trusted colleagues and many familiar faces which remind me of our earlier and happy association as pupil and teacher,—Imagination portrays for me, without an effort, the expanding vista of an illustrious future, worthy of such a history and such a habitation.

#### ST. GEORGE'S HOSPITAL.

DR. JOHN CLARKE, Lecturer on Midwifery, delivered the Inaugural Lecture. Having given a hearty welcome to the students, Dr. Clarke remarked that they were about to be introduced to a profession which had been truly called “Godlike” in its aim and tendency, unselfish and elevating in its practice, with duties great and laborious indeed, but allowing of pleasures which, if rightly esteemed and viewed, were equally elevating, grateful, and attractive—the grand aim and object of which was, or ought to be, the happiness and comfort of mankind. He was always proud to acknowledge the reciprocity of good feeling which had existed between the teachers and pupils of St. George's Hospital, and he trusted that in the future the dangers of lodging-house life might be avoided, giving comfort to the student without expense, freedom without licence, pleasurable enjoyment without dissipation. Great and well nigh insuperable difficulties, he well knew, lay in the way of composing such an object, but he did not despair of one day seeing a fairly advanced towards accomplishment. The hospital now possessed three hundred and fifty beds, large enough for all practical and scientific educational purposes; not so large as to weary and confine the student by its size and number of patients. There was a medical school, composed of buildings most admirably adapted to their purpose, and a museum almost equal in number and variety, and quite equal in the skilful arrangement of anatomical preparations, to any other in London. Having adverted to the multiplicity of the subjects with which the student would have to deal, their varied character, and the novelty of the language in which information was conveyed, the numerous examinations which the students would have to undergo, the lecturer said he could well understand all these perplexities, although in his time of studentship examinations were less numerous, and examinations less of a bore than they were at present. He insisted, though, strongly upon a knowledge of the classical languages, without which it was impossible to understand the nomenclature of disease, or the terms commonly used in medical books.

## EPIDEMIC AND SPECIFIC CONTAGIOUS DISEASES:

CONSIDERATIONS AS TO THEIR NATURE AND MODE OF ORIGIN.

*Being the Introductory Address delivered at University College, October 2nd.*

By H. CHARLTON BASTIAN, M.A., M.D., F.R.S.,

Fellow of the Royal College of Physicians; Professor of Pathological Anatomy in University College, London; Physician to University College Hospital; etc.

WE assemble to-day to inaugurate the work of a new session. Some of you are entering upon a new career, though others will have only to find your way again into what is, I trust, an already established routine of work and duty. The occasion, however, on which we now meet differs little in all essential respects from many others which have passed. Words of advice and counsel have been so often uttered to the new-comers, that I feel it would be comparatively useless again to take up such a well-worn theme. This view is further strengthened by the consideration that the able and judicious exhortations of many who have preceded me on similar occasions are still accessible. Without further excuse, then, gentlemen, I shall pass on to topics of another kind.

In medicine, even more than in other less complex sciences, it is well that imperfectly established general doctrines should be, from time to time, tested by the light of more recently acquired facts. Practice necessarily follows along the paths indicated by theory, and therefore it is in many cases all-important, even from a practical point of view, that true theories should be arrived at. The wider the applications of the theory, the greater is the necessity that it should be sound and based upon the best knowledge of the time.

I have determined to lay before you some considerations touching the nature and origin of epidemic and so-called ‘specific’ infective diseases. You will be impressed with the vast importance of the subject when you learn that nearly one-fourth of the total number of deaths occurring in Great Britain are due to these affections. As the Registrar-General has aptly pointed out: “Diseases of this class distinguish one country from another—one year from another; they have formed epochs in chronology; and, as Niebuhr has shown, have influenced not only the fall of cities, such as Athens and Florence, but of empires; they decimate armies, disable fleets; they take the lives of criminals that justice has not condemned; they redouble the dangers of crowded hospitals; they infest the habitations of the poor, and strike the artisan in his strength down from comfort into helpless poverty: they carry away the infant from the mother's breast, and the old man at the end of life; but their direst eruptions are excessively fatal to men in their prime and vigour of age. They are emphatically the *morbi populares*.”

No labour is too great, then, no pains should be spared, in order to arrive at just conceptions concerning the origin, nature, and mode of distribution of these scourges of humanity. Deeply impressed with the difficulties surrounding these great problems, and with the enormous importance of strengthening the foundations of our knowledge in respect to them, I was induced rather more than two years ago to take up the investigation of some questions which lay at the root of the whole subject. It seemed to me that no real advance could take place in our power of controlling these diseases until certain other great problems had been settled. What is the real cause of fermentation and putrefaction? Can the organisms which are associated with many of these processes arise *de novo*? These were questions the solution of which seemed to be of the utmost importance to the science of medicine, as well as to the cause of science generally. Thus incited, I resolved to study such much-disputed subjects for myself, with the view of arriving at some independent opinion.

As the results of this work—which to many may have seemed almost wholly unprofessional—have tended to strengthen certain views concerning the epidemic and specific diseases, and to make plain some points which were previously involved in obscurity, I think I cannot do better than attempt a somewhat hasty review of facts, which seem to point conclusively to the necessity of entertaining opinions with respect to some of these diseases which have been hitherto almost wholly ignored.

In the consideration of the nature and causes of disease, we have always to keep in mind two principal sets of factors. Each person exists with structural characters and functional properties which, though

in the main similar to those of his fellow men, have nevertheless individual peculiarities more or less marked. These may be inherent or acquired, habitual or occasional. Amongst these individual peculiarities are ranged what time-honoured custom has called the 'predisposing causes' of disease. On the other hand, man, with his individual peculiarities, lives in a world of change, exposed to the incidence of constantly varying external conditions, which, acting upon individual peculiarities, or upon the average human nature, become, in proportion to their deviation from the usual condition of things, so many 'exciting causes' of disease.

These two sets of factors must never be lost sight of. In the majority of cases, both come into operation in the production of the resultant morbid condition, although in others one or other of them alone may seem to be so potent as of itself to determine the morbid manifestation. The person who inherits a tendency to destructive lung-disease may develop this morbid condition under the influence of exciting causes which would scarcely affect another who inherits no similar weakness (predisposing cause). On the other hand, just as contact with boiling water, owing to the exceeding potency of the 'exciting cause', may determine a lesion of the skin in any individual (quite independently of the existence of a 'predisposition'), so may a person who is born with a weak and unstable nervous system become insane or epileptic, independently of the influence of any obvious exciting causes.

All diseases are, in fact, due to altered structure or molecular composition, whether visible or invisible, ascertainable or non-ascertainable. They are no longer regarded as entities. They are due to changes of state in some portion of the body, whereby the vital movement in the part is diverted from a normal into an abnormal mode of activity.

The complicated structure of the human body, and the allocation of specific functions to specific parts, necessitates, and has occasioned, a functional correlation and interdependence. Any disturbance of this normal balance of functions of necessity entails a definite sequence of pathological states and actions. A morbid change in an important organ, if it interferes with the function of the part, rarely exists alone. It sets up other associated effects, whereby the disturbed equilibrium of functions is more or less replaced by a new adjustment.

The effects are often well marked, though very variable, when the disease is one in which any notable alteration in the composition of the blood occurs. Supplying the materials of growth for all parts of the body, any changes in the composition of the blood are found, now to affect one organ and now another most profoundly. Before entering, however, upon the consideration of those diseases in which changes in the nature and quality of the blood form the most important condition of the disease, it will be useful to dwell for a time upon some of the more local pathological changes that occur in the more solid tissues of the body. The two sets of phenomena are closely related to one another. Morbid states which are at first purely local may, after a time, produce general diseases; and a general or constitutional disease frequently entails limited lesions in special parts. A wound or a local inflammatory process may lead to thrombosis, gangrene, and blood-poisoning; just as, following a reverse order, various febrile conditions may cause local lesions—now in one organ and now in another.

There are so-called 'specific growths', just as there are 'specific diseases' of a more general or constitutional character. The life-history of such growths as cancer and tubercle is a subject of great intrinsic interest; though the importance of their study is much enhanced by the fact, which I shall strive to make plain, that their modes of origin and distribution within the body are capable of throwing much light upon the origin and distribution of epidemic and specific infectious diseases amongst the community.

The term 'specific,' as applied to diseases, is confusing, and apt to carry with it a crowd of erroneous notions. Doctrines of 'specificity' have, however, been fashionable in medicine, though they are now growing more and more into disrepute. Thirty or forty years ago, amidst all the jargon concerning homoplastic and heteroplastic, euplastic and cacoplastic growths, would it not have been deemed rank heresy to profess a disbelief in the prevalent notions concerning the unalterable and 'specific' nature of cancer and of tubercle? Here were products altogether peculiar, and not derivable, as it was thought, from the normal tissues of the body—having laws of growth and distribution peculiar to themselves, and an origin which was shrouded in the mystery of a remote past. In view of this doctrine as to the specific and alien nature of the products, how natural was it that an undue stress should have been laid upon the fact that a tendency to the occurrence of such modes of growth may be hereditarily transmitted; how easily explicable is the facile and popular resort to the notion that, where multiple cancerous growths exist, the primary new formation has given rise to a seedling progeny by means of actual cancer 'germs'. Slowly but steadily these views have been undergoing a progressive modifica-

tion. The anatomical elements of cancer and tubercle are now known to have no special and peculiar characteristics, and they are believed to be as easily derivable from pre-existing tissues as are other non-specific morbid growths. A mere local change in the mode and intensity of pre-existing tissue-changes suffices to engender them. In the case of tubercle, this has been conclusively proved by such experiments as those of Dr. Burdon Sanderson and Dr. Wilson Fox. The latter says:—"M. Villemin's position, that tubercle is a specific disease, producible by tubercle alone, cannot, I think, be held to be true; nor can the method of inoculation be used as a test of the tubercular character of any pathological product; for the four guinea-pigs in whom the vaccine lymph was inoculated, and those inoculated with putrid muscle, and even one beneath whose skin I simply inserted a piece of cotton-thread, and also one of the four in which, following Dr. Sanderson's example, I inserted a seton, presented as intense and typical specimens of the disease as those on whom inoculation had been practised with the most typical grey granulations from the lungs or the meningeal vessels." What has now been (even experimentally) established with regard to tubercle seems also to hold good for such 'malignant' growths as recurrent fibroid, epithelial, and cancerous tumours or infiltrations. Statistics to which Virchow has drawn prominent attention seem to indicate most clearly the potency of 'exciting causes' in giving birth to these growths. Are they not found primarily, with by far the greatest frequency, in situations which are exposed to the action of irritative agencies, either external or internal, normal or abnormal? An amount of irritation which in some persons may lead to chronic inflammation or an hyperplastic overgrowth, will in others suffice to produce one of these so-called 'malignant' growths, even without the aid of any ascertained predisposition. The history of many cases of 'labial cancer', and of that to which chimney-sweeps are liable, speaks almost as plainly concerning the origin of cancer, as the results of experiments on the rodent animals do concerning one of the modes of origin of tubercle.

Is there anything specific in the mode of growth of these products, and in their subsequent distribution within the body of the affected person? Just as an erysipelas inflammation spreads by gradually inducing a similar morbid action in adjacent parts, so does a cancer or a mass of tubercle grow by a slower extension of the morbid modes of growth. We have no more to do with a kind of implanted something increasing by a multiplicative reproduction in the one case than in the other. In both alike there are deviations from the ordinary modes of growth, which gradually extend to adjacent healthy parts. Neighbouring lymphatic glands become affected in the case of tubercle and cancer-growths, just as they do where simple inflammations exist; and just as the change in the gland in the case of inflammation must be regarded as the result of a mere induced morbid action, rather than as the product of the multiplicative reproduction of a transmitted germ, so is a similar explanation open in the case of cancer and tubercle. Modes of growth which have been primarily induced may be also secondarily induced. The kind of agency, which is at least probably potential where the lymphatic system is concerned, or where particles of morbid growths come into contact with serous† or mucous surfaces, seems almost certainly operative when we come to consider that wider distribution which is occasionally brought about through the vascular system. The potency of the 'exciting causes' are here weakened, and new growths cannot be initiated in distant parts or organs by contact with disseminated particles, unless the 'predisposing causes' are favourable and there is an ability in the part to take on the morbid mode of growth. The action may be similar in kind to that which the transplanted fragment of epidermis exerts upon the ulcerated surface. This becomes covered, not so much by an actual increase of the imported fragment as by the formative changes which its presence incites. A crystal thrown into a mixed solution of saline substances will determine, by its mere presence, the crystallisation of similar materials from the solution; nay, it may determine, in addition, the crystallisation of other products whose modes of aggregation are more or less similar (isomorphous salts). The contact of any number of germinal particles with the tissues of an organ will not produce the formation of a new growth unless the molecular actions (or modes of growth) existing in the part are such as to make the transition an easy one. The mere presence of 'germs', therefore, is not all that is necessary. Cancerous masses may grow into the vena cava, and yet no cancer springs up in the lungs: the stomach may be absolutely infiltrated with cancer, and yet, as I have recently seen, no similar growths may exist in the liver.‡ Detail,

\* On the Artificial Production of Tubercle, 1868, p. 23.

† See Dr. Sanderson's 'Report on the Communicability of Tubercle by Inoculation' (Eleventh Report of the Medical Officer of the Privy Council).

‡ We find, therefore, that in the absence of any apparent predisposition, exciting causes, when potent, are sufficient to determine the occurrence of secondary growths in the same fashion that the primary growth may be determined. As the exciting

dangerous morbid condition known as 'malignant pustule.' The researches of M. Davaine\* and others have revealed the fact that this disease is essentially dependent upon the presence and multiplication of living organisms, closely allied to *Vibriones*, in the blood of the animals affected, and that similar organisms are also locally most abundant in the contagiously incited 'malignant pustule' of man. Unless this latter be destroyed in its early stages, the contained organisms spread throughout the body and the disease speedily proves fatal. Of late, moreover, attention has also been called † to Pasteur's researches on the subject of the very fatal epidemic which raged for fifteen years amongst the silkworms of France. This affection, known by the name of *pébrine*, is dependent upon the presence and multiplication of peculiar corpuscular organisms, called *Psorospermie*, in all the tissues of the body. Both these general parasitic diseases are highly contagious; both are contagious by means of organisms; and in both the virus does increase by self-multiplication within the body of the animal affected. What more suggestive evidence could there be as to the truth of the 'germ-theory,' say its advocates, than is supplied by the phenomena of these two diseases? Undoubtedly the evidence is irrefragable as to its applicability to these particular diseases; but then comes the question, whether they are comparable with the other affections to which the germ-theory is sought to be applied. And this question must decidedly be answered in the negative. These parasitic diseases are sharply distinguished from the others by the fact of their almost invariable fatality. Creatures or persons once affected in this way are, under ordinary circumstances, thenceforth on the road to more or less immediate death. Happily, however, no fatality of this kind is characteristic of even such highly contagious diseases as scarlet fever and small-pox, or any other of the maladies with which parasitic organisms cannot be shown to be associated.‡ But if living things were really present as causes of these diseases, then most assuredly ought they to conform to that fatal type which is almost inseparable from the notion of a general parasitic disease, and which we find exemplified by the course of *pébrine*, the 'blood,' and 'malignant pustule.'§ The fact then, that the general tendency in the acute specific diseases, is undoubtedly towards recovery rather than towards death, speaks strongly against the resemblance supposed to exist between them and the parasitic affections alluded to, and also against the hypothesis that they are dependent upon the presence of self-multiplying germs within the body. Such germs, when present, would be sure to go on increasing until they brought about the death of their host.

These considerations alone should suffice to inspire grave doubts as to the truth of the 'germ-theory.' And such doubts may be reinforced by many others. Thus, the several affections being distinct from one another, this theory demands a belief in the existence of about twenty different kinds of organisms never known in their mature condition, but whose presence as invisible, non-developing germs is constantly postulated, solely on the ground of the occurrence of certain effects supposed to be otherwise incapable of occurring. That, if existent, they are no mere ordinary germs of known organisms is obvious, because the presence of these has again and again been shown to be incapable of producing the diseases in question. Mr. Forster says, || "There is not perhaps on the face of the earth a human creature who lives on coarser fare, or to a civilised people more disgusting, than a Kalmuck Tartar. Raw putrid fish or the flesh of carrion—horses, oxen and camels—is the ordinary food of the Kalmucks, and they are more active and less susceptible of the inclemency of the weather than any race of men I have ever seen."¶ It has, moreover, been frequently demonstrated, that the organisms of ordinary putrefactions may be introduced even into the blood of man and animals without the production of any of these specific diseases.\*\* Yet is the 'Antiseptic System'

of treatment (good as it may be, irrespective of the germ-theory on which it has been based) pressed upon our attention on the assumption that the germs of putrefaction and the germs of disease are living organisms similar in nature. The strange persistency with which this view is advocated is not a little surprising when it entails the obvious contradiction that germs which do, under all ordinary circumstances, develop into well known organic forms, should, when concerned in the production of the diseases in question, induce all the effects supposed to depend upon their prodigious growth and multiplication, and yet never develop, never become visible. And whilst *Bacteria* and other organisms with which the unknown disease-germs are compared, flourish and reproduce in the much-vaunted germ-killing carbolic solutions,\* still carbolic acid continues to be recommended solely on account of its germ-killing powers, and the theory on which the practice is based is thought to derive support from the results obtained by the use of this agent. Surely no theory could be weaker on which to base a successful method of treatment; and if, as its distinguished originator says, † its general acceptance is principally hindered by the "doubt of its fundamental principle," then I would deliberately say that the blame, if any, cannot fairly be said to lie with those "who have opposed the germ-theory of putrefaction." The 'Antiseptic System' of treatment needs no support from a 'germ-theory'; it can be surely and unassailably based upon the broader physico-chemical doctrines of Liebig.‡

The last blow, however, seems given to the 'germ-theory' of disease, when we are told that the blood and the secretions in sheep-pox are not infective, though this disease is most closely allied to, and even more virulently contagious than, human small-pox. If germs had existed in this general disease, and their multiplication was the cause of it, then most assuredly would they have existed in the blood and in other fluids of the body; and yet, as Dr. Burdon Sanderson tells us, § "In sheep-pox all the diseased parts are infecting while no result follows from the inoculation either of the blood or of any of the secretions; the liquid expressed from the pulmonary nodules has been found by M. Chauveau to be extremely virulent—certainly not less so than the juice obtained from the pustules." Now, although in other of these diseases the blood does undoubtedly exhibit infective properties, still the ascertained existence of even one exceptional case amongst maladies so contagious as sheep-pox, seems to me absolutely irreconcilable with the truth of the 'germ-theory,' more especially when this theory was started principally to explain the phenomena of such highly contagious diseases. ||

Rejecting the 'germ-theory,' then must we confess our absolute ignorance on the subject (a course always better than the adoption of an untenable theory), or are there facts to guide us to another view as to the nature and origin of the poisons of these infectious diseases?

It surely is a vice in argument to suppose that the increase of the virus within the body in these diseases is only to be accounted for by a

originated in man's organism. Man himself has imposed the conditions favourable to their development. Man alone is responsible for their origin. Human intelligence, energy, and self-sacrifice may succeed in extirpating them, and may discover the means of preventing the origin of new forms not now in existence." This is undoubtedly a very much less objectionable form of the 'germ-theory,' though much additional evidence would be needed before we could accept the view that contagious diseases are due to the rapid multiplication of the contagious particles within the body of the creature affected. The non-contagiousness of the blood is as irreconcilable with this as with the other form of the 'germ-theory.'

\* See *Modes of Origin of Lowest Organisms*, 1871, p. 85. And in a recently published paper "On the Relative Powers of Various Substances in Preventing the Generation of Animalcules or the Development of their Germs," Dr. Douglass says, "If, as is alleged, germs are the source of putrefaction, then the strongest preventives must be the best antiseptics, and vice versa." Now, as seen in the table, carbolic acid occupies a very mediocre place as a preventive, therefore it is legitimate to conclude that it stands no higher as an antiseptic" (p. 13).

† BRITISH MEDICAL JOURNAL, August 26th, 1871, p. 225.

‡ These doctrines do not seem to have been adequately grasped by Prof. Lister. Fragments of organic matter are believed by Liebig to be capable of acting as ferments; he, however, holds that their potency is exterminated by heat almost as much as are the qualities of living ferments. The experiments with boiled fluids in bent-neck flasks, therefore, upon which Prof. Lister so strongly relies in proof of the germ-theory, prove absolutely nothing as between the two theories of fermentation of Liebig and of Pasteur. Amongst the atmospheric particles there are sure to be dead ferments in the form of mere organic fragments. Now the doubt that previously existed was, as to whether they could initiate fermentation and putrefaction, or whether the presence of living germs was absolutely essential. In the experiments with bent-neck flasks, both fragments and germs must be simultaneously excluded or admitted to the fluids. Professor Lister's readers might suppose that Liebig had no objection to his ferments being boiled, and that the issue lay between the relative efficiency of oxygen and living germs. (See Gerhardt's *Chemie Organique*, t. iv, p. 545.)

§ Report "On the Intimate Pathology of Contagion," in Twelfth Report of Medical Officer of Privy Council.

¶ Inoculation with the blood of a person suffering from measles has also in several cases failed to reproduce the disease. The different severity of small-pox taken in the ordinary way, and that induced by "inoculation" of the matter of a small-pox pustule, is also quite inexplicable in accordance with the 'germ-theory,' although both facts are quite reconcilable with the view about to be mentioned.

† *Nature*, 1870, No. 36, p. 181.

‡ Doubtless there are other general parasitic diseases amongst animals. In almost all the specific diseases to which man is liable, however, I have invariably failed to discover any trace of organisms in the blood. The experience of many other observers has been similar to my own in this respect.

§ See papers by Dr. Wm. Budd, in BRITISH MEDICAL JOURNAL, 1863.

¶ See *Med.-Chirurg. Rev.*, 1854, vol. xiii, where the supposed connection of diseases with processes of putrefaction is ably considered by the late Dr. W. Alison.

|| The *Bacteria* which are sure to be abundant in such food cannot, therefore, be the much talked-of 'disease-germs.' Such a diet is, of course, by no means recommended, and could probably only be borne in certain climates by persons who lead a very active life. Epidemic diseases are frequently most fatal when they once break out amongst a people whose diet is of this kind. See Dr. Carpenter, in *Med.-Chirurg. Rev.*, 1853, vol. xi, p. 173.

\*\* See, amongst others, Davaine in *Compt. Rend.*, Aug. 1864, and E. Semmer in Virchow's *Archives*, 1870. Dr. Lionel Beale is well aware of this fact, and he, accordingly, whilst adhering to the "germ-theory," promulgates it under a new form. He says (*Monthly Microsc. Jour.*, Oct. 1870, p. 205):—"Concerning the conditions under which these germs are produced, and of the manner in which the *rapidly multiplying matter* acquires its new and marvellous specific powers, we have much to learn, but with vegetable organisms the germs have nothing to do. They have
